Tuesday, September 22d. Address by the President, Dr. Wharton Sinkler, of Philadelphia.

A Case of Acute Spinal Paralysis: Death on the Twelfth Day, with the Account of the Microscopic Examination made by Dr. C. W. Burr, by Dr. Wharton Sinkler, of Philadelphia.

Polio-myelitis Acuta Adultorum, by Dr. William C. Kraus, of Buffalo.

A Contribution to the Therapeutics of Polio-myelitis, by Dr. V. P. Gibney, of New York.

Syphilis of the Spinal Cord, by Dr. Philip Zenner, of Cincinnati.

The Virile Reflex in Relation to Clinical and Forensic Neurology, by Dr. C. C. Hughes, of St. Louis.

Lead-poisoning with Special Reference to the Spinal Cord and to Peripheral Nerve Lesions, by Dr. E. D. Fisher, of New York.

A Case of Tumor of the Cerebellum in which Trephining was Done for the Relief of Pressure, by Dr. Philip Coombs Knapp, of Boston.

During the Meeting, Dr. William C. Kraus, of Buffalo, will exhibit a Neuro-topographical Bust.

Wednesday, September 23d. Gunshot Wound of the Left Cuneus with Complete Right Homonymous Hemianopsia, by Dr. J. T. Eskridge, of Denver.

A Case of Trephining and Excision of the Cortex for Jacksonian Epilepsy, by Dr. W. W. Keen and Dr. Charles K. Mills, of Philadelphia.

Five Recent Cases of Brain Surgery, by Dr. William A. Hammond, of Washington.

Astasia-abasia, by Dr. Philip Coombs Knapp, of Boston.

Tuberculous Infection of the Central Nervous System, by Dr. B. Sachs, of New York.

Subcortical Hemorrhagic Cyst Beneath the Arm and Leg Areas, with Remarks on the Diagnosis of Lesions

of the Motor Subcortex, by Dr. C. K. Mills, of Philadelphia.

The Diagnosis of Certain Forms of Intra-cranial Syphilis, by Dr. Landon Carter Gray, of New York.

1. A Case of Tumor of the Mesencephalon with Exhibition of the Brain; 2. A Case of Tumor of the Brain with Focal Epilepsy, by Dr. James Hendrie Lloyd, of Philadelphia.

The Electro-physiology of Reflexes, with the Description of a Hitherto Unknown Localized Physiological Phenomenon, by Dr. G. W. Jacoby, of New York.

Thursday, September 24th. Triple Personality, by Dr. Irving C. Rosse, of Washington.

A Case of Porencephalus in which Trephining was Done for the Relief of Local Symptoms. Death from Scarlet Fever. Exhibition of the Specimen, by Dr. De Forrest Willard and Dr. James Hendrie Lloyd, of Philadelphia.

Double Athetosis, by Dr. William Osler, of Baltimore.

1. A Case of Thomsen's Disease; 2. Removal of a Neuroma, Followed by Disappearance of Local Anesthesia of Fourteen Years' Standing, by Dr. G. L. Walton, of Boston.

Facial Hemi-hypertrophy, by Dr. William A. Hammond, of Washington, D. C.

Lithemia Considered in its Relation to Nervous Phenomena, by Dr. C. Eugene Riggs, of St. Paul.

Friedreich's Disease: Its Relation to Conducting Paths in the Cord, by Dr. David Inglis, of Detroit.

Fracture of the Eleventh Costal Spine, Followed by Injury of the Spinal and Sympathetic Nerve-supply of the Bowel in the Region of the Ileo-cecal Valve. Intestinal Hemorrhage and Death on the Seventh Day, by Dr. J. T. Eskridge, of Denver.

A Case of Unilateral Paralysis of the Lips, Tongue, and Pharynx, with the Presentation of Specimens, by Dr. G. M. Hammond, of New York.

The Fourth Annual Session of the Association of American Anatomists will be held at Washington, September 23, 24, and 25, 1891.

The following program has been arranged:

Wednesday, September 23d. The Fundamental Principles of Anatomical Nomenclature, by Dr. Burt G. Wilder, of Cornell University.

The Systematic Use of the Eye in Teaching Anatomy; Accompanied by a Demonstration of a Brain Model, by Dr. William P. Carr, of Washington.

Some Impressions on the Teaching of Anatomy to Medical Students, by Dr. Harrison Allen, of Philadelphia. Discussion to be opened by Dr. Dwight, followed by Dr. Baker.

The Fossa Prenasalis, by Dr. Thomas Dwight, of Harvard University.

Notes on the Hearts of Certain Animals, by Dr. Ida Hyde, of Chicago. To be read by Dr. S. V. Clevenger, of Chicago.

Thursday, September 24th. Recent Fissural Diagrams, by Dr. Burt G. Wilder, of Cornell University.

The Arrangement of the Supra-cerebral Veins in Man, as bearing on Hill's Theory of Developmental Rotation of the Brain, by Dr. William Browning, of Brooklyn.

Morphological Importance of the Membranous or Other Thin Portions of the Parietes of the Encephalic Cavities, by Dr. Burt G. Wilder, of Cornell University.

The Alleged Lateral Orifices, Communications of the Fourth Ventricle with the Subarachnoid Space: Are They Natural? by Dr. Burt G. Wilder, of Cornell University. Being a reply to part of Dr. F. W. Langdon's paper, "Homology of the Cerebro-spinal Arachnoid with the other Serous Membranes."

The Structure of Basis and Cement Substance, by Dr. Charles Heitzmann, of New York.

Serial Fetal Sections: Specimens and Remarks, by Dr. W. W. Gray, of Washington.

The Teeth of the Chiroptera, by Dr. Harrison Allen, of Philadelphia.

Specimens of Supernumerary Digits in Man and the Pig, by Dr. F. J. Shepherd, of Montreal.

The Relative Frequency of the Psoas Parvus Muscle in the Colored Race, by Dr. E. A. Balloch, of Washington.

Friday, September 25th. Certain Modifications in Plant Morphology, Produced by External Conditions, by Dr. W. P. Wilson, of Philadelphia.

Comparative Osteology of the North American Pygopodes, by Dr. R. W. Shufeldt, of Washington.

The Supra-condyloid Process in Man, by Dr. D. S. Lamb, of Washington.

Platycnemic Tibias, by Dr. Frank Baker, of Washington.

History of Anatomy as a Science, by Dr. G. W. West, of Washington.

Congenital Union of the Quadrate Jugal to the Mandible in a Cockatoo: Specimen and Remarks, by Mr. Fred. A. Lucas, of Washington.

Homologies of the Principal Bones, by Mr. Fred. A. Lucas, of Washington.

Several other papers are expected; one from Prof E. D. Cope, of Philadelphia; another from Dr. T. N. Gill, of Washington. Prof. D. J. Cunningham, of Dublin, will be present, and is expected to read a paper or make remarks on some subject.

The American Pediatric Society will hold its third annual meeting at Washington, September 22, 23, 24, and 25, 1891.

TUESDAY, SEPTEMBER 22, 8 P.M.

Address of the President.

How to Prevent Complications and Sequelæ in Scarlet Fever, by Dr. J. Lewis Smith, of New York.

Discussion on the Diagnosis of Pneumonia in Infancy and Early Childhood.

(1) The most diagnostic symptoms of the Early Stage of Lobar Pneumonia and the differential diagnosis from such diseases as Meningitis, Malaria, Scarlet Fever, etc., by Dr. T. S. Latimer, of Baltimore.

(2) The diagnosis of Consolidation of the Lung from Effusion (serous or purulent) and the differential diagnosis between Lobar Pneumonia and Broncho-pneumonia, by Dr. F. Forchheimer, of Cincinnati.

(3) The diagnosis of Broncho-pneumonia (acute and chronic) from Tuberculosis, by Dr. William Osler, of Baltimore.

(4) The diagnosis of Broncho-pneumonia from Bronchitis, also the Temperature Range in Acute Pneumonia,

both Lobular and Lobar, by Dr. L. Emmett Holt, of New York.

(5) Remarks by Dr. A. Jacobi, of New York, and by Dr. W. P. Northrup, of New York.

(6) General Discussion.

WEDNESDAY, SEPTEMBER 23, 11 A.M.–2 P.M.

Demonstrations.

(1) A Specimen of Congenital Heart Disease, by Dr. William Osler, of Baltimore.

Manifestations of "La Grippe" in Children, by Dr. Charles Warrington Earle, of Chicago.

The Treatment of Laryngeal Diphtheria by Calomel Sublimations, by Dr. Dillon Brown, of New York.

Further Report on Submembranous Local Treatment in Pharyngeal Diphtheria, by Dr. A. Seibert, of New York.

A Case of Ulcerative Catarrhal Dysentery, by Dr. W. D. Booker, of Baltimore.

Stricture of the Esophagus occurring in Children, with Report of a Case, by Dr. F. E. Waxham, of Chicago.

A Case of Pulmonary Abscess—operation and recovery, with Remarks, by Dr. Francis Huber, of New York.

THURSDAY, SEPTEMBER 24, 9 A.M.–2 P.M.

Demonstrations.

(1) Exhibition of Laryngeal Tubes for the Performance of Forcible Respiration, by Dr. J. O'Dwyer, of New York.

A Study of Fifty Cases of Chorea, by Dr. Samuel S. Adams, of Washington.

A Study of One Hundred and Forty Cases of Heart Disease in Children, (by invitation) by Dr. Floyd M. Crandall, of New York.

Dysentery in a Boy of Eleven Years—presence of Amœba Coli, by Dr. H. Lafleur, of Baltimore.

Scorbutus in Children, by Dr. W. P. Northrup, of New York.

Chronic Nephritis in Children, by Dr. Henry Jackson, of Boston.

Two Cases of Acute Primary Nephritis in Infants, by Dr. L. Emmett Holt, of New York.

Scarlatinal Nephritis in Children, by Dr. J. Lewis Smith, of New York.

The Application of Gavage in the Treatment of Uncontrollable Vomiting in Infants (by invitation), by Dr. Charles G. Kerley, of New York.

The Association of Congenital Wry-neck and Facial Hemiatrophy, by Dr. William Osler, of Baltimore.

Tuberculous Ostitis of the Hip, originating in Colorado, by Dr. John M. Keating, of Philadelphia.

A Case of Slow Heart in an Infant terminating in Fatal Syncope, by Dr. A. D. Blackader, of Montreal.

FRIDAY, SEPTEMBER 25, 9 A.M.–1 P.M.

The Etiology of Stomatitis Aphthosa, by Dr. F. Forchheimer, of Cincinnati.

Perityphlitis in the Young, by Dr. J. Henry Fruitnight, of New York.

Intussusception, by Dr. L. Emmett Holt, of New York.

A Case of Congenital Cretinism, by Dr. C. W. Townsend, of Boston.

A Further Contribution to Cirrhosis of the Liver in Childhood, with Post-mortem Notes and Microscopic Studies, by Dr. W. A. Edwards, of San Diego, California, and Dr. W. M. Gray, Microscopist, Army Medical Museum, Washington, D. C.

Female Physicians in Portugal.—Last year a woman was for the first time admitted to the medical profession in Portugal. This year four others have taken medical degrees.

ORIGINAL ARTICLES.

ON THE RESULTS OF TREATMENT OF SIMPLE FRACTURE OF THE SHAFT OF THE FEMUR.[1]

BY STEPHEN SMITH, M.D.,
OF NEW YORK.

AT the last meeting of the American Surgical Association, the following preamble and resolution were adopted:

"WHEREAS, In the treatment of fractures of the shaft of the femur the question often arises as to what is a satisfactory result in a given case; therefore, be it

"*Resolved*, That a committee be appointed by the President to report at the next meeting of the Association what in their judgment, under the methods of treatment now employed, should be considered as satisfactory results."

The following committee was appointed: Dr. Stephen Smith, of New York; Dr. D. Hayes Agnew, of Philadelphia; Dr. David W. Cheever, of Boston; Dr. D. W. Yandell, of Louisville; Dr. Charles T. Parkes, of Chicago; Dr. P. S. Conner, of Cincinnati; Dr. Charles B. Nancrede, of Ann Arbor; and Dr. Hunter McGuire, of Richmond.

The question referred to your committee has an important bearing upon the jurisprudence of surgical practice. One of the most frequent causes of prosecution of surgeons is the alleged mal-treatment of cases of fracture of the femur. Unfortunately, in the trial of these suits the testimony of surgeons appearing as witnesses has too often been contradictory. The effect of this want of uniformity of opinion among surgeons of equal opportunities for experience and observation has usually proved disastrous to the just determination of the question at issue. Courts have been led to regard expert testimony as only confusing, while juries have rejected it altogether.

It would greatly subserve the ends of justice in this class of cases if there were that harmony of views among surgeons, on the special subjects of litigation, that would secure the confidence of both courts and juries. And this consensus of opinion would undoubtedly have the greater weight if it was in the form of a precise statement, deliberately made, and authoritatively endorsed by a body organized like this Association. In this view your committee has endeavored to obtain the experience of individual members for the purpose of formulating conclusions that they may submit for adoption by the Association. Accordingly the committee issued the following circular to members, viz.:

"What should be considered as a satisfactory result (other than perfect union) in the treatment of a simple fracture of the shaft of the femur?"

The question was so framed as to elicit the answer that would be required in court. Thirty-four members replied, and their answers have been tabulated for convenience of reference. Although there are noticeable in these replies certain differences of opinion on the several points raised, these differences are by no means so great and irreconcilable as not to admit of being embodied in a general statement designed to harmonize and unite them for future reference. The committee has accordingly briefly reviewed the several questions raised, and has endeavored to secure a common ground on which the Association can take its position, and on which members can individually stand before the courts.

1. *Bony union.* The necessity of firm bony union as a result of the treatment of a fracture does not admit of discussion. The failure to secure this result, so frequent in fractures of the shaft of the femur, raises questions in each individual case quite foreign to the objects of this report. It is pertinent, however, to state that the amount of callus should not be taken as a criterion of the success of treatment. It may be so slight as not to admit of detection, or so abundant as to form a well-marked mass, and yet the function of the limb be completely restored. The practical question is as to its firmness.

2. *Relation of the long axes of the fragments.* It is the aim of the surgeon to restore the normal relation of the long axes of the fragments in order to prevent angular deformity. This he endeavors to accomplish by the exact apposition of the fractured surfaces, and by securing the normal curves of the shaft. But he finds that in the vast majority of instances he cannot effect his purpose. The exact apposition of the fractured surfaces is generally impossible; nor can the normal long axial line be restored with mathematical precision. Overriding of the fragments will, as a rule, occur in spite of the most accurately adapted appliances and the most assiduous care. Nor does this failure to secure perfectly accurate adjustment of the fragments, both as to the frac-

[1] Being the report of a committee read at the meeting of the American Surgical Association held at Washington, D. C., Sept. 1891.

tured surfaces and as to the long axis, imply loss or even impairment of function. For, if parallelism of the long axes of the two fragments is secured, notwithstanding the ordinary overriding of the fractured surfaces, the gait of the person and the strength of the limb need not be impaired by such union. We may conclude, therefore, that a satisfactory result is obtained when the long axis of the lower fragment is continuous with the line of, or with a line nearly parallel with the axis of the upper fragment, or, in other words, when there is no perceptible angular deformity at the seat of fracture.

3. *Correspondence of the anterior surfaces of the fragments.* On the correspondence of the anterior surfaces of the fragments depends the position of the foot. If these surfaces are on the same plane the foot will have its normal outward inclination from the center of the body, and in proportion as the anterior surface of the lower fragment deviates from the plane of the upper fragment will the foot incline from its normal position. If the deviation outward is considerable there will be permanent lameness of the patient. The result of treatment, therefore, to be satisfactory, requires that the anterior surfaces of the fragments shall be on the same plane, or, in other words, that the normal outward inclination of the foot shall be preserved.

4. *Length of limb.* The length of the injured limb when compared with its fellow was formerly regarded as the test of success of treatment. Hence, in the final estimate of the result the length of the fractured limb was carefully ascertained and compared with the uninjured limb, and the difference noted. The records of all past time show that shortening of the fractured limb was the universal rule, whatever the method of treatment pursued, and the question to be determined in each case was simply as to the degree of such shortening existing. The recent discovery of the natural discrepancy in the lengths of the lower limbs has considerably modified our estimate of this test of treatment. It now appears that a difference in the length of the lower limbs, once considered an evidence of unsuccessful treatment, is after all not incompatible with a perfectly natural formation of these limbs. It is established by careful measurement that 90 per cent. of healthy, uninjured persons have lower limbs of unequal lengths. This fact proves that shortening of one lower limb, as compared with the other, is the normal development of the skeleton of man. But the difficulty of estimating the value of shortening as a test is still further enhanced by the fact that one limb, as the left, is not invariably longer than the other, or the right. It appears that in 35.8 per cent. the right limb is the longer, while in 54.3 per cent. the left is the longer. It is, therefore, manifestly impossible in any case to determine the exact result of treatment so far as regards shortening. It might happen, if the limbs were found of equal length, that the naturally longer limb was fractured, and only the usual amount of shortening occurred, which equalized their length; or, if the shortening was found to be considerable, as an inch and a half, the difference might be explained thus: the fractured femur was originally the shorter, and the usual, unpreventable shortening occurring during treatment has been added to that already existing; or, again, we could explain those very rare cases in which the fractured limb is alleged to be found the longer after treatment, by assuming that it was previously much the longer, and that the shortening has not been sufficient to equalize the lengths of the two.

In view of these facts we must conclude that, within given limits of shortening, measurement of the limbs affords no accurate or reliable guide as to the success or failure of treatment. Those given limits have never been fixed by authorities, and even had they been agreed upon previously to the discovery of the natural difference in the lengths of the limbs, they would have had no substantial foundation. With these new facts to aid us, we are in a position to create a much more just standard, for it will have a scientific basis. In the first place, it must be accepted as a legitimate conclusion that if the amount of shortening does not exceed the average natural difference in the lengths of the limbs, viz., about one-half an inch, the result will be in accordance with the laws of Nature in the conformation of the lower extremities. In other words, such a result ought to be considered *perfect*. Secondly, if the shortening does not exceed the extreme limit of difference in the lengths of natural limbs, viz., about one inch, the result should be regarded as satisfactory. Thirdly, an unsatisfactory result, as regards shortening, exists only when the degree of shortening exceeds the greatest difference of natural limbs, viz., one inch.

5. *Lameness.* Lameness, limping, or a halt, after recovery from fracture of the femur, is a symptom of very variable significance. Some patients will have a limp in their gait with but one-fourth of an inch shortening, while others will not limp who have a half or even an inch of shortening. It is an important fact—bearing upon the question of how far shortening of the limb after fracture of the thigh, with lameness, is to be taken as proof of disability—that people who have, normally, one leg longer than the other do not limp, even when the difference has been found to be fully one inch. Undoubtedly, this failure of persons to recognize the natural discrepancy in the lengths of their lower extremities is due to the habit, early acquired, of adjusting the pelvis to neutralize the defect, with a slight compensatory curvature of the spine.

NAME OF SURGEON.	OPINION.	REMARKS.
W. W. Keen, Prof. Prin. Surg. and Clin. Surg. Jeff. Med. Col., Phila., Pa.	Perfect union with not over half or three-quarters of an inch of shortening, enabling the patient to walk without limping.	
John Ashhurst, Jr., Prof Surg. Med. Dept. Univ. Pa., Phila., Pa.	In the case of an adult: A useful limb without obvious limp or deformity, and with shortening of not more than one inch.	I have never seen, either in my own practice or in that of other surgeons, recovery without slight shortening (in the adult), though this shortening may be as little as from a quarter to half an inch.
O. H. Allis, Surg. Presb. and Jeff. Med. Col. Hosp., Phila., Pa.	Only such a result as permits the patient to assume his customary duties.	Shortening to the extent of an inch or more is not incompatible with great strength and usefulness. Outward angular deformity in the upper and middle thirds, even with slight shortening, results in feeble legs, and necessitates a cane or crutch.
N. Senn, Prof. Surg. Rush Med. Col., Chicago, Ill.	Proper axis of bone, useful joints, and perhaps from half an inch to an inch and a half of shortening.	
Roswell Park, Prof. Surg. Med. Dept. Univ. Buffalo, Buffalo, N. Y.	A useful limb with not to exceed half or five-eighths of an inch shortening, with joints which at the end of from ten to twelve weeks after leaving bed respond to all calls made upon them, and muscles which do the same.	
D. Hayes Agnew, Hon. Prof. Clin. Surg. Med. Dept. Univ. of Pa.	Union with shortening not exceeding three-quarters of an inch, with the normal curves of the bone little, if any, exaggerated.	Union after such a fracture, in the adult, without shortening, never occurs. The changes that take place at the seat of injury render such a result impossible. There is always an appreciable loss of osseous tissue at the ends of the broken fragments, corresponding to the extent of the blocking up of the vessels of the Haversian canals by coagula. There are cases of delayed union, from causes often inexplicable, and which, in order to renew the work of repair, sometimes require the rubbing together or attrition of the fragments. In cases of this nature the degree of shortening, after consolidation, will rarely be less than one inch, in consequence of the increased absorption of bone.
John Homans, Surg. Mass. Gen. Hosp., Boston, Mass.	Union in the line of the proper axis of the femur with a shortening of not more than three-quarters of an inch.	
Geo. W. Gay, Surg. Boston City Hosp., Boston, Mass.	In adults bony union with no great lateral deformity, and *not over one inch shortening*.	I never expect less than three-quarters of an inch shortening, and have never seen a case without some shortening. Under ten years of age the result is satisfactory if the shortening does not exceed three-quarters of an inch.
R. A. Kinlock, Prof. Surg. Med. Col. State of South Carolina, Charleston, S. C.	There should be no obvious deformity; the physiological functions of the limb, including all of the articulations, should be preserved, and the shortening should not be greater than half an inch.	
Christopher Johnston, Emeritus Prof. Surg. Univ. of Maryland, Baltimore, Md.	The best result is not a perfect union only, but a perfect coaptation of the fractured ends of the bone.	This coaptation, considering the mass of flesh surrounding the fractured bone, is very difficult indeed. The shape of the bone, itself arched, making a more decided arch with the femoral neck, is opposed to a straightening of the whole femur. A gentle *curve* of this bone under treatment in fracture, and the following by the lower fragment of the natural rotators outward of the upper iliacus and psoas magnus and the adductors, 1, 2, and 3, which all turn and keep outward the upper fragment above a point at which the fracture may lie, are well to bear in mind. If extension be employed the above precepts of curves must be kept in view, and shortening may be avoided, and continuity, even, be best promoted.
L. C. Lane, Prof. Surg. Cooper Med. Col., San Francisco, Cal.	Recovery with length of limb equal to what existed prior to the fracture, with some deviation from normal outline.	This can be obtained by traction and counter-traction in the extended position, traction to be made by weight, pulley, and rubber adhesive plaster, and counter-traction by the patient's body. The traction force will vary from ten to thirty pounds according to the age and muscular resistance of the subject, accurate adjustment and restitution to anatomical form being secured while the patient is deeply anesthetized.
John H. Packard, Surg. Penn. and St. Joseph's Hospitals, Philadelphia, Pa.	Perhaps it may be said, as the nearest approach to a definite standard, that in an ordinary case of fracture of the shaft of the femur, there should not be more than one-half or three-quarters of an inch of shortening to be detected by measurement. I should look much more at the ultimate effect upon the gait of the patient; I say *ultimate* because so often a degree of shortening, which at first causes a decided limp, is overcome later by a slight compensatory curve in the spine. Attention has been somewhat too much concentrated upon mere shortening to the exclusion of angular or rotatory displacement.	I do not think it possible to establish an exact standard of good result for fractures of the thigh, since that which could be easily secured in the case of a sober, quiet, and healthy person, might be wholly unattainable in one who was nervous and restless, or the subject of delirium tremens. The obliquity of the line of fracture does not, in my opinion, affect the result in any marked degree. Rotatory displacement, the toes being everted, makes a patient permanently lame. In this, as in almost all other fractures, the most fruitful source of bad results is the tendency of so many to adopt a routine treatment. If the requirements in each case were carefully studied, and the proper appliances and effective maintenance of the apparatus insured, I think good results would be obtained in a larger proportion of cases.
J. R. Weist, Surg. to St. Stephen's Hosp., Richmond, Ind.	In simple fractures of the shaft of the femur in the adult, union of bone without other deformity than from one-half to three-quarters inch shortening.	In patients under twelve years, I should consider union without shortening or other deformity a satisfactory result.

NAME OF SURGEON.	OPINION.	REMARKS.
John B. Roberts, Prof. Anat. and Surg. Phila. Polyclinic, Phila., Pa.	1. Absolutely firm union. 2. So little difference in length of the limbs that no *marked* limp occurs in walking. 3. Not much angular deviation in the normal line of the bone. 4. Not enough rotatory deviation to make a marked inversion or eversion of the leg or foot.	2. As from one-quarter to one-half inch difference in length often exists in normal limbs, that much shortening may remain after fracture in one of a pair of symmetrical legs without making the result unsatisfactory. Even greater shortening may remain after fracture of a long leg without making the result unsatisfactory; while a less amount occurring after fracture in a short leg will cause a decided limp and make an otherwise satisfactory cure seem unsatisfactory. I do not believe that any fracture of the shaft of the femur is likely to be cured without some shortening, though it may, I admit, be impossible to prove its existence during life. 3. Slight bowing is of no more importance than that often observed in uninjured femurs and tibias of adults.
A. Vander Veer, Prof. Surg. and Clin. Surg. Albany Med. Col., Albany, N. Y.	In oblique fractures we must expect some shortening, not to exceed one-half inch.	In a transverse fracture my experience has been that a very large proportion result in perfect union, with possibly one-quarter inch or so of shortening in some few cases.
Basil Norris, Surg. U. S. A.	Half an inch shortening would be to me a result entirely satisfactory.	Since the use of adhesive-plaster extension I have seldom seen so much as one inch shortage (when union took place in a reasonable time) in a case of single, simple fracture of the shaft of the femur . . . even though there be unnatural adhesions of the soft parts, and consequent limitation of the joint-motions, for these results are sequences of injury and repair that are unavoidable.
R. B. Bontecue, Surg. Marshall Inf., Troy, N. Y.	Not more than one inch shortening, and the original axis of the shaft restored without inversion or eversion of the foot.	
S. H. Weeks, Prof. Surg. Med. School of Maine, Portland, Me.	In adults, when the fracture is oblique, as it usually is, firm union with shortening of half an inch.	When the fracture is transverse, union occurs without shortening. My method of treatment is Buck's extension apparatus, with elevation of foot of the bed for counter-extension, and sand-bags on each side of the limb.
L. S. Pilcher, Prof Clin. Surg. Post-Graduate Med. School, New York.	In my experience the cases are exceptional in which a simple fracture of the shaft of the femur cannot be conducted to a cure with a shortening of less than half an inch; often in young subjects an appreciable shortening will remain.	I cannot, however, approve the idea of setting up any particular degree of shortening as a satisfactory or unsatisfactory result. Perfect restoration to the length that existed prior to the injury will, of course, be aimed at by every surgeon, and if he has done the best he could for his patient under the particular circumstances of the case, always variable—*i. e.*, in no two cases the same—the result, whatever it may be, must be accepted as surgically satisfactory for that case.
W. S. Forbes, Prof. Anat. Jeff. Med. Col, Surg. Prot. Episcop. Hosp., Phila., Pa.	1. The long axis and anterior surface of the inferior fragment should be in perfect accord and continuous with the long axis and anterior surface of the superior fragment. 2. The bond of union should have its transverse diameter but little, if any, in excess of the transverse diameter of the femur above and below the seat of fracture. 3. There should be but little, if any, shortening of the bone *several years after fracture* and its more skilful treatment. 4. The soft parts of the extremity should be free from scars and marks of the apparatus used in the treatment.	2. This fact would show, for the most part, that a good original adjustment of the fragments had been made by the surgeon, and that he had gently but firmly held the fragments in the proper position during the process of treatment, and that consequently there had been but little irritation of the parts. 3. I have so often found some little shortening that could not be attributed to difference in the length of the two femurs, which has been so often noticed in persons who never had a fracture, that my clinical experience leads me to think that, for the most part, some shortening usually follows a fracture, even a simple one, of the femur. I believe the shortening to be the result of the angular projection on the proximal surfaces of the fragment, and the shortening of the bond of union under the pressure of the superincumbent weight in early going about before solidity takes place.
J. D. Rushmore, Prof. Surg. Long Island Col. Hosp., Brooklyn, N. Y.	If the ordinary function of the limb has been restored, even with some deformity and moderate shortening, if the patient is able to use the limb for walking.	In cases in which the deformity is noticeable by the use of tights, and interferes with previous occupation, or necessitates a change, a moderate deformity might constitute an unsatisfactory result.
A. T. Cabot, Surg. Mass. Gen. Hosp., Boston.	In children under fourteen full length ought to be obtained; in patients over that age any result which gives from one-half to three-quarters of an inch shortening is to be looked upon as satisfactory.	In measuring the leg for shortening it is to be remembered that the legs are not always even in length in the first place, and a fracture of a shorter leg might give an apparently greater shortening than was real. The more muscular the leg the greater the chance of shortening due to contraction of the muscles and the slipping of the fragments.
DeF. Willard, Prof. Orthoped. Surg. Univ. of Pa., Phila.	When the shortening is less than half an inch, the foot and lower limb are in good position, and the restoration of function is complete.	I consider that a certain degree of loss of the structure by absorption of the two fractured ends is almost universal.
J. H. Brinton, Prof. Pract. Surg. and Clin. Surg. Jeff. Med. Col., Phila.	Any result is satisfactory in which the shortening does not exceed three-quarters of an inch, and the proper relations of the axis of the limb are maintained.	
J. E. Mears, Dem. Surg. Jeff. Med. Col., Phila.	Union with shortening of the limb from one-half to three-quarters of an inch.	
J. A. Comingor, Prof. Orthopedic and Clin. Surg. Central Col. Phys. and Surg., Indianapolis.	The fewest number of fractures of the shaft result in full length of limb; my cases have always fallen a little short; the average is about half an inch.	I have measured many cases of my own and others, and they were invariably a little short. I think it barely possible to obtain full length in oblique fracture. The method used by me is the plaster-of-Paris; its application has been made within a few hours or a day or two.
H. H. Mudd, Prof. Surg. Anat. and Clin. Surg. St. Louis Med. Col., St. Louis.	We should obtain union with the femur of normal length; the thickening at the point of fracture should be moderate in degree, not enough to interfere with the function of the leg, or to produce deformity.	The function of the limb should be practically perfect.

NAME OF SURGEON.	OPINION.	REMARKS.
L. McL. Tiffany, Prof. Surg. Univ. Md., Baltimore, Md.	1. Functionally the united femur should be as capable, as a weight-carrier and as a lever, as before the break. 2. Anatomically we do not consider rotatory or angular deformity. 3. Shortening is included in a satisfactory result.	1. The presence of persistent pain implies something more than a simple fracture; function is to be tested *months* after union is firm. 2. Practically it is found that the slight angular distortion not so unusual in the upper portion of the shaft does not impair function. In childhood there is a tendency to the correction of angular deformity. 3. Distinction is to be made between fracture occurring before and after the growth of the individual has been attained; prior to that period the shaft appears to grow (lengthen) more rapidly during a certain time than does the unbroken femur; hence shortening is comparatively less than in adult life. I do not remember having seen a museum specimen of adult femur united after fracture without shortening. Measurements to determine shortening after fracture are unsatisfactory owing (*a*) to physical difficulties, and (*b*) to the natural differences in the limbs.
S. Marks, Surg. St. Mary's Hosp., Milwaukee, Wis.	Taking into consideration all oblique, simple fractures of the femur in adults, an average of from one-half to three-quarters of an inch shortening.	Much depends upon the obliquity of the fracture and its location.
T. G. Morton, Surg. Pa. Hosp., Phila., Pa.	A moderate degree of shortening, say half an inch, more or less.	In most cases the line of fracture determines the shortening, which may be unavoidable and considerable; in transverse or partially transverse fractures little or no shortening is likely; in oblique or comminuted fractures more or less shortening will ensue, according to circumstances. Many other factors are liable to influence deformity, so that each case must be judged according to the nature of the injury. Asymmetry of the lower limbs is now recognized as the rule and not the exception, and, therefore, measurements can really have no certain practical value.
M. H. Richardson, Surg. Mass. General Hosp., Boston, Mass.	A straight limb with a shortening of less than an inch.	I would consider the result satisfactory it the patient could walk without a limp, and if there was neither pain nor disability.
T. F. Prewitt, Prof. Prin. and Prac. Surg. and Clin. Surg. Mo. Med. Col., St. Louis, Mo.	A shortening not exceeding a half or three-quarters of an inch.	
J. E. Owens, Prof. Surg. Anat. and Op. Surg. Chicago Med. Col., Chicago, Ill.	When the shortening does not exceed an inch and a half, and there is no unnatural bowing or angularity at the seat of fracture.	When the shortening exceeds an inch and a half there is some particular reason for it, such as inability to bear extension or the pressure of coaptation splints, or undue restlessness from confinement, or tampering with the dressings, or delayed union, or disobedience to the doctor's rules and failure to follow his advice, or a faulty method of treatment, or inefficiency in the management of a good method.
E. H. Bradford, Surg. Boston City Hosp., Boston, Mass.	In adults I should hope for no greater shortening than half an inch.	This, however, is a general statement, and will necessarily vary with the nature of the fracture, whether transverse or oblique, or in what portion of the shaft the fracture should occur.
E. M. Moore, Surg. St. Mary's Hosp., Rochester, N. Y.	In teaching I have taken the position that a shortening of one inch was allowable. Few persons are rendered lame with this relation between the two limbs after the sensibility of the new tissue has passed away. The attempt to prevent any diminution of the length of the limb is painful and sometimes prevents union, so that for a long time I have regarded a shortening of half an inch as a result of typical excellence, assuring contact and preventing lameness.	The question of a satisfactory result, independent of union, resolves itself into a consideration of the amount of shortening and deformity from an improper line between the two fragments and the proper position of the foot. The most obvious deformity is clearly that arising from the shortening of the limb. If not treated at all, this will vary from two to four inches, seldom less and seldom more. The deformity produced by the passing of the fragments is greater very much in proportion to the shortening; when the fragments overlap so far that the whole diameter of the bone is applied to that of its fellow, a huge tumor is apt to result, increased by the exudates. Moreover, a bending of the limb is likely to result when the shortening is marked, especially when the fracture is at the juncture of the upper and middle thirds. Transverse fracture is an idealism; practically it does not occur; it is only approximated. When a shortening of only half an inch exists there is a slight deflection from a straight line, which becomes essentially corrected by absorption of the broken fragments. I make no exception when the fracture is greatest below the lesser trochanter; when treated properly there should be scarcely the half-inch shortening allowable in the middle of the shaft.

If, in an adult, a fracture is followed by a change in the lengths of the legs there may be a temporary limp, due to the failure of the patient at once to adjust the pelvis and spine to this new condition. But in a vast proportion of cases the limp gradually disappears, or, if it becomes permanent, the result is due to the careless habits of the patient. This fact was strikingly illustrated at one of the military hospitals during the late war. This hospital became the rendezvous of soldiers who had recovered from crippling injuries of the lower extremities. It was noticed by the surgeons that there was a striking difference in the degree of lameness or limping among the men having the same degree of disability, and that some men with shortening of one leg to the extent of one-fourth of an inch had a much greater limp than others with from three-fourths of an inch to an inch of shortening. An attempt was made to overcome this defect by forming a company, and placing the men under the

drill of an officer of the regular army, with instructions to prevent limping in their exercise. The result was surprising. The limping gait quickly disappeared, even in those suffering from the greatest degree of shortening and deformity. This experiment proved that lameness or limping is not a reliable test of impairment of function, and should have only a relative value in an estimation of results.

We must conclude that lameness should be regarded as a proof of an unsatisfactory result only when it is due to a degree of shortening that renders a limp a necessity, and cannot be overcome by the efforts of the patient, but requires the aid of artificial appliances. We can find no better guide to determine the degree of shortening compatible with a useful limb, so far as lameness is concerned, than by referring to the standard that is furnished us in the discrepancy in the lengths of limbs that Nature has established. As has been stated, the most accurate measurements of healthy persons give an average difference in the lengths of the legs of about one-half an inch. But this difference may amount to one inch (or even more) in perfectly healthy and well-formed limbs. We may justly conclude, therefore, that a shortening of one-half an inch as the final issue of treatment of a fracture of the thigh, and after a proper use of the limb, gives a perfectly natural relation between the two limbs, and hence is an ideal result. We may conclude further, that if the shortening, after use, amounts to one inch, the result is still satisfactory, for this relation of the limbs as to length is still in accordance with the natural law of conformation. These measurements, it should be stated, are of the length of the entire leg, and not of the thigh only.

6. *Restoration of function.* The function of the lower limb is that of locomotion, with power to sustain whatever superincumbent weight is necessarily imposed by Nature or art. Essential to this function is strength of the femur at the seat of fracture, free and unimpeded action of the muscles, and proper motion of the knee-joint. The determination of the degree of restoration of function cannot be made until a suitable time has elapsed after the treatment has been suspended; for the recovery of the free action of the muscles and of the knee-joint requires persistent use of the limb for a variable period, depending much upon the age of the patient and the severity of the injuries inflicted when the fracture occurred.

We should fix upon one year after treatment has been discontinued and the patient has begun to use the limb as a reasonable period before a final judgment can be formed as to the completeness of restoration of function. If at the close of that period the patient has no other disability than the lameness, within the limits of shortening already given, the result should be considered satisfactory.

7. *Conditional results.* There is a class of cases in which our estimate of results must be based upon a careful study of the special circumstances connected with the treatment of each case. Results widely different from those already given may and must be regarded as satisfactory in these cases, when we give proper consideration to the conditions under which the treatment is necessarily pursued. The treatment may have been conducted under circumstances in which it was impossible to secure proper apparatus, or the injury may have involved other parts so as to prevent the patient from taking the necessary position, or the patient may have suffered from delirium or other disturbing malady. These cases must be regarded as exceptional; each one is to be decided according to its special features; and they need no further notice in this report than simple recognition.

Your committee respectfully submit the following conclusions, which they believe are in accord with scientific investigations, and which embody the experience and the opinions of the members of the Association, as far as they have been communicated to the committee.

CONCLUSIONS.—A satisfactory result has been obtained in the treatment of fracture of the shaft of the femur when—

1. *Firm bony union exists.*

2. *The long axis of the lower fragment is either directly continuous with that of the upper fragment or the axes are on nearly parallel lines, thus preventing angular deformity.*

3. *The anterior surface of the lower fragment maintains nearly its normal relation to the plane of the upper fragment, thus preventing undue deviation of the foot from its normal position.*

4. *The length of the limb is either exactly equal to that of its fellow, or the degree of shortening falls within the limits found to exist in 90 per cent. of healthy limbs, viz., from one-eighth of an inch to one inch.*

5. *Lameness, if present, is not due to more than one inch of shortening.*

6. *The conditions attending the treatment prevent other results than those obtained.*

THE CONDITION AND PROSPECTS OF THE LIBRARY OF THE SURGEON-GENERAL'S OFFICE, AND ITS INDEX-CATALOGUE.[1]

BY JOHN S. BILLINGS, M.D.,
SURGEON, UNITED STATES ARMY.

OF late years those physicians in this country who make use of medical literature in connection with

[1] Read before the Association of American Physicians, Washington, Friday, September 25, 1891.

their investigations or writings, have, for the most part, become acquainted with the resources of the "Library of the Surgeon-General's Office," as it is officially designated, and many of them are much interested in its progress and prospects. I am often asked how the collection is progressing, how near it is to completion, what it is most in need of, when the *Index-Catalogue* will be done, whether it will be followed by a supplement, whether there is danger that the work of the Library may be checked in the future through changes in administration, and so on.

These manifestations of interest are, of course, very gratifying, and when the Chairman of your Program Committee demanded a ten-minute paper from me on this occasion it occurred to me that I would try to answer some of the foregoing questions, so far as I am able to do so.

The present condition of the Library is fairly satisfactory. It now contains 102,000 volumes and 152,000 pamphlets, counting as pamphlets all octavos and smaller sizes having less than 100 pages, and all quartos of less than 50 pages. During the last five years, *i. e.*, from July 1, 1886, to June 30, 1891, the additions to it have included 25,237 volumes and 55,900 pamphlets, or an average of 5000 volumes and 11,000 pamphlets yearly. Of this annual increase, about 2000 volumes and 4000 pamphlets have been of new or current literature, and the remainder have been publications of previous years or centuries. About one-fifth of these accessions, of both new and old literature, have been presented; the remainder have been purchased. So far as mere size goes, it is the largest collection of medical literature in the world, and for the last five years has been increasing more rapidly than any other similar library containing 25,000 volumes and upward. It is especially rich in medical periodicals and Transactions of societies, of which classes it now contains about 34,350 volumes. The American, English, French, and German literature in all branches of medicine that has appeared during the present century is very fully represented, and over 90 per cent. of all the medical literature of the world for the last ten years is in the library. The whole is conveniently arranged in a fire-proof building, and is catalogued.

So much for the favorable side of the situation; now for a statement of some of the principal defects and deficiencies. Of medical incunabula, it contains 140 volumes, or about one-eighth of the medical works published prior to 1500. Of the published works of the ancient Greek, Roman, Arabian, and Hebrew medical authors, it has one or more editions of nearly all, but these editions are not in every instance the best. Of the early Spanish and Portuguese medical literature, it has almost nothing; of French medical works of the sixteenth century but little; of French medical theses prior to 1800, very few. Of the English, French, and German medical books of the 16th, 17th, and 18th centuries that are of any importance historically or practically, it has about 75 per cent.; of the Italian, about 50 per cent.; and of the Spanish, about 25 per cent. In its periodical literature it is especially deficient in the Spanish and Italian prior to about 1850, in the French prior to 1780, and in the Russian prior to 1860. If I could add to it about ten thousand volumes of my own selection, it would, I think, contain at least one edition of every medical work of any practical use or importance that has ever been published, although it would still not possess some fifty thousand pamphlets and theses, each of which might be of some historical interest.

These deficiencies in the Library are being gradually supplied, but the acquisition of the older books and pamphlets that are still wanted is becoming every year a slower, more difficult, and more costly process. This is due to the fact that the books still wanted are many of them rare, and only appear in the market at intervals of from five to fifty years; to the fact that the number of competitors for such books is increasing, and, above all, to the fact that the expenditure of time required for the examination of the numerous catalogues and lists received at the Library in order to select those books that are still wanted is becoming very great in proportion to the results obtained. To check off a catalogue of a thousand medical books with the result of finding about four that are really desirable, a dozen that may be accepted as filling gaps, and about twenty small theses that are not in the collection, involves an amount of clerical work that costs as much as, if not more than, the books thus obtained. In one sense it is true that this is a satisfactory condition for a library to be in, but, nevertheless, the loss of time spent in such checking is to be regretted.

With regard to current medical literature, the amount increases each year, but the rate of increase is becoming slower. Comparing the period of 1890 with that of 1880, we find that the number of medical writers increased from 11,600 to about 14,200, or a little over 22 per cent. There were published in 1890 about 2000 volumes and 4000 theses, pamphlets, and reports in medical literature. Of the volumes, about 930, or not quite half, were furnished by medical journals and Transactions, as against 864 of the same kind in 1880—being an increase of about 7½ per cent. Excluding the journals, Transactions, and theses, the number of medical books and pamphlets published in 1890 was about 1850 as against 1600 in 1880—being an increase of about 15½ per cent. This indicates that the increase in the number of medical writers, and in the quantity of medical literature that they have pro-

duced, has not been proportionally as great as the increase in population and in the number of physicians in civilized countries during the decade, which confirms the statement that I made ten years ago, that the rate of increase is becoming smaller.

In the United States the proportion of periodical literature to the whole is much greater than it is in other countries—for in 1890 it produced about 250 volumes of medical periodicals, 60 volumes of new medical books, 20 volumes of later editions, and 28 volumes of reprints of English books and Transactions; while France produced about 160 volumes of medical periodicals, 250 volumes of new medical books, 20 volumes of later editions, and 15 volumes of Transactions; Great Britain about 85 volumes of periodicals, 140 new books, 45 volumes of later editions, and 12 volumes of Transactions; and Germany about 175 volumes of medical periodicals, 175 volumes of new books, 80 volumes of later editions, and a dozen volumes of Transactions. All this is exclusive of pamphlets. Of course, quantity in medical literature has no definite relations with quality or value, but I am speaking now merely with reference to the number of separate pieces that are to be obtained, catalogued, and cared for, and you will see that, including journals, Transactions, reports, books, pamphlets, reprints, and theses, we shall have at least 6000 new pieces to provide for this year. The indexing of articles in journals and Transactions will in addition involve the writing and classifying of about 25,000 titles.

Of the *Index-Catalogue* of the Library, twelve volumes have now been printed—carrying the work to S. The thirteenth volume is nearly ready for the press, and the manuscript for the rest of the work—at least two volumes more—has been prepared, but has not yet been finally corrected and arranged. As we can print but one volume a year, it is evident that during the twelve years that have elapsed since the publication was commenced a large number of titles of books and articles received too late to be placed in their proper places must have accumulated, and this accumulation becomes more rapid every year as we get further down the alphabet in the course of printing the work. At present the number of unprinted titles thus accumulated under authors and subjects down to S, probably amounts to 70,000 author- and 240,000 subject-titles, the latter of course including the titles of indexed journal articles. If these were now printed they would make about four volumes of the size of the volumes of the *Index-Catalogue*, and three years hence, when this first series of the *Catalogue* is finished, there will probably be material on hand sufficient to form at least five volumes of a supplement or second series, which will no doubt expand into six volumes by the time the printing of this second series is finished—that is, if the Library continues to increase as it has done for the last five years.

The twelve volumes of the *Index-Catalogue* already printed contain 137,578 author-titles covering 66,855 volumes and 120,000 pamphlets, 522,092 subject-titles covering 128,284 titles of books and pamphlets, and 393,808 articles in journals and Transactions. The titles of articles in journals and Transactions are printed only under subject-headings, those of books and separately-paged pamphlets and reprints are printed twice—once under the name of the author and once under the name of the subject. All the cards for journal articles have been preserved, and when the printing of the *Catalogue* is completed, it is proposed to assort these according to authors, so as to bring under each man's name the title of all the articles he has written that have been indexed. Whether this will ever be printed I do not know. The chief errors in the *Index-Catalogue* are those of omission. About fifty serious errors in the first twelve volumes have thus far been detected, but the main defect is the failure to include under the proper subject-headings some books and journal articles that are in the collection. We have gained experience as the work has progressed, and the later volumes seem to be more full and accurate than the first.

Of main and subordinate subject-headings the *Index-Catalogue*, as a whole, contains about 20,000, and in placing the proper headings on the subject-cards to indicate where each is to be placed, it is necessary, in order to secure good results, that the person doing this shall not only remember the general scheme of classification, but the details of between four and five thousand of the subject-headings used. If he makes an error, the card goes to the wrong place and is liable to be omitted in printing; but, in the long run, it is sure to be discovered and placed where it belongs.

In connection with the *Index-Catalogue* a few words with regard to the *Index Medicus* may be of interest. This, as you know, is in the main a record of the titles of new books and articles in periodicals received at the Library, to which are added the titles of a few books advertised as published but not yet received. It is not published by the Government, but by Mr. George S. Davis, of Detroit, who pays all expenses connected with it, and is entitled to the thanks of all who use it for his public spirit and enterprise in maintaining its existence, since the amount received by him for subscriptions barely meets the cost of its publication. At present 482 subscriptions are made for this periodical, of which 90 come from the U. S. Army Medical Department, 224 from the rest of the United States, and 168 from other countries. Of the subscriptions from foreign countries, Australia sends 5; Belgium, 2;

Brazil, 1; Canada, 2; England, 41; France, 26; Germany and Austro-Hungary, 63; India, 1; Ireland, 2; Italy, 1; Mexico, 1; Russia, 9; Scotland, 9; Sweden, 2; and Switzerland, 2. Of the home subscribers, California furnished 8; Colorado, 1; Connecticut, 3; District of Columbia, 13; Georgia, 2; Illinois, 9; Kentucky, 1; Louisiana, 3; Maine, 2; Maryland, 10; Massachusetts, 31; Michigan, 8; Missouri, 4; Nebraska, 1; New Jersey, 5; New York, 69; Ohio, 8; Pennsylvania, 33; Rhode Island, 4; South Carolina, 1; Tennessee, 1; Vermont, 1; Virginia, 1; Wisconsin, 4. For the large cities, the figures are, New York, 50; Philadelphia, 32; Boston, 24; Baltimore, 10; Cincinnati, 7; Chicago, 6; San Francisco, 4; Detroit, 4; and St. Louis, 3.

This is the last of the statistics of the Library and matters connected with it which will be inflicted on you at this time. The figures themselves may be dull, but some interesting, and even amusing, conclusions may be drawn from them, which I leave for you to do.

In conclusion, I may say that the future prospects of the Library are excellent. It is not dependent on the skill or energy or good-will of any one man; it is becoming more and more known to, and more and more used by, the members of the medical profession, and so long as they are interested in it, the necessary appropriations will be made and the skilled force employed to increase, preserve, and catalogue it. The service rendered by a number of those employed in the Library is not a mere matter of money—they are deeply interested in their work and proud of the results, and they can and will carry it on and instruct others who will come after them and do likewise. They have to handle much rubbish, for the proportion of what is both new and true is not much greater in medicine than it is in theology, but in a great national collection this is unavoidable, and the best they can do is to make a first rough assortment, and then make the whole accessible to those who wish to use it. There is no doubt that the publication of the *Index-Catalogue* will be completed, and that a supplement will speedily follow.

Just at present the most unsatisfactory feature about the Library is the fact that many of its books and journals are not fully available for use owing to the fact that we cannot get them bound. Under existing laws all the binding of the Library must be done at the Government Printing-office, which has not room or men sufficient to do the work required for the different departments of the Government and for members of Congress. The result is that the Library now has about 10,000 unbound volumes, and this number is increasing every year. When a journal is sent to be bound it may be six months or more before it is returned. With the erection of additional accommodations for the Government Printing-office it is to be hoped that this evil will in time be abated; but under the present system there will always be more or less delay in making recent books and periodicals available for use. The most effectual remedy would be a change in the law, whereby the Library could have its own binding done in its own building and under its own control.

CLINICAL MEMORANDUM.

ARSENITE OF COPPER IN DIARRHEA.

By C. S. STEWART, M.D.,
OF SCRANTON, MISS.

My attention having been called to the efficacy of arsenite of copper in all forms of bowel trouble, I have managed to find enough cases for testing its virtues, and have come to the conclusion that although its healing qualities are overrated, it is still very useful in subacute or chronic forms of diarrhea, rather than in the earlier stages. The following cases will illustrate:

Case I.—Mrs. H., aged thirty-five years, had diarrhea with varying degrees of severity for two years, and had tried changes of treatment and climate to no purpose. As she had previously a malarial attack, I used quinine in the beginning of the treatment, but the principal remedy was arsenite of copper, the one-hundredth of a grain given each day. Improvement was noticeable at once and in six weeks recovery was complete.

Case II.—H. R., two years old, began with an attack of summer diarrhea, and after a week improved slowly under the usual remedies recommended for such cases, but shortly afterward suffered a relapse, and the condition was fully as bad as before. Then all treatment was stopped, and arsenite of copper, the one-hundredth of a grain given during the twenty-four hours, was continued alone, and was followed by speedy and permanent improvement.

Case III.—M. V. C., aged forty years, was a steady drinker and subject to attacks of diarrhea. The present attack began as a "bilious spell," but the bowel-condition grew steadily worse, and despite nearly every remedy offered for such conditions, there was a continual decline, followed by a slow improvement after a couple of weeks. The patient then took a trip to Healing Springs, Ala., but returned in a worse condition than before, with eight or ten stools each day, a considerable elevation of temperature, and the tongue looking like a piece of raw beef, the stomach irritable, and nausea easily provoked. Since hardly anything could be given, arsenite of copper, because of its tastelessness, was begun, and its administration was followed by a subsidence of the bad symptoms and a speedy convalescence.

The physiological action of this remedy has not been sufficiently explained, but it evidently exerts both a tonic and astringent effect, correcting the disorder by restoring a healthy condition of the bowel, and leaving the patient well. The drug is soluble in water, and perfectly tasteless, and, especially with children, its range of usefulness is great. Further experience will, no doubt, determine the limits of its usefulness.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment. When necessary to elucidate the text, illustrations will be provided without cost to the author.

SATURDAY, SEPTEMBER 26, 1891.

THE CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS.

WHEN one thinks of such professional gatherings as that which has just been held at Washington, the question arises why so many busy men should steal from their needed rest the time to prepare their many papers, to attend the meetings, and at much and varied expense leave home and practice at a particularly busy season. The answer will be found to lie deeper than would at first appear. The desire to obtain honor in the eyes of one's fellows, the ideals of personal ambition, sociability, etc., are hardly ever wanting in the actions of any large body of men, but in none are they more subordinate than in the profession of medicine. Such a ferment of new thought and scientific zeal pervades its members that selfish aims are forgotten in the enthusiasm of new discovery and therapeutic power. It is indeed a marvellous thing—this of a splendid army of men seeking with ardor its own professional undoing. However far we may be from an absolute prophylaxis and cure of all disease, the fact remains that every true physician is devoted to that ideal—seeking to make his own office a useless one. It is precisely this aspect of our professional life that can never fail to elicit the admiration of a discriminating and intelligent public sentiment. These men do not meet to discuss how they can best obtain the plums of insurance fees, the greatest commercial and legislative advantage. The keynote and rallying cry of every speaker has been like that of the old Roman CATO, with disease as our Carthage.

As we go to press the great Congress at Washington is closing its sessions. It is as yet too early to pronounce any critical judgment as to the proceedings in detail or as a whole, but the tremendous vitality and earnestness of American medicine is manifest in the simple fact indicated by the summarizations of the official programs: There were announced more than 400 addresses, papers, and discussions. Besides the Americans present, there were at least nine invited guests from England, four from Scotland, three each from France and Germany, as well as others, all taking active part in the proceedings. But, of course, size and numbers do not count in such matters, unless at the same time quality dominates. In the current and coming numbers of THE NEWS, our readers will have an opportunity of judging for themselves as to the scientific value of the contributions. Extraordinary endeavors have been made to secure in advance, directly from the participants, either their original papers or their own authoritative abstracts. The promptness and willingness with which compliance has followed request will place every reader of THE NEWS under obligations to the members of the various societies. Author and reader have a mutual interest in a trustworthy report.

SOCIETY PROCEEDINGS.

CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS.

Second Triennial Meeting,
Held at Washington, September 22, 23, 24 and 25, 1891.

(Specially reported for THE MEDICAL NEWS.)

FIRST DAY—SEPTEMBER 22D.

THE Congress was called to order by the Chairman of the Executive Committee, DR. WILLIAM PEPPER, who introduced the President, DR. S. WEIR MITCHELL, of Philadelphia.

The first scientific matter brought before the Congress was a discussion on "Conditions Underlying the Infection of Wounds, Including a Discussion of Disinfection with Reference to Treatment of Wounds, of the Relation of Bacteria to Suppuration, of the Resistance of Tissues to the Multiplication of Bacteria, and of the Effect of Antiseptic Agents on Wounds."

The discussion was opened by the Referee, DR.

WILLIAM H. WELCH, of Baltimore. He said that the presence of certain kinds of bacteria as an essential condition of wound-infection is so well established that discussion of this point is not likely to arise. The comparatively simple conception that a wound to which bacteria gain access necessarily becomes infected has been greatly modified. The traumatic infections present their own peculiar problems. The doctrine of wound-infection involves the consideration of many varying and often complicated factors relating both to the agents of infection and to the individual exposed to the infection.

The subject was considered under the following heads: 1. What are the microörganisms concerned in the infection of wounds, and how do they act? 2. How are we to explain the great differences in the effects produced by pyogenic micrococci—their apparent harmlessness under some conditions, their fatal influence under others? 3. What are the ways by which bacteria gain access to the wound? 4. How often are bacteria to be found in wounds treated antiseptically or aseptically? what are the characters of these bacteria, and where do they come from? 5. What are the best means of surgical disinfection?

The observations as to the relative frequency of ordinary pyogenic staphylococci and streptococci are not altogether concordant. The yellow staphylococcus appears to be more common in furuncles and abscesses than the white staphylococcus.

Dr. Welch had found a white staphylococcus in small stitch-abscesses and minor grades of inflammatory disturbance, in wounds treated antiseptically and aseptically, which differs in certain particulars from the staphylococcus pyogenes albus. He suggested that it be called the staphylococcus epidermidis albus. The efforts to differentiate into distinct species the pathogenic streptococci have met with little success. The list of bacilli that may be concerned in suppurative and other inflammatory affections is much longer than was formerly supposed. The bacillus coli communis furnishes an illustration of the possible predisposition to infection afforded by intestinal lesions and of the much-disputed auto-infection. Of the suppurative inflammations examined bacteriologically with negative results, may be mentioned abscesses in which the bacteria were presumably dead, several cases of pyosalpinx and suppurating buboes, and some abscesses of the liver.

There is reason to suppose that the process of suppuration serves a useful purpose and is one of the most efficient weapons employed by Nature in combating invading microörganisms. Exactly how the abscess-formation checks the invasion of bacteria we do not know.

The quantity of a culture of the staphylococcus aureus required to produce suppuration is not the same for all tissues and all parts of the body. There are also variations in virulence of different cultures of the pyogenic cocci. As it is by their toxic products that the pyogenic bacteria do injury, it is not surprising to find that it makes a great difference in the result whether or not these bacteria enter the tissues already equipped with a reserve force of poisonous material or whether they must begin the fight unarmed. This matter of toxines is possibly of great importance in understanding the potentialities of the living agents of wound-infection. The differences in virulence found to exist between inflammatory exudates from various sources are much greater than those observed in the cultures of the corresponding bacteria on artificial media.

In regard to the conditions in or about a wound that favor the lodgment and development of pyogenic bacteria, it may be said that anything that interferes with the integrity of the living tissues in a wound is a predisposing cause of suppuration. Chemical irritants, such as carbolic acid and corrosive sublimate, favor the development of microöganisms. A solution of corrosive sublimate as weak as 1 : 2000 gives rise to a distinct line of superficial necrosis. We are not so well informed as to the influence exerted by blood in a wound. Most surgeons lay great stress on hemostasis in surgical operations, while others advise that in certain classes of cases the wound be permitted to fill with blood-clot. Is this a source of danger? Fresh blood-serum does not possess any such germicidal power over the pyogenic cocci as it does over typhoid and many other bacteria. The power of the living tissues to overcome a certain number of pyogenic bacteria is well recognized and the tendency of modern surgeons is to respect these tissues more and more, and not to destroy their vital capacities by the unnecessary application of strong chemical disinfectants, not to bruise them, not to make them too tense, not to strangle them, not to suffer in wounds the presence of spaces and foreign bodies that remove bacteria from the influence of the living fluids and tissues.

Of the various ways in which pathogenic bacteria gain access to wounds, that by contact with infected hands, instruments and other objects offers the greatest danger. The possibility of infection from the air cannot be ignored. Even in wounds treated aseptically or antiseptically it is not uncommon to find bacteria. The skin may have all sorts of bacteria upon it, but in addition it has its own distinctive bacteria. After the skin has been thoroughly washed and scrubbed, the prevailing organism will be found to be the white staphylococcus. This is often found in parts of the epidermis deeper than can be reached by any known means of skin-disinfection. We can now understand how, without any flaw in the antiseptic technique of the surgeon, this microörganism may be found present in wounds, and we have here an explanation of the frequent occurrence of stitch-abscesses, although the inference should not be drawn that the white staphylococcus is the only bacterium concerned in the production of these annoying complications. How much practical importance attaches to the demonstration of this coccus is not yet certain. The surgeon, with good technique, who does not bother himself about this coccus in the deeper layers of the skin, is not likely to be severely punished by the behavior of his wounds. Those who put in drainage-tubes and other extraneous substances will have to consider it. On the basis of researches on the bacteria of the skin, some surgeons have abandoned skin-sutures, the edges of the wound being brought together by subcutaneous sutures.

In regard to the methods of surgical antisepsis, it is said that the conditions for efficient chemical disinfection have been found to be far more complicated than was formerly supposed, and that wherever applicable the substitution of the simple and certain method of disinfection by heat is to be commended. For many pur-

poses in the operating-room chemical disinfectants still have their place, but their place is not in healthy wounds. Thorough scrubbing of the skin with soap and water, with a sterilized brush, removes many of the bacteria, but not all, and cannot be regarded as a satisfactory means of cutaneous disinfection. Corrosive sublimate accomplishes much less than is generally supposed. The best results obtained have been by a method in which a warm saturated solution of potassium permanganate, followed by a similar solution of oxalic acid, plays the principal disinfectant rôle. This is the procedure now adopted in the gynecological and surgical wards of the Johns Hopkins Hospital.

DR. ROSWELL PARK, of Buffalo, Co-referee, continued the discussion. The full text of his paper will appear in a future issue of *The American Journal of the Medical Sciences*.

He stated that all the sources of sepsis by no means concern the wound itself. The other principal sources of infection may be classified as follows:

1. Previous long-existent toxemia, as syphilis, diabetes, acetonemia, lithemia, alcoholism, malaria. 2. Previous anatomical changes that reduce vitality, as inherited diatheses, old age, amyloid change, chronic and acute nephritis. 3. Recent or acute toxemia, as uremia, typhoid, intestinal toxemia, stercoral toxemia. 4. Other acute conditions, as starvation, scurvy, anemia. 5. Conditions of environment, as bad hygienic surroundings. 6. Effect of anesthetics. 7. Effect of antiseptics.

Antiseptics may favor infection in more than one way. Mercurial and iodoform poisoning are not uncommon. When this is established the case becomes one of acute toxemia. The wounds may fail to unite and suppuration may occur. Again, the chemical reaction between the vital fluid and the antiseptic may cause a loss of the properties of the antiseptic agent, while the tissues on which it acts may have their constitution so changed as to favor rather than to resist infection. Investigations make it appear best to keep all antiseptic agents away from absolutely clean, fresh surfaces. The value of blood-serum as an antiseptic has been abundantly shown. This will be poured out in quantity sufficient to serve not only as a cohesive but as an antiseptic agent. The question here arises as to what is the best antiseptic. It would appear that for most purposes peroxide of hydrogen is the ideal antiseptic, as it not merely destroys living organisms but by oxidation of undesirable and infected material acts as a scavenger of the tissues. We have, however, yet to learn how to utilize to the fullest advantage the properties of blood-serum.

Direct infection may be of two varieties, self-infection or auto-infection, and contact-infection. The principal sources of contact-infection are as follows: 1. Skin and hair. 2. Instruments. 3. Sponges or their substitutes. 4. Suture materials. 5. The hands of the surgeon and his assistants. 6. Drainage material. 7. Dressing material. 8. Miscellaneous—*e.g.*, drops of perspiration, an unclean irrigator-nozzle, the nail-brush, the clothing of the operator or bystanders, etc.

The best plan of sterilizing the skin is shaving, followed for a day or two, if there is time, by the application of some antiseptic ointment. The skin should then be washed with sapo viridis of the German Pharmacopœia, containing 5 per cent. of lysol or hydro-naphthol. Then until the time of operation there should be worn a compress wet with some liquid, non-irritating antiseptic, such as creolin or lysol (5 per cent.), or hydro-naphthol in saturated cold aqueous solution. At the time of operation there should be a final scrubbing with hydro-naphthol soap, with shaving, and then the skin washed with equal parts of alcohol and ether, or alcohol and turpentine. When there is not time for this, thorough use of the nail-brush, the razor, and antiseptic soap, with subsequent use of alcohol and ether, must suffice.

Instruments are best prepared by dry sterilization, as this injures them less than other plans. In regard to sponges, there is nothing to be added to the well-known directions. It would seem better to use some cheap absorbent material, which after use could be thrown away. Silk is best sterilized by placing it in a test-tube, plugged and kept in a steam sterilizer for two periods, each of an hour. Silkworm-gut may be prepared by immersion for a few hours in a 1 per cent. aqueous solution of corrosive sublimate and then preserving in alcohol. Catgut is best prepared by immersion in benzine or ether to remove the fat. It is then dried, and soaked for one or two days in a 1 per cent. watery solution of corrosive sublimate, after which it is dried and transferred to oil of juniper-berries, and from this to strong alcohol containing 1 : 1000 of sublimate. In this, if desired, it can be boiled. It may be chromicized before being placed in the oil of juniper. The hands, even after having been in contact with septic matter, may be sterilized by the following method: Wash with soap and water, using the nail-brush; then wash the hands and arms with flour of mustard as though it were powdered soap; this will remove all odor; then wash with sapo viridis [G. P.], to which has been added 5 per cent. of lysol, creolin, or hydro-naphthol; then rinse and immerse in a deeply colored solution of potassium permanganate; the hands are finally rinsed and immersed in a solution of oxalic acid sufficiently strong to decolorize the skin in two or three minutes; the oxalic acid is rinsed off, and the hands may be considered aseptic. Drainage is probably required only in septic or infected cases.

After an ideal aseptic operation, only a sterilized and a protective dressing is required. In some cases there may be advantage in impregnating the dressing with some antiseptic.

Among miscellaneous sources of infection may be mentioned the use of an unguent applied to the skin to prevent the adhesion of dressings. Experiments have shown that ointments made with even 10 per cent. of resorcin or naphthalin, without the application of heat, contain bacteria. The same ointments, heated to the temperature of boiling water, seem to be sterile, and to suffer only from air-contamination.

Dr. Park presented the following conclusions:

1. A study of wound-infection and of the septic condition thereby produced is inseparable from a study of what constitutes immunity.

2. By a study of immunity is furnished the best clue to a due appreciation of the principles of asepsis.

3. The surgery of the future must aim to be aseptic, for, so far as recent cases are concerned, we have passed the merely antiseptic era.

4. Asepsis is to be achieved not alone by attention to the wound and the paraphernalia of operation, but by

the closest regard to the condition of the patient's organs and tissues.

5. Sepsis may arise from circumstances and conditions other than those pertaining to the wound itself, although hitherto practitioners have been too prone to scan solely this field when searching for its cause.

6. Sepsis and infection are combated in more than one way by natural agencies and by inherent properties of cells and fluids, totally aside from the measures that the surgeon institutes, and the wisest man is he who studies to take advantage of these vital activities rather than introduce new and conflicting elements from without.

7. A recognition of the power of chemotaxis possessed by organized and unorganized materials in such varying degree, can be utilized to great advantage as soon as it can be reasonably clearly defined.

8. A study of chemotactic activity appears to impress one with the truth of the phagocyte doctrine, which if substantiated will have an important bearing upon the principles as well as the practice of the surgery of the future.

9. The proteid material contained within cellular infectious organisms plays such a rôle both in causing chemotaxis as well as in poisoning the animal infected that we have reason to eagerly welcome all knowledge concerning it.

10. As fast as such proteid material can be isolated, we need among other things to study its effect upon the commonly used antiseptic agents.

11. We need to study much further the anti-toxic and bactericidal properties of human blood-serum, and the means by which we can avail ourselves of the same.

12. Some such classification of the various causes of lowered resistance to infection as that given, or of the causes of vulnerability or susceptibility, will certainly assist in a due appreciation thereof, and will often aid in so fortifying the patient that he may resist infection to which he would otherwise succumb.

13. The condition of enterosepsis, fecal toxemia, stercoral intoxication, or whatever it may be called, is certainly one that every practitioner has to fear and against which he should assiduously guard. It is not sufficiently generally recognized and combated.

14. A sub-form of this condition might justly be made and entitled gastrosepsis, comprising cases in which defective stomach digestion, often from dilatation, brings about a lithemic or other toxemic condition that favors infection.

15. Antiseptic agents in the past have worked a revolution in surgical practice and results. It is now time to know that they all have their disadvantages and to understand that strict asepsis will obviate the necessity of antiseptic applications.

16. The insurance of the aseptic character of such work necessitates the use of antiseptic agents of some kind upon everything that may directly or indirectly come in contact with wound-surfaces.

17. When this work is strictly aseptically performed, the use of drains, or further employment of antiseptics, is either an expression of mental uncertainty or of fear. It may be in the interest of humanity—undoubtedly it often is—but it is not attaining the ideal scientific work.

In the subsequent discussion, DR. ARTHUR T. CABOT, of Boston, referred to the debt that practical surgeons owed to the scientific workers. It is the knowledge of how to obtain aseptic wounds that has revolutionized surgery. As to the phagocytic action of the cells, and to the germicidal action of the blood-serum, the only question is, as to which of these processes is distinctly destructive. The bactericidal action of the blood-serum has been proved. These observations may serve to explain some of the phenomena in wound-fevers. It may be that in erysipelas, the irritation set up by the application of blisters, iodine, etc., may serve to limit the spread of the disease by the action of the blood-serum on the micrococci of the disease.

In the treatment of wounds it is desirable to avoid placing animal sutures in the wound. It is better to close all spaces in the wound by pressure. Culture-experiments have demonstrated that when, prior to the operation, the skin is free from organisms, at the close of the operation their presence may be detected, showing that bacteria had been sown on the wound by the air, or otherwise. If necrotic tissue or animal sutures be present, they may constitute a nidus for the development of the bacteria.

MR. THOMAS BRYANT, of London, said that if bacteria are the seed, we must remember that the soil is not of less importance. If the soil is not suitable for the growth of the seed, it will not sow. Except in a case of urgency, no surgeon would operate on a patient until the subject had been prepared for operation. In order to prevent the entrance of germs, irrigation is of service. For this purpose, iodine-water, made by adding a few drops of the tincture or solution of iodine to water, is a most valuable solution. This may be made of a light-cherry hue for clean wounds, and of a dark-cherry for dirty wounds. It also acts as a styptic. As a dressing, he uses wood-wool. The wound is dusted with iodol one part to from one to five parts of boric acid. In every operation there is a certain amount of molecular death, and drainage is required for thirty-six hours. For bringing the deeper parts of the wound in contact, pressure is better than deep sutures.

DR. HAROLD C. ERNST, of Boston, said that while it is true that nearly all forms of suppuration are attended by bacteria, yet it has been shown that a process corresponding to suppuration can be produced without the action of bacteria. The products of this suppuration, however, do not give rise to a like process when introduced into other animals. It has been shown that some of the agents used to destroy bacteria really favor their growth by diminishing the chemotactic power of the surrounding tissue-cells. Notwithstanding that laboratory experiments show the possible occurrence of chemical suppuration, it still remains to be demonstrated that the infection of wounds, as seen in practice, occurs without the influence of bacterial activity. The most important lessons taught by investigations on this subject are those that warn us that our pupilage is not yet over, and that we are but entering upon the first stage of our knowledge of the processes under discussion.

MR. JOHN CHIENE, of Edinburgh, said that he had assisted Professor Lister during the whole of his time in Edinburgh. The longer he lived the more he believed in the work of Lister and the impress that he had made on surgery. He considered bacteriological investiga-

tion as of the greatest importance, for on it the surgeon must depend in his daily work. Lister long ago spoke of the antiseptic value of the blood-clot, but John Hunter had long before pointed out the same thing. The spray is of great service. The term "integrity of the tissues" had been used, but John Hunter had also laid stress on the "vitality of tissues," which he defined as "the power of the tissues to resist putrefaction." The best results will be attained by not only improving the soil, but also by destroying the plant.

DR. ARPAD G. GERSTER, of New York, considered the many sources of contact-infection, and referred especially to infection the result of bad habits on the part of the surgeon. The surgeon may carry out all the details of aseptic and antiseptic treatment, and yet nullify all by rubbing his nose, his hair, or his face, or by placing the knife in his mouth that he might use his hand. An important point in the prevention of infection is clean dissection with the knife, without tearing or bruising the tissues. Irrigation and drainage could be eliminated only when the surgeon was absolutely certain of his asepsis; it is dangerous for the general practitioner to discard drainage. If he is not certain of his asepsis, he should cling to the older methods, and from these he may ascend to the highest degree of skill, when he can work with real asepsis.

SECOND DAY—SEPTEMBER 23D.

DR. P. S. CONNER, of Cincinnati, Referee, read a paper on "The Late Manifestations of Syphilis," which is to appear in a subsequent number of THE MEDICAL NEWS.

He stated that the early manifestations of syphilis occasioned little concern; but it can never be known in advance what the sequelæ will be. The victims of inherited syphilis suffer in greater degree and frequency from late lesions than do the cases of acquired syphilis. There is no sharply-defined line of separation between the early and the late symptoms. Speaking in a general way, the late lesions are neoplastic; the early lesions rarely so. The late lesions are not communicable. Their development is usually insidious. The bones and the nervous system are most commonly invaded. Extensively destructive and deforming bone-inflammations are almost exclusively confined to the head and the nasal regions. The explanation depends upon the exposed position of the bones, their thinness, the abundance of small vessels, and the intimate fusion of mucous membrane and periosteum. Chronic bone-disease and joint-disease in children, adolescents, and young adults are mostly tuberculous; in not a few cases, however, they are syphilitic. The most frequent and the most dangerous lesions are those of the nervous system. Affections of motion, sensation, and intellection are common in the order given. Hysteria may imitate syphilis. It is infrequent in men, while brain-syphilis is rare in women. Special lesions are not common. Exostoses may form; neoplasms may develop. There may be pain and palsy distributed in accordance with the site of the lesion. Most ataxics have had syphilis, but tabes is not of gummatous origin; nor can the sclerosis be regarded as the result of the diffused formation of fibrous tissue so often found in the cerebro-spinal axis. Antisyphilitic treatment generally fails to cure or even to retard the evolution of the symptoms.

Preëxisting tuberculosis aggravates the diagnosis of syphilis. Syphilis is not likely to be inoculated in a person with carcinoma. Carcinoma, however, not rarely invades an area in which there has long been specific thickening and induration, as in the chronic leucomata of the tongue. Occasionally a gumma becomes carcinomatous. When the disease is latent the wounds of syphilitics, as a rule, heal as promptly as in other cases; but when the specific lesions are in process of evolution, repair may be interfered with. Many cases of aneurism in persons under forty years of age depend upon syphilis. The mortality-rate from acquired syphilis is almost *nil*. Inherited syphilis is a grave disease. Four-fifths of the pregnancies of congenital syphilitics terminate prematurely.

DR. ABNER POST, of Boston, Co-referee, followed. He considered syphilis from the standpoint of the clinician and student, and not from that of the pathologist. He called especial attention to what is known as late hereditary syphilis, in which the disease is inherited, although the symptoms first appear after a lapse of years, with symptoms corresponding to the tertiary symptoms of acquired syphilis. The later forms of acquired syphilis are not necessarily a part of the case. The so-called late lesions occur much earlier in the history of the disease than is ordinarily believed. After the third year the chances of recurrence grow steadily less. As a preventive of late symptoms, early treatment by mercurials holds first place, but by no method can a cure be assured—that is, absolute immunity from subsequent outbreaks.

Induration and enlargement of the lymphatic glands is one of the common symptoms of early syphilis. In late hereditary syphilis the lymphatic system plays a conspicuous part.

Cutaneous lesions are second in frequency to the lesions of the nervous system in late acquired disease. Syphilis differs from tuberculosis in manifesting a preference for the long bones and their shafts, while tuberculosis attacks by preference such bones as those of the wrist and ankle.

Diseases of the joints are at times undoubtedly the result of syphilis. It is fairly well-established that serious syphilitic lesions of the gastro-intestinal tract may take place. As one of the possible causes of disease of the ileo-cecal valve, syphilis must be given a certain amount of consideration. Diseases of the nervous system dependent upon congenital syphilis constitute a large field practically unexplored.

Little importance can be attached to a negative history. Many syphilitics cannot know of the existence of the disease.

The prognosis must be a matter of special consideration. It is the persistence of the damage and not the specific lesions that cause the persistence of the symptoms. There is something to be deduced in the matter of treatment. Anti-syphilitic treatment has great power over the active processes of late lesions, but is powerless to restore the tissue already destroyed. The attempt to destroy a syphilitic tertiary sore is, in general, futile. The late lesions of inherited syphilis are as readily controlled as those of the acquired disease. Large quantities of iodides may be administered. In regard to treatment of retrospective disease, too much value must not be placed upon this element in doubtful

cases, for mercurials and iodides do have some influence upon tuberculosis.

The study of syphilitic phenomena is a necessity of medical progress. The possibility of syphilis renders uncertain the diagnosis of tuberculosis and carcinoma and other forms of malignant disease. What is needed are careful clinical studies, hospitals especially devoted to syphilis, and the study of syphilis made obligatory.

The subject was further discussed by Dr. Robert T. Edes, of Washington, and Dr. James Nevins Hyde, of Chicago.

In the evening, the President of the Congress, Dr. S. Weir Mitchell, of Philadelphia, delivered an address entitled "The History of Instrumental Precision in Medicine." He considered specialism in medicine, its virtues, and its shortcomings. He gratefully admitted the value of specialism, but he also cautioned against the perils to which the subdivisions of labor that it entailed exposed the profession of medicine. Dr. Mitchell paid a tribute to the growing usefulness of the Weather Bureau, especially in the study of meteorologic and climatologic influences upon disease and the therapeutics of disease. He made brief reference to the growing social changes by which woman is being and is about to be influenced by a masculine education, and the acceptance on her part of male standards of work and capacity. He then took up the advances that have been made in the methods of observation in disease, and confined himself especially to the earlier efforts to obtain accuracy by instruments in the study of the pulse, respiration, and temperature. Finally, Dr. Mitchell successively reviewed the stages through which the thermometer passed before it attained its present perfection, and the gradations by which the clinical significance of a study of the pulse was reached.

Third Day—September 24th.

Dr. A. L. Loomis, of New York, opened the discussion on "Fibroid Processes (Chronic Interstitial Inflammation, Scleroses); their Pathology and Etiology, with Especial Reference to the Influence of Diathesis and Heredity."

He held that fibroid processes cannot be considered as degenerations, for they are active and productive. There is always an abnormally high degree of activity in those elements that develop connective tissue. The only way in which fibroid tissue can develop is from growing cellular elements. Conditions of simple preponderance of fibroid tissue from the atrophy of other elements were not included under true fibrosis. Two forms of fibrosis were described, the hyperplastic and the inflammatory. The first is due to diminished nutritive supply, to parenchymatous atrophy, to nuclear proliferation and to connective-tissue hyperplasia. Inflammatory fibrosis is due to parenchymatous degeneration, to constitutional influences and to local attraction by the products of tissue-change—positive chemotaxis.

All agencies that diminish the vital forces by which the cell appropriates to itself its proper elements tend to the production of fibrosis. These agencies may be mechanical, chemical, or mental. Direct stimulation of fibrous growth, conditions including a limited degree of nutritive supply, conditions and elements that induce perverted nutrition, either degeneration or necrosis, including mechanical forces, perverted or defective nutritive supply, and toxic and trophic influences, may, any and all, cause fibrosis.

A diathesis may manifest itself by any bodily function displaying an activity out of proportion to the stimulant applied. In the fibroid diathesis, the growth of fibroid tissue is out of proportion to the degree of stimulation. Fibroid processes are not always injurious, as is seen in cases of cured tuberculosis. In seventy cases of cured tuberculosis under the observation of Dr. Loomis, fifty-four presented well-marked evidences of fibrosis. Diathesis often determines the nature or prominent action that follows a given irritant or stimulation, provided more than one is possible. It also modifies the ratio between the established process and its causes.

Dr. William Osler, of Baltimore, considered the fibroid process under the heads of degenerative, inflammatory and developmental. The degenerative were subdivided into the atrophic, the secondary degenerations, the toxic forms, as from lead, ergot, syphilis, the scleroses associated with similar changes in the smaller arteries and capillaries. Degenerative fibrosis is the most common. Inflammatory fibrosis was subdivided into secondary forms, in consequence of reactive inflammation following hemorrhage, tumors, foreign bodies, abscess and trauma, the scleroses that follow primary encephalitis or myelitis.

The following questions were suggested for consideration:

1. What is the relation of vascular change to the degenerative scleroses? How far histologically are they mesodermal or ectodermal, or are they mixed, containing both neurogliar and collagenous connective tissue?

2. In the lobar scleroses of children, what is the nature of the primary affection? Is it inflammatory, an encephalitis or meningo-encephalitis, or is the essential lesion in the vessels?

3. Can a purely ectodermal form be recognized in developmental fibrosis?

Dr. Charles L. Dana, of New York, then dwelt upon the chronic fibroid processes of the spinal cord, which he classed into primary degenerative, secondary degenerative, and reparative and inflammatory. The first includes locomotor ataxia, lateral sclerosis, combined scleroses, progressive muscular atrophy, and amyotrophic sclerosis. These scleroses are not inflammatory, but due to the primary destruction of cells and fibers. The causes of this degeneration were either toxic or disturbances of nutritive equilibrium by infections, vascular strain, or imperfect nutritive supply. They are not related to any special diathesis. The secondary fibroid processes have been shown to be probably neurogliar proliferations or gliosis, not a fibrosis. The inflammatory scleroses, including chronic myelitis, diffused myelitis, and transverse myelitis, are mixed processes, dependent upon a simple necrotic process, inflammatory processes, and secondary degenerations.

Dr. William T. Councilman, of Baltimore, discussed the fibroid process found in the liver, giving the results of investigations made in the Johns Hopkins Hospital. He dwelt upon the fact that the first element in the fibroid process was a necrosis. The fibrosis is not the result of stimulation. The tendency to growth is always present, and manifests itself as soon as the inhibition is removed.

AMERICAN SURGICAL ASSOCIATION.

Twelfth Annual Meeting, held at Washington, September 22, 23, 24, and 25, 1891.

FIRST DAY—SEPTEMBER 22D.

THE session was opened by DR. CLAUDIUS H. MASTIN, of Mobile, who delivered the President's Address. He expressed his appreciation of the importance of the trust that had been confided to him, and acknowledged the great honor of his position. He extended a cordial welcome to the members of the Association, together with their distinguished *confrères*. He traced the progress of the Association from its organization, eleven years previously, and paid an eloquent tribute to its founder, the late distinguished Samuel David Gross. The conception of the American Surgical Association was not in antagonism to the American Medical Association—quite the contrary. From the day on which the American Medical Association was organized Dr. Gross had been an active and influential member, once its President, often a contributor to its volume of *Transactions*. Governed by its code of ethics, he remained true and loyal to all its requirements, as evidenced by the fact that when on his deathbed he was asked by a friend what message he desired to send to the American Medical Association, he replied: "Give them my love." The last paper he wrote was being read in that Association during its session of 1884, on the same day that he died.

The first regular meeting of the American Surgical Association was held at Coney Island, and was attended by a small number of members. The second meeting was held at Philadelphia, with an attendance of twenty-five members. The third session was convened at Cincinnati, forty Fellows constituting its strength. The first volume of the *Transactions* was published subsequently to this meeting: Everything seemed to foreshadow a bright future, and nothing transpired to dim the occasion save the absolute refusal of its beloved founder and President to accept a reëlection to office.

That great man, the Nestor of modern American surgery, the founder and the cherished idol of the American Surgical Association, Samuel David Gross, standing without fear and without reproach, held that he had no preëmption right to office, and contended that he had occupied it long enough. He thought that his reelection would be at variance with the genius of our republican institutions and the habits of the American people. He believed that rotation in office should be the order of the day, not only among politicians but among scientists and professional men. He felt that his highest ambition, as respected this Association, had been accomplished. He appreciated clearly that the results of the work that he had begun were exceeding his most sanguine expectations, and were surely destined to pass into history. We knew that we were losing the guiding hand of a great pilot, and we were loath to permit him to leave the helm of office to serve in the ranks. In the language of a gifted Fellow of this Association, "Had the constitution conferred upon us the power, we would have put on him the royal purple, and hailing him chief among all, have bid him wear it for life." But he was inflexible, and that meeting was the last he ever attended. Those of us who were present on the closing day of that session can never forget the trembling words and tearful eyes when he said: "Now that I am about to retire from the discharge of these duties, I feel sure that the interests of the Association will be perfectly safe in your hands and in the hands of my distinguished successor. I have no greater ambition than to live in your affection and esteem, and to witness the ever-increasing prosperity of this Association. Its success is closely associated with the remainder of my life. I believe that we have an Association that is destined to become a power for good in the land, and when I am dead and gone you will not, I am sure, relax in your efforts to make it what its founder intended it should be—a great and lasting institution. God bless you, gentlemen, in all the relations of life! And may you ever be faithful to the interests of the profession, and the code of ethics in connection with which we have carried on our work."

Gentlemen, these were the farewell words of an old patriarch to his children, and they should sink deeply into your memories, for they were spoken by a truly great man, one of those who are "born beneath the aspect of a bright-eyed star, and whose triumphant adamant of soul is but the fixed persuasion of success."

In less than one short year from that day, he rounded up his great life and rested.

Subsequent successive and successful meetings were under the guiding hands of Moore, Briggs, Gunn, McGuire, Agnew, Cheever, and Yandell.

When this Association was first organized, anesthesia had but enlarged the domain of surgery. To-day antisepsis followed by asepsis has emboldened the surgeon to undertake and perform operations hitherto deemed impossible.

Whilst anesthesia had measurably lessened shock, antisepsis, with asepsis, has gone a step beyond, and done much toward the prevention of septic results, thus making the possibilities of surgery even greater.

In the last decade, the rapid and steady advances of the chirurgic art have far outstripped all other departments of the profession, and with the constant and seemingly never-ending improvements going on in all the branches—the discoveries in chemistry with the consequent additions to our materia medica; the revelations by the microscope, leading to a proper understanding of pathological lesions, and the clearing up of doubtful points in physiology, together with many new precisions in the study of all the branches of medicine—have enlarged the vista before us, so that no one can predict the limitations that may not be reached in the next ten years. It was but yesterday when the closed cavities of the body were held as sacred: the organs within the abdomen; the lungs and heart within the thorax; the brain and spinal cord cased by the skull and vertebral column, were each surrounded by a dead-line that none dared to cross. To-day they have each become the legitimate field into which the surgeon has carried his knife.

Dr. Mastin suggested that a business committee be appointed to prepare and arrange the scientific work of the meetings; such a committee, duly authorized, would relieve the president and secretary of much labor and responsibility, and the work that they would accomplish would better serve the interests of the Association than if left to the will and pleasure of the presiding officer.

He also suggested that the existing limit of fellowship be increased from one hundred to one hundred and fifty, at the same time urging that all due vigilance be exercised in the admission of new Fellows, so as to maintain the present high standard of the Association; age, scientific attainments, with surgical experience and general culture, should be the necessary prerequisites for admission.

Concluding, Dr. Mastin said that it is well known to the world at large, no less than to the profession of which he was an honored member, that Samuel David Gross stood first in the foremost rank in his chosen branch of the profession, and that the high position to which American surgery has attained all over the world is largely due to his example and his teachings. Since he has passed away and his life-work has gone into history, his real worth is fully appreciated, and therefore it is that his friends and admirers have been inspired to erect a monument to his memory—such a monument as will bear testimony to their gratitude and in the future be an incentive to those who are to come after us to do like noble deeds. To further this praiseworthy enterprise, Dr. Mastin suggested that a committee be appointed to confer with the friends and admirers of Dr. Gross, and with the medical profession of the whole country, to determine the best method to be adopted to secure the requisite amount for the erection of a monument either of marble or of bronze.

Dr. Gross was probably more widely known and appreciated than any American surgeon of recent years, and when it is remembered that thousands of his pupils are scattered throughout the whole of America—men who sat under his teaching and who still retain the warmest memories of him, it is not expecting too much to feel assured of their coöperation in raising speedily and without difficulty the requisite amount for the completion of such a monument.

This work should not be done by the Association exclusively, but by the profession of the entire country, because Dr. Gross belonged to no exclusive faction, but was a member of the profession at large. The American Surgical Association, however, should take the initiative in the movement, and there will not be the least doubt as to the successful issue of the undertaking.

If any man in the profession has merited such a tribute, surely Dr. Gross was most eminently entitled to it; for he was a man "animated by fervent attachment to the science and practice of his profession, and it was the duty of his life to augment and exemplify the resources of surgery; and by most assiduous and successful application of his time and his talents, his name has become known and honored, not only in his own country, but in every land."

Appreciated and honored as he has been in life, since he is dead such a monument to his memory should be built as will bear witness in after years to the estimate in which the profession of to-day holds its distinguished members.

If asked where such a statue should be erected, the answer would be, not at Easton, in the State of Pennsylvania, the place of his birth; neither at Cincinnati nor Louisville, where he laid the foundations of his future greatness, nor even in the city of Philadelphia, where that greatness culminated in all its grandeur; but in the city of Washington, the capital of the country which claims him as her own. His name and fame are a sacred heritage to the country at large and to the profession he loved so well, so that when the youth of the land make their pilgrimages hither they will behold the monument that their forefathers reared to commemorate the life and character of her greatest surgeon. It will teach them to emulate his example.

DR. D. HAYES AGNEW, of Philadelphia, read a paper on "The Present Status of Brain-surgery Based on the Practice of Philadelphia Surgeons." He confined himself to the work done by Philadelphia surgeons in trephining for epilepsy, traumatic and Jacksonian epilepsy, intra-cranial abscess, hemorrhage, hydrocephalus, cephalalgia, microcephalus, and neoplasms.

Traumatic epilepsy. Of this condition 57 cases were recorded. Of this number, 41 recovered from the operation; 4 died; and in 12 the result is not given. 32 experienced temporary relief, 9 obtained no benefit, 4 passed out of observation, 4 were operated on too recently to permit of the result being determined, and 4 are reported cured. In 1 of the cases reported cured the patient has been free from attacks for twenty-eight months; in 2, each for ten months; in the fourth a branch of the great occipital nerve was found imprisoned in the bone-cicatrix. While the results in these cases have not been satisfactory, it by no means follows that surgery holds out no hope against epilepsy. It is not saying too much to assume that surgery is responsible for the great majority of cases of traumatic epilepsy. This statement does not by any means criminate the surgeon of earlier days. Whenever the profession can accept the doctrine that all depressed fractures, however slight the depression and entirely irrespective of pressure-symptoms, are proper subjects for trephining, then will traumatic epilepsy largely disappear from the list of surgical diseases. In view of the greatly diminished risk of trephining, it is not improbable that the operation will be extended even to cases of simple fracture or fissure of the skull.

Jacksonian epilepsy. In each of 14 cases, the discharging center was removed; 9 recovered, and 4 died. Of those that recovered, 3 had less frequent and less violent attacks; 1 realized slight benefit; 1 disappeared shortly after operation; and in 2 no benefit was observed; 1 is reported as cured, and in that case the operation was done during the present year.

Abscess. Of 18 cases of abscess 6 had had fracture of the skull; 2 had syphilitic necrosis; in 1 a foreign body had entered the brain; in 9 the abscess was due to middle-ear disease; and in 2 there had been a severe blow, without fracture of the skull. All the patients died in less than fourteen days.

Five cases of trephining for *intra-cranial traumatic hemorrhage* are recorded. In each instance the symptoms necessitating operation developed within twelve hours after the reception of the injury. Four of the five cases recovered not only from the operation but with the restoration of the suspended functions.

Of trephining for *acute* and *chronic hydrocephalus*, five cases are reported; all the cases died, one living to the forty-fifth day. As hydrocephalus is usually due to tuberculous disease or to morbid growths, it is difficult to understand on what ground such operations are undertaken.

Cephalalgia. In five cases the focus of pain was referred to the neighborhood of a scar on the scalp. In four, complete relief was afforded.

Seven cases are reported in which trephining was performed for *microcephalus*. Of these four died and three recovered from the operation. One of the deaths, however, was due to scarlet fever occurring shortly after the operation. The result in the successful cases is reported as moderate improvement. From the results obtained from the education of idiots, it was thought wiser to relegate these unfortunates to special training-schools rather than to the trephine and rongeur. The debatable cases would be those accompanied with athetosis, in which condition some improvement might be obtained.

Brain-tumors. Only four operations for brain-tumors have been performed by Philadelphia surgeons. In one the growth was a fibroma weighing four ounces. The operation was performed by Dr. Keen, December 15, 1887, since which time the patient has had only six epileptic seizures. In the second case, also operated on by Dr. Keen, the tumor was in the occipital lobe and not removable. The patient died on the following day from shock and hemorrhage. In the third case no tumor was found. In the fourth a cyst occupying the cuneus was found and emptied; the patient died in thirty-six hours. At the autopsy a large sarcoma was found occupying the temporo-sphenoidal lobe.

The following deductions were made:

1. In view of the late after-effects, all fractures of the skull attended with depression, however slight and entirely irrespective of symptoms, should be subjected to the trephine. 2. Trephining for traumatic epilepsy at best promises only palliation. 3. Trephining for Jacksonian epilepsy is to be regarded as only affording temporary benefit. 4. In view of the fact that all such cases left alone almost invariably terminate fatally, trephining for abscess is entirely proper; the earlier such operation is done the better. 5. Trephining for intra-cranial traumatic hemorrhage is both an imperative and highly promising operation. 6. Medicinal measures having failed, trephining for cephalalgia should be undertaken, with every prospect of success. 7. Trephining for hydrocephalus is a useless operation. 8. Trephining for microcephalus, independent of athetosis, confers no credit upon surgery. 9. It is more than probable that as our observations multiply, the sphere of the trephine as a preliminary for the removal of brain-tumors will be lessened rather than amplified.

In the discussion, MR. JOHN CHIENE, of Edinburgh, did not take the same somber view in regard to traumatic epilepsy as did Dr. Agnew. He referred to three cases in which decided benefit had followed operation. He fully agreed with what had been said in regard to operation in depressed fracture, whether or not symptoms be present. The cleansing of the scalp is a difficult matter, but may be accomplished by shaving and soaking with a carbolic lotion for three days. For opening the skull, he advised the gouge and mallet as safer than the trephine. For enlarging the opening the gouge-forceps fulfil a useful purpose. For puncturing the dura and the brain he uses a Graefe knife. Hemorrhage from the bone may be checked by plugging with a match-stick; bleeding from the brain by hot water. Stress was laid upon the necessity of constant observation of brain cases. In a case of supposed injury to the head (but which later proved to be a case of apoplexy), in which the patient was in a dying condition, great improvement, eventuating in practical recovery, followed trephining.

DR. W. W. KEEN, of Philadelphia, held that every case of depressed fracture, even in young children, should be operated upon. A blow upon the head, not sufficient to cause fracture, may produce laceration of the dura or of the cortex. In regard to linear fracture, however, he was disposed not to accept the view that operation should be performed. In regard to tapping of the ventricles, he thought that further experience and an improved technique would lead to better results. In epilepsy, he suggested the use of the bromides after an operation had been performed. In many cases of brain-tumor, in which there is no hope of removing the growth, great comfort may be afforded the patient by removal of bone.

DR. CHARLES B. NANCREDE, of Ann Arbor, reported cases in which cures had followed operation for traumatic epilepsy. In one the cure was of ten years' duration. Often, cases that are reported as failures soon after the operation prove to be cures when followed for a longer time. The operation removes only one of the elements causative of epilepsy. In speaking of these operations, he stated that hemorrhage from the skull could be checked by forcing in the diploë. In regard to simple fissured fracture, he asked how the diagnosis could be made.

DR. ROSWELL PARK, of Buffalo, differed from Dr. Agnew as regards the results of operation for epilepsy. He had himself had cases in which decided benefit was afforded. In order to determine the effect, time must elapse so that the epileptic habit may disappear. The operation removes the anatomical cause, but ordinary therapeutic measures are needed to counteract the secondary conditions. Reference was also made to the relief afforded in brain-tumors, even when the removal of the growth was not contemplated. He reported two cases of craniotomy for microcephalus in which benefit had followed.

DR. H. C. WOOD, of Philadelphia, thought it well to wait before coming to any conclusions as to the results of treatment, either medicinal or surgical. He referred to one case in which, under medicinal treatment, the attacks remained absent for seven years and then returned. In these cases he advised that before the contemplated operation was performed, a mock operation should be done and the effect noted. He cited cases in which such measures had been followed by benefit.

DR. J. J. PUTNAM, of Boston, thought that a simple, smooth, depressed fracture would not be likely to cause any symptoms. The irritation from a sharp spicule of bone would probably cause irritation. Probably the most important element in the causation of trouble is the result of the original injury to the cortex. The interstitial changes in the cortex take the form of sclerosis, and it seems, *à priori*, doubtful that the removal of the bone would materially affect the condition. The operation may not prove indifferent, for the cicatrization of the incised wound may lead to harm.

MR. THOMAS BRYANT, of London, had been much struck by the emphasis with which Dr. Agnew had insisted upon the treatment to be followed in depressed

fractures. As a practical rule, he was disposed to agree with him, but there are certain exceptions. He did not think it wise to encourage the practitioner to trephine and elevate in every case of depressed fracture. He could recall many cases of depressed fracture, followed for years, in which no symptoms appeared. Depression of the lateral surfaces of the skull are not so apt to be followed by symptoms as depression of the vault of the skull. From these remarks, he said, it would naturally follow that he disagreed with the observation that in every case of fissure of the skull operation should be performed. He wished Dr. Agnew had gone more thoroughly into the reason for this statement. If there have been no brain symptoms, although the blow may have been sufficient to cause fracture, it would not be wise to insist that we should at once proceed to explore, to see if there is fracture. It is better to wait and watch for symptoms, being ready to operate as soon as there is a suggestion of something wrong. Although the risk of exploratory operation may be slight, yet it must be admitted that such operation is attended with some danger.

In conclusion, Dr. Agnew said that in traumatic epilepsy he did not condemn operation, but curative results should not be expected from it. Its result is only one of amelioration. He could not withdraw his statement made in the paper, for in many of the cases of traumatic epilepsy there had been no history of unconsciousness or other symptoms; there had been a blow on the head and many years later epilepsy appeared. It is impossible to determine the condition of the internal table of the skull by inspection of the external table. He had seen a simple crack in the skull with the internal plate forced some distance downward.

A paper on "Resection of the Wrist," by Dr. Rafael Lavista, of the City of Mexico, was presented and read by title.

Dr. Stephen Smith, of New York, presented the Report of the Committee on the Results that Should be Considered as Satisfactory, of Treatment of Fractures of the Shaft of the Femur, which is elsewhere published in the current number of The Medical News.

Second Day—September 23d.

Dr. A. G. Gerster, of New York, read a paper on "Aseptic and Antiseptic Details in Surgery," the full text of which is to appear in *The American Journal of the Medical Sciences*. He stated that personal cleanliness, and cleansing of the field of operation, are to be accomplished by mechanical measures rather than by disinfectants. The dirt and oily matter of the skin are removed by emollient potash-soap and a stiff brush. Then a germicidal lotion is applied. The hands of the surgeon may be sterilized by first trimming the nails short, then for one minute scrubbing the hands with soap, brush, and hot water. The nails are then cleaned, and the hands immersed in strong alcohol, and then washed in 1 : 1000 corrosive sublimate solution. Brushes require careful attention. They may be sterilized by boiling for five minutes in water containing one per cent. of washing soda. They should be kept in 1 : 1000 bichloride solution. Instruments are sterilized by boiling for five minutes in a soda solution, in a covered vessel. The addition of the soda prevents the formation of rust. Dressings are rendered absorbent and sterilized by steam. Strong antiseptic agents in dressings are objectionable from their action on the skin. Dressings may also be sterilized by boiling in soda-lye or potash-lye. The use of Florida sponges was recommended, for, owing to their cheapness, they can be used once and then thrown away. Boiling of sponges is to be condemned; sponges are best prepared by beating, followed by immersion in dilute hydrochloric acid. The acid is removed by washing. The sponges are then immersed in water for ten days, to permit the spores to germinate. Each sponge is then kneaded in hot water for one minute, with potash-soap or soft soap, and then, for twenty-four hours, placed in a five per cent. carbolic solution. As a substitute for the large flat sponges used in laparotomy, Dr. Gerster recommended the substitution of pads of absorbent gauze.

In operating, as few instruments, sponges, and assistants as possible should be employed. The dissection should be clean, the tissues cut rather than torn. Irrigation should not be employed except when special indications are present. Irrigation of the abdominal cavity was condemned. When the peritoneal cavity is contaminated by pus, simply wiping away the matter is sufficient.

In perfectly aseptic operations, no drainage is required. Iodoform gauze can often be substituted for tubes. Drainage by tubes is required when there is progressive suppuration.

In combating septic morbid processes, mechanical measures, such as incision, drainage and irrigation, are of more importance than chemical measures.

In the discussion that followed, Dr. J. Collins Warren, of Boston, described the details of operative surgery as practised in the Boston City Hospital, the Massachusetts General Hospital and the Children's Hospital, of Boston.

Dr. J. William White, of Philadelphia, expressed the view that the time had not yet arrived when the use of antiseptics could be dispensed with. He preferred an antiseptic dressing in all cases except when the wound is absolutely sterile and when no discharge is to be expected. While, in a general way, he agreed as to the value of mechanical measures in cleansing the skin, he saw no good reason for entirely throwing aside the use of the weaker chemical solutions. There are so many cases in which one cannot be sure that the wound is aseptic that antiseptic dressings become of importance. He had tried gauze as a substitute for sponges in abdominal work, but had found it objectionable from the fact that when the gauze remains long in contact with the intestines threads of gauze adhere to the intestine.

Dr. Joseph Ransohoff, of Cincinnati, stated that in some cases it was absolutely impossible to render a part aseptic. In cases in which it becomes clear that the wound is infected, he removes the dressings and soaks the part in hot water. He had discarded the use of sponges altogether. In the majority of cases he employs the aseptic dressing, but could see no harm in the use of antiseptic dressings. In private practice, dressings may well be sterilized by heating in the oven. He thought that tight closing of the wound should be practised oftener than it now is. Drainage is rarely used except in wounds already septic. He often uses

catgut for drainage. In the septic cases, he thought that probably the surgeon was often responsible for the infection of the wound. By clean incisions, cutting far away from the disease, and by not using the sharp spoon too freely, infection of the wound in suppurating cases can often be prevented.

DR. E. M. MOORE, of Rochester, inquired as to the objections to irrigation. In amputation, for instance, irrigation with 1 : 1000 bichloride solution affords a ready means of removing clots, leaving the wound dry. If irrigation does no harm, why not use it? Dr. Gerster had condemned it, but he had failed to give reasons for such condemnation. In certain cases of abdominal section, especially when there was oozing of blood, the irrigations of hot aseptic water were of great service.

DR. GERSTER, in concluding, said that he did not condemn antiseptic methods. He employed both aseptic and antiseptic methods. In its proper place, asepticism is infinitely superior to antisepticism; but the cases must be properly selected. Teachers must be careful not to go too far in advance of the rest of the profession. Those who have not learned the details should be warned to adhere to the older methods, gradually approaching the higher.

DR. J. WILLIAM WHITE, of Philadelphia, read a paper on "The Surgery of the Spine." He considered congenital deformities, tuberculosis of the spine, neoplasms and traumatisms. Under the first head, spina bifida was the only condition requiring consideration. In this, injection of an iodo-glycerin solution offers the greatest prospect of ultimate recovery, with the least immediate danger. In tuberculosis of the spine, the indications for interference are the evacuation of pus, removal of a sequestrum or of a focus of carious bone, and relief of pressure on the cord. Fourteen operations upon the bodies of the vertebræ are on record, with eight cures; five cases improved, and one death from causes distinct from the operation. There have been forty cases of operation on the spine for the relief of pressure. In twenty-two there was either improvement or cure. The effect of suspension in the treatment of Pott's paralysis has been so favorable that it should occupy a preëminent position.

Dr. White formulated the following conclusions in regard to the operative treatment of spinal tuberculosis, with symptoms of pressure on the cord:

1. In Pott's disease the paralysis is not, as a rule, due to transverse myelitis or hopeless degeneration, and usually not to the pressure of carious or displaced vertebræ, but in the majority of cases is the result of an external pachymeningitis that gives rise to the formation of an extra-dural connective-tissue tumor.

2. Speaking generally, a favorable prognosis is to be given, especially in children, in cases of Pott's paralysis in which the abscess (if any exists) can be evacuated; the treatment by extension and with plaster-jackets can be employed, and the patient placed under the most favorable hygienic conditions.

3. In cases in which other measures have failed, in which the disease is slowly but steadily progressive, with loss of motion and sensation below the level of the lesion, with incontinence of urine and feces, and the development of bedsores, and especially when acute symptoms threaten life, resection becomes entirely justifiable.

4. Operation having been decided upon, the prognosis will be favorable in direct proportion to the youth and strength of the patient, the non-involvement of vital parts, and the absence of generalized tuberculosis.

5. When the tuberculous process affects the arches and there is paraplegia, operation may be undertaken in the hope of not only freeing the cord, but at the same time removing the focus of disease. This double indication may also be fulfilled in cases in which, without bone-disease, there is posterior pachymeningitis or a tuberculoma occupying the spinal canal.

6. If the lesion of the bodies of the vertebræ is in the lumbar region, at a point where these bodies are accessible, it might in certain cases be possible to expose the cord from the back by removing the laminæ, with the object not only of relieving pressure but of reaching and taking away the diseased bone and tuberbulous granulation.

7. In tuberculosis of the body of a vertebra and compression of the cord by anterior pachymeningitis, only one indication can be fulfilled—to liberate the cord from pressure. In grave cases, operation should be undertaken only when acute compression, the appearance of respiratory complications, the rapid development of degenerative processes urgently indicate interference, or when the course of a chronic case is steadily progressive toward a fatal termination, although no advanced visceral tuberculous lesions are present.

In regard to neoplasms it was stated that every case of focal spinal lesion, thought to be dependent on a tumor and not distinctly malignant and generalized, should be regarded as amenable to operative interference, no matter how marked or how long-continued the symptoms of pressure may be. The indications and contra-indications for trephining in spinal fractures are based on the following points: 1. The nature of the vertebral lesion and the nature and extent of the medullary lesion. 2. The time that has elapsed since the traumatism. 3. The regional level of the medullary lesion.

The following conclusions were presented:

1. Some objections urged against operative interference in spinal traumatisms—*i. e.*, hemorrhage, frequency of absolute destruction of the cord, pressure from inaccessible fragments of bone, etc.—have been shown to be unsupported by clinical facts; others were largely due to a well-founded dread of (*a*) the shock in those cases operated on in pre-anesthetic times, and (*b*) consecutive inflammation, suppuration, and pyemia in pre-antiseptic periods.

2. Some results of recent operative interference in properly selected cases of fractures of the spine are encouraging, and should lead to the more frequent employment of resection of the posterior arches and laminæ: (*a*) in all cases in which depression of those portions either from fracture or dislocation is obvious; (*b*) in some cases in which, after fracture, rapidly progressive degenerative changes manifest themselves; (*c*) in all cases in which there is compression of the cauda equina from any cause, whether from anterior or posterior fracture, or from cicatricial tissue; (*d*) in the presence of characteristic symptoms of spinal hemorrhage, intra-medullary or extra-medullary.

3. Operation is contra-indicated by a history of such severe crushing force as would be likely to cause dis-

organization of the cord. The question that will remain in doubt previously to operation will usually be that of the extent of damage done to the cord and the possibility of its taking on a reparative action. As to this, the safest rule is that which has been formulated by Lauenstein, namely, that if, after the lapse of from six to ten weeks, there is incontinence of urine or incontinence of feces, and especially if extensive bedsores develop, but little is to be hoped for from the unaided efforts of Nature. If, however, these symptoms are absent, and if there be the least improvement, it will be proper for the surgeon still longer to delay operative interference.

In the discussion that followed, DR. H. H. MUDD, of St. Louis, dwelt upon the importance of remembering the likelihood of severe shock in these spinal operations. He reported three cases of bullet-wounds of the spinal column, one of which ended fatally.

DR. JOHN B. ROBERTS, of Philadelphia, insisted that injuries and diseases of the spine of a surgical kind should be treated as injuries of the cranial cavity are treated. Cases of Pott's disease with angular curvature have been referred to, but sufficient stress has not been laid upon the fact that many of these cases with motor paralyses improve under ordinary remedies, the inflammatory exudation being absorbed. In case of traumatism the spine should be explored as the brain is explored. In severe injuries, with fracture, spicules of bone are often driven down upon the cord.

DR. J. J. PUTNAM, of Boston, feared that the dangers of inflammation had not been sufficiently dwelt upon. After from one to four years some cases of spinal injury show some improvement. In such cases an operation may add to the improvement.

DR. JAMES MCCANN reported two cases of spinal injury in which operation had been performed. In one, death followed. In the other there was great improvement.

DR. N. SENN, of Chicago, presented the following conclusions upon "The Treatment of Tuberculosis of Bones and Joints by Parenchymatous and Intra-articular Injections."

1. Parenchymatous and intra-articular injections of safe anti-bacillary substances are indicated in all subcutaneous tuberculous lesions of bones and joints accessible to this mode of treatment.

2. Of all the substances so far employed in this method of treatment, iodoform has yielded the best results.

3. The curative effect of iodoform in the treatment of local tuberculosis is due to its anti-bacillary influence, and its stimulating action on the healthy tissue adjacent to the tuberculous focus.

4. A 10 per cent. emulsion in glycerin or pure olive oil is the best form in which to administer iodoform subcutaneously.

5. The ethereal solution should never be employed, as it is liable to cause iodoform intoxication, or necrosis of the tissues overlying the abscess.

6. Tuberculous abscesses and joints containing synovial fluid or tuberculous pus should always be thoroughly washed out with a 3, 4 or 5 per cent. solution of boric acid before the injection is made.

7. Injections should be made at intervals of one or two weeks, and their use persisted in until the indications point to the cessation of the tuberculous inflammation and the substitution for it of a satisfactory process of repair, or until the result of this treatment has shown its inefficacy and indications of the necessity of resorting to operative interference present themselves.

8. If the treatment promises to be successful, symptoms pointing to improvement manifest themselves not later than after the second or third injection.

9. In tuberculous empyema of joints, and in tuberculous abscess, gradual diminution of the contents of the joint-abscess at each successive tapping, with a lessening of the solids contained in the fluid, and increase in its viscidity, are the conditions that unerringly indicate that the injections are proving useful, and that in all probability a cure will result from their further use.

10. Moderate use of a limb is compatible with this method of treatment, provided the disease has not resulted in deformities that would be aggravated by further use of the limb. In such cases, correction of the deformity should be postponed until the primary joint-affection has been cured by the injections.

11. Parenchymatous and intra-articular medication, with anti-bacillary material, has yielded the best results in tuberculous spondylitis attended by abscess-formation and tuberculosis of the knee-joint and wrist-joint.

12. This mode of treatment may prove successful in primary osseous tuberculosis, followed by involvement of the joint, provided the osseous foci are small.

13. Extensive sequestra of articular ends, with secondary tuberculous synovitis, always necessitate resection, but preliminary treatment with iodoform injection into the affected joints, constitutes a valuable procedure preparatory to the operation, and adds to the certainty of a favorable result.

14. In open tuberculous affections of joints, incision, scraping, disinfection, iodoformization, iodoform-gauze tampon, suturing, and subsequent injection of iodoform emulsion are advised, and yield excellent results. They should be employed in all cases in which a more formidable operation can be avoided.

15. Balsam of Peru ranks next to iodoform in the treatment of tuberculous affections of bones and joints. If for any reason iodoform cannot be employed, or has failed in effecting the desired result, balsam of Peru should be given a fair trial, if operative treatment is not urgently indicated.

THIRD DAY—SEPTEMBER 24TH.

At the Executive Session the following officers were elected for the ensuing year:

President.—Dr. Phineas S. Conner, of Cincinnati.

Vice-Presidents.—Dr. L. McLane Tiffany, of Baltimore; Dr. Levi C. Lane, of San Francisco.

Secretary.—Dr. J. R. Weist, of Richmond, Ind.

Recorder.—Dr. J. Ewing Mears, of Philadelphia.

Treasurer.—Dr. John B. Roberts, of Philadelphia.

Member of Council.—Dr. Claudius H. Mastin, of Mobile.

The following resolution was adopted: *Resolved*, That the Association hereafter hold each triennial meeting at Washington, and that other annual meetings be held at such time and place as the Association may name.

It was decided to hold the next meeting in Boston, in June, 1892.

The following were elected to membership:

Dr. J. S. Wight, of Brooklyn; Dr. E. W. Walker, of Cincinnati; Dr. George R. Fowler, of Brooklyn.

The following honorary members were elected:

Mr. John Chiene, of Edinburgh; Mr. Reginald Harrison, of London; Mr. Thomas Bryant, of London; Mr. Arthur Edward Durham, of London.

DR. FREDERIC S. DENNIS, of New York, read a paper on "Recurrence of Cancer of the Breast." In all the cases considered a microscopical examination of the tumor had been made. Carcinoma is a disease of civilization. Seven thousand deaths occur annually in England from carcinoma, the breast being most commonly involved. In 75 per cent. of cases recurrence follows operation, including operations in which the axilla has not been opened. The primary neoplasm is local. Early and complete removal of the growth relieves the local disease, but does not overcome the predisposition or susceptibility or the capability of recurrence.

1. The recurrence of carcinoma of the breast is influenced by the interval of time between the appearance of the growth and the operation. The best results are obtained when the operation is performed early, particularly before involvement of adjacent glands has taken place.

2. Recurrence is influenced by the extent of secondary involvement, either by the blood-stream, by the lymphatics or by contiguity of structure.

3. Recurrence is influenced by the character of the operation. Complete removal of the breast is essential for permanent cure. Not only the breast, but the adjacent glands as well must be removed. In the seventy-one cases of Dr. Dennis there was but one death, and that was from hemorrhage in a case of hemophilia.

4. Recurrence is influenced by the histological character of the growth. The less typical the growth, the more unfavorable the prognosis. The more embryonic the structure, the greater the chance of recurrence.

5. Recurrence is influenced by the condition of the second breast. This is involved in 5 per cent. of cases. In these patients recurrence is likely.

6. Recurrence is influenced by the personal equation, including age, sex, marriage, fecundity, sterility, pregnancy, traumatism, heredity, menstruation, metastasis, mental condition, locality, etc.

In nearly all of the seventy-one cases reported, the axilla was opened, the entire breast was removed, together with all contiguous skin, the para-mammary and peri-mammary fatty areolar tissue, the pectoral glands, the pectoral fascia and the axillary glands and axillary fatty tissue. In some cases the supra-clavicular glands were removed, and in one case a number of the ribs were excised. The percentage of permanent cures reached 30 per cent.

Dr. Dennis held that with early and radical operation, recurrence of carcinoma of the breast should be comparatively rare.

MR. THOMAS BRYANT, of London, believed firmly in the local origin of carcinoma, although it must be admitted that there may be a predisposition to the development of the disease. Many cases do not come under observation until the disease is well advanced, because the patient imagines that a condition unassociated with pain cannot be carcinoma. When induration appears in a breast during the period of functional activity, there may be some hesitation in the diagnosis, but in some thirty cases of this kind in which immediate operation was performed, the disease was shown to have been malignant. In none has recurrence taken place. When the disease has advanced somewhat further, with dimpling and puckering of the skin and some immobility, a thorough operation may accomplish good results. In some cases there is no recurrence for from five to twenty years. In the more advanced cases the surgeon should limit his operations to those in which there is a reasonable prospect of removing all of the diseased structure. Mr. Bryant does not remove the axillary glands in every case. If the glands are enlarged or the disease extends toward the axilla he thoroughly removes the glands. If the disease is quite local and there is no evidence of axillary involvement, the axilla is not opened. In the atrophic form of carcinoma he though it better not to interfere, unless the tumor was a source of great inconvenience. In these cases operation is often followed by a more rapid form of growth. Again, in cases of carcinoma in which the lymphatics can be traced distinctly and the breast has a brawny feel—the lymphatic form of carcinoma—the surgeon does no good by interference.

SIR WILLIAM MACCORMAC, of London, thought that the axilla should always be opened in operations for carcinoma of the breast, for two reasons, viz.: (1) In 117 cases of carcinoma of the breast, examination showed that in all but 2 the axilla was involved; (2) In 90 per cent. of the recurrences the disease appears in the axilla.

DR. LEWIS S. PILCHER, of Brooklyn, thought that the term "recurrence" was not applicable to many of these cases, as the condition was simply one of continuance of the former growth. If a case goes for a year without the appearance of the disease, it may be considered that the disease has been removed; if it appears later, it can be regarded as recurrent, a renewed or a new attack of carcinoma. As in every case of carcinoma there is a predisposition to the disease, in addition to operative measures an agent should be sought to counteract this constitutional predisposition. Arsenic has, for many years, been used for this purpose. Dr. Wight, of Brooklyn, has suggested the use of carbonate of lime for the same purpose.

DR. L. MCLANE TIFFANY, of Baltimore, did not think that any limit could be set to the time at which recurrence might take place. He had seen the disease return eight years after operation. He firmly believes in the local origin of carcinoma. The time at which the disease is discovered by the patient bears no relation to the time of its commencement. Too much stress cannot be laid on the necessity for thorough operation. In only two cases, of eighty operations for cancer of the breast, had he found the axillary glands not enlarged. The pectoral fascia and at times portions of the muscle should be removed.

DR. KINGSTON, of Montreal, believed that carcinoma was essentially a local disease. Believing this, operation should be performed at as early a date as possible. The glands should be removed not only from the axilla, but if they are enlarged also from its neighborhood. If there should be recurrence the operation should be repeated as often as circumstances seem to warrant.

DR. JOSEPH RANSOHOFF, of Cincinnati, reported thirty

cases of removal of the breast for carcinoma, without a death. He thought that the danger of the operation was not materially increased by opening the axilla.

Dr. C. B. Nancrede, of Ann Arbor, said, with reference to the three-year limit, that this had been proved to exclude ninety-eight per cent. of the recurrences. It is impossible to tell whether or not the axillary glands are involved without opening the axilla. Unless this is done the majority of cases will be left unbenefited. He advised that the axilla be opened first, and if the glands could not be removed, to close the wound and not remove the breast.

Dr. J. R. Weist, of Richmond, Ind., had operated fifty-five times for carcinoma of the breast, and makes it a rule to open the axilla in every case.

Dr. George W. Gay, of Boston, would not admit the local origin of carcinoma. When it can be shown that a carcinoma, once removed, will not return, just as a fatty tumor when removed does not return, then the local origin of carcinoma can be accepted.

Dr. Edward M. Moore, of Rochester, always operates in as thorough a manner as possible. He always opens the axilla, and does not think that he thereby adds to the risks of the operation. He did not agree with Mr. Bryant in regard to the atrophic cases in old individuals. In these he recommended operation, considering recurrence very improbable. He reported one case, now seventy-nine years of age, living seventeen years after the operation.

Dr. C. B. Porter, of Boston, reported "A Case of Diffuse Fibroma with a Tendency to Intra-canalicular Growth of Both Breasts," in which for three years the breasts had undergone gradual enlargement, the increase in the last three months, however, being rapid. The greatest circumference of the right breast was 38 inches; the length from the chest-wall to the nipple, 17 inches; the circumference of the base, 23 inches. The greatest circumference of the left breast was 28 inches; the length from the chest-wall to the nipple, 14 inches; the circumference at the base, 23 inches. Throughout both breasts were felt hard, movable masses of irregular outline, varying in size from an orange to a closed fist. The left breast was first removed. It was transfixed at the base with two skewers and constricted below this by means of a tightly-drawn rubber tourniquet. But little blood was lost. Three weeks later, the right breast was removed. Twenty days after the second operation the patient was permitted to leave the hospital. A week later she developed erysipelas. This had improved in four days, when she suddenly aborted a four-months' fetus.

The weight of the right breast after removal was 43 pounds and that of the left 17 pounds.

Dr. J. M. Barton, of Philadelphia, reported a similar case, in which only one breast was removed.

(To be continued.)

AMERICAN GYNECOLOGICAL SOCIETY.

Sixteenth Annual Meeting, held at Washington, September 22, 23, and 24, 1891.

First Day—September 22d.

Dr. Joseph Taber Johnson, of Washington, delivered an Address of Welcome.

The first paper was presented by Dr. John C. Reeve, of Dayton, Ohio, on "The Advantages of Mixed Narcosis in Gynecological Surgery." There are special features of many operations of gynecology, abdominal and plastic, that require the most profound and uninterrupted anesthesia for their successful performance. This condition is assured by the hypodermatic injection of morphine and atropine before the inhalation. For more than twenty years Dr. Reeve has resorted to this procedure in every operation of notable duration or severity.

The advantages of the method consist in the facility of production of anesthesia; steadiness of its maintenance; profoundness; and diminution of struggling in the early stages, and of vomiting afterward.

The great point in artificial anesthesia is danger. The speaker adduced the points in support of the superior safety of the mixed method: 1. The emotional state is nearly abolished by the narcotics. 2. A much smaller quantity of the anesthetic is required. 3. A shortened and diminished struggling stage. 4. The stimulating influence of atropine upon cardiac action and respiration. 5. The effect of morphine in lessening reflex inhibition. 6. Experiments upon animals.

Finally, the question of the combination of the narcotics with ether was considered, since almost all experience had been with chloroform as the anesthetic. The speaker had exclusively used the A. C. E. mixture, which is one-half ether. His experience with the method had been unbroken by accident or by threatening of danger. He had used it in one patient that under a previous administration had the narrowest escape he ever saw under anesthetics, and there were no disturbing symptoms.

In none of the few cases in which death had occurred was this sudden and typical of death under anesthetics. In every instance the fatal termination took place some hours after the administration.

Dr. Warren Sawyer, of Chicago, stated that he had found mixed narcosis valuable in preparing patients for the application of the forceps, or other minor obstetrical procedure.

Dr. J. M. Baldy, of Philadelphia, stated that he had employed mixed narcosis, with ether as the anesthetic, but when he could have full personal control of the preparation of the patient for operation he had not found any essential difference between simple and mixed narcosis. He believed that most of the struggling of the patient during the anesthesia was due to gastro-intestinal irritation, and when he had cleared out the gastro-intestinal tract prior to the operation, the patient had remained just as passive as in the cases in which he had used mixed narcosis. He had seldom seen vomiting after ether-narcosis.

Dr. William T. Howard, of Baltimore, was strongly in favor of ether as an anesthetic because it took a much smaller amount to anesthetize a patient and the struggling was less. He believed that, although ether caused less nausea than chloroform, neither secured immunity from vomiting, and he was glad to hear of the good results of mixed narcosis.

Dr. John Byrne, of Brooklyn, had used mixed narcosis for many years, with ether as the anesthetic, and believed that all the good effects claimed by Dr. Reeve could be obtained as well when ether was used as the anesthetic, instead of the A. C. E. mixture.

DR. HENRY C. COE, of New York, read a paper entitled "Accidental Hemorrhage occurring During the First Stage of Labor, at Term." He considered only the hemorrhage occurring during labor. This is not only the more infrequent but the more fatal form, and is rarely of traumatic origin.

The etiology of these cases is obscure: traumatism is the most frequent factor before labor; the predisposing causes are a hemorrhagic diathesis, general febrile affections, renal troubles, death of the fetus, hydramnios, and diseases of the placenta. Irregular uterine contractions have been noticed in 20 per cent. of cases. In a certain number of cases the cause was undoubtedly abnormal shortness or twisting of the cord. In non-traumatic cases the accident cannot be ascribed to a single etiological factor; there is usually a combination of several. It is impossible in a given case to predict what combination may lead to hemorrhage.

There are two sets of symptoms—initial and final. Most writers affirm that the latter are alone reliable and are recognized too late for successful interference. Dr. Coe believes that it is possible to diagnosticate accidental hemorrhage at its inception by careful attention to the initial phenomena, especially irregularity and feebleness of the labor-pains. Sometimes the pains are strong and then die away; in many cases they are feeble from the outset. The patient complains of continuous pain in the lower part of the abdomen, which gradually grows worse and assumes a rending character. External palpation may at first reveal nothing abnormal; auscultation of the fetal heart shows it to be feeble and irregular. The patient may be restless and irritable, but able to sit up and walk about; her pulse is not affected, so that the ordinary observer may mistake the case for one of simple uterine inertia. External bleeding has been absent in three-fourths of the cases reported. Its occurrence should be regarded as a confirmation of a diagnosis already made. The patient's pulse and general appearance now indicate internal hemorrhage; the labor is entirely arrested; she grows weaker, collapses, and may die; or, after rupture of the membranes, strong pains may come on and the woman may be delivered, only to succumb to post-partum hemorrhage, if not to shock. In not a few instances death seems to be due to over-distention of the uterus rather than to actual loss of blood.

The condition might be mistaken for a severe attack of colic, but hardly if the condition of the uterus was carefully observed. It is distinguished from rupture of the uterus by the fact that rupture occurs during the progress of active pains, usually before the rupture of the membranes, and is followed by a diminution rather than an increase in the size of the uterus, by recession of the presenting part, and by the sudden onset of the symptoms of internal hemorrhage. In case of uterine atony dependent upon hydramnios, a quantity of liquor amnii escapes when the presenting part is returned.

The prognosis is dubious; it varies according to the time at which the accident is recognized, the degree of shock, and the character of the labor-pains. The child is likely to be lost. If the pains are fairly strong, the uterus not over-distended, the cervix dilatable and the head engaged, the patient ought to be saved. If she is in collapse, the uterus distended and absolutely inactive, and the cervix is rigid, so that time is lost in dilating it, the outlook is bad. When delivery is effected there is great danger of post-partum hemorrhage, which may destroy the patient, already exhausted.

There is a want of unanimity with regard to the management of these cases. Some advise an immediate delivery; others, delay. Dr. Coe disapproved of the practice of rupturing the membranes and administering ergot when there was no prospect of immediate delivery. It might cause the uterus to contract, but it did not overcome the obstacle to delivery, and might be a cause of a continuation of the hemorrhage. Dr. Coe's plan of treatment was as follows: As soon as the accident was recognized, the patient is vigorously stimulated by mouth, rectum, and hypodermatically, and assistance sent for. Under complete ether-anesthesia the os should be carefully dilated manually, Barnes's bags only being employed when the os is rigid and the patient's condition such that a certain amount of delay could be safely permitted; the membranes should be preserved intact; then version should be performed, with unusual care to avoid rough manipulation. At this stage ergot should be freely administered hypodermatically. There should be a short delay before extraction in order to give the uterus time to recover its tone.

If the head is arrested by the poorly-dilated os, it should be perforated instead of wasting time in trying to drag it out. The most important step is the prevention of post-partum hemorrhage. Instead of losing time by employing the ordinary agents, ice, hot water, astringents, electricity, etc., the hand should be introduced into the uterus, the placenta and clots removed, and the cavity at once tamponned with iodoform gauze. This will promptly arrest the hemorrhage, even if the uterus does not contract.

DR. EDWARD W. JENKS, of Detroit, presented a paper entitled, "The Therapeutic Aspect of Some Ovarian Disorders." He stated that, notwithstanding the brilliant achievements of abdominal surgery within the past few years and the large percentage of recoveries after successful operations on the ovaries and Fallopian tubes, there remains a dark spot on the face of perfection. Unfortunately, to operate and to cure have not ever been synonymous terms. There are, undoubtedly, many fatal cases of laparotomy of which, not being published, the medical world has no knowledge. There are also many instances of recovery from operations in which the patient is not benefited in the least.

Dr. Jenks entered a strong protest against the wholesale removal of ovaries by everyone considering himself capable of wielding a knife or tying a ligature. Operation for the relief of pain and for mental disorders, in anemic, neurasthenic and hysterical women frequently fails to accomplish the object sought for.

Upon the statements of many laparotomists it can be safely said that ovaries and tubes have been removed for pain or other symptoms when neither macroscopic nor microscopic examination indicated any diseased condition, and the patient was restored to health in consequence.

A simple catarrh of any mucous tract in the body, if neglected, often advances to the purulent stage, and Dr. Jenks had no doubt that in not a few cases operated upon in which pus was found in the tubes, the fluid was simply a slightly muco-purulent secretion, the result of

an undiscovered or neglected catarrhal salpingitis, which, in its earlier stages, would have been amenable to treatment by ordinary therapeutic measures. The fearful frequency of gonorrheal salpingitis has caused many to overlook the fact that there is any other variety.

While Dr. Jenks fully appreciated the feats of abdominal surgery, he believed it finer science to restore an organ to moderate usefulness and comfort than to remove the offender; but if treatment by ordinary therapeutic means could not bring about the necessary repair, then he would remove the organ without delay. He believed that some of these cases had a malarial origin, and he had accordingly treated some of them with success.

Contrasting the rich and the poor, there is in these cases an exception as regards women of the poorest class. They cannot afford a long period of semi-invalidism. They do not complain of sterility, as they generally have more children than they can take care of. The quickest possible amelioration of their troubles is the thing desired; therefore an operation should be performed at once after it has been decided that the tubes and ovaries are hopelessly diseased. On the other hand, in the case of the rich, who can afford to wait, time and judicious treatment will often bring about the desired result. The uterine sedatives, such as viburnum, piscidia, apiol, some of the coal-tar preparations, bromides, etc., are serviceable in quite a variety of conditions. Electricity is valuable as a general nerve-tonic for the relief of pain, and the dissolution of pelvic exudates and adhesions. Local treatment consists in painting the entire vaginal vault with a saturated solution of tincture of iodine, and keeping up continuous pressure by means of wool tampons.

Dr. J. M. Baldy, of Philadelphia, presented a paper entitled, "Insanity Following Gynecological Operations." A careful inquiry from the heads of eight hospitals for the insane throughout the country, as to whether any female patients were admitted during the past five years on whom laparotomy was performed and insanity followed, resulted in the following: Of a total of 15 cases, there was in 11 preëxisting insanity, and the operation was undertaken in the main for the cure of the mental condition. In four cases insanity followed the performance of laparotomy.

Mental disturbances follow gynecological operations more frequently than is supposed. When there is an inherited tendency to mental disease, laparotomy should only be undertaken with an understanding of the possible outcome.

Dr. Jos. E. Janvrin, of New York, read a paper entitled, "A Clinical Study of Primary Carcinomatous and Sarcomatous Neoplasms Between the Folds of the Broad Ligaments, with a Report of Cases." He stated that malignant neoplasms other than those of the ovaries sometimes do occur *primarily* between the folds of the broad ligaments, and related the history of three cases, one of sarcoma of the Fallopian tube, the second of primary carcinoma of the parovarium, and the third of cystic angio-sarcoma of the left broad ligament, with a lipoma of the right, and with dilated tubes.

The history of all three of the cases pointed plainly to the primary development of malignant growths, two sarcomatous, and one carcinomatous, within the folds of the broad ligament.

Than the second, Dr. Janvrin knows of no other recorded case of an adenoid hypertrophy in the parovarium undergoing degeneration and transformation into carcinoma; he also believes that there is no other recorded case of a primary carcinomatous development within the folds of the broad ligament, excluding those that develop in the ovary proper.

Dr. William H. Parish, of Philadelphia, read a paper entitled "The Present and Improving Status of Cæsarean Surgery," by Dr. Robert P. Harris, of Philadelphia.

Dr. Harris regards the new Cæsarean operation, *per se*, in the hands of a skilful operator and with the woman in good condition, as one of a moderate degree of risk. His personal experience covers 13 cases, with only two deaths.

The greatest obstacle to the success of Cæsarean surgery, more especially in the United States, is that cases are not brought to the obstetric surgeon until the risk of using the knife has been greatly increased by the effects of labor and attempts at delivery. Of the eighteen true Porro cases in the United States, the fetuses were already dead in eight before the knife was resorted to. The records of the most successful work in Europe show how intimate has been the connection between the living fetus and the subsequently-saved mother. The saving of the woman must thus begin with the management under the obstetrician first consulted. If he should happen to know the requirements for Cæsarean success, the case will probably be so managed as to attain it; otherwise the result may be decidedly adverse before he is fully aware of the necessities of the case.

Dr. H. Marion Sims, of New York, reported a "Unique Case of Multiple Neuro-lipomata Following Laparotomy," in which he excised the hymen for vaginismus, with a disappearance of the nervous symptoms. Eight months later, in the seventh month of pregnancy, the woman was seized with violent convulsions. The patient complained of violent pain in the left ovarian region. Examination revealed an enlarged cystic ovary jammed tightly between the uterus and the abdominal wall. Pressure caused excruciating pain.

The patient was made tolerably comfortable by inhalations of amyl nitrite up to the time of labor, when it was thought that she would be free from her hystero-epileptic attacks, by the removal of the pressure of the gravid uterus upon the ovary. Shortly after delivery, which was uneventful, the attacks came on with renewed violence, the other ovary also now showing signs of cystic degeneration. Her condition had become so distressing that laparotomy was performed. The convulsions entirely disappeared, and the woman made a good recovery.

Six months later the woman was again seized with intense circumscribed abdominal pain; the lightest touch caused the most acute pain. After considerable difficulty, a little tumor that felt like a large duck-shot was removed from the abdominal wall. On the following day, other growths in the abdominal wall were removed. Microscopical examination showed them to "consist of hardened fat and connective tissue, with a tiny nerve-filament running through the whole, and seemingly tightly in the grasp of the tumor itself."

Despite repeated removal the growths recurred, resisting all therapeutic measures. At the end of the second

year the growths showed evidence of disappearing, and in the thirtieth month from the first appearance of the growths, the last was removed, not to return. The woman has now enjoyed good health for three years, warranting the hope of permanent cure.

(To be continued.)

AMERICAN DERMATOLOGICAL ASSOCIATION.

Fifteenth Annual Meeting, held at Washington, September 22, 23, 24, and 25, 1891.

FIRST DAY—SEPTEMBER 22D.

THE meeting was called to order by DR. F. B. GREENOUGH, of Boston, who delivered the President's Address.

The first paper read was by DR. H. G. KLOTZ, of New York, entitled "Dermatitis Hemostatica."

DR. L. A. DUHRING, of Philadelphia, followed with a paper, "Report of a Case of Universal Erythema Multiforme," accompanied by a colored portrait of the case and specimens of large plates of exfoliated epidermis shed during the course of the disease.

DR. SHEPHERD, of Montreal, asked if any drug had been administered for the rheumatism that was a marked feature in the case, to which Dr. Duhring replied, "No. The treatment had been entirely negative."

DR. FOX, of New York, had seen a case somewhat resembling that of Dr. Duhring, in which there was a question as to whether or not the eruption had been caused by some drug that had been taken for a coexisting gonorrhea. He thought that it was a purely accidental occurrence, as exfoliation of the skin is often seen after other diseases, such as psoriasis.

DR. SHEPHERD, of Montreal, reported a case of "Sarcoma of the Arm Involving the Skin," for which amputation was performed. The patient was a healthy man, aged thirty-five years; no history of syphilis. A small nodule appeared two years previously over the ulna; this was at first movable; soon other nodules appeared, became attached to the skin, and finally ulcerated, the ulcers afterward fusing together, forming one huge, irregular ulcer, with sharply cut, indurated edges and sloughing base, having very much the appearance of a syphilitic ulceration. In a short time the chains of nodules, large and small, were seen extending along the inner side of the biceps muscle from the bend of the elbow to the axilla; they evidently followed the course of the lymphatic trunks. Some of these nodules were excised and pronounced by the pathologist of the hospital to be spindle-celled sarcoma. The growth apparently originated in the cutis, and the structures earliest involved were the lymphatics. The pain, which was most severe, occurred chiefly at night, and antisyphilitic remedies were for a time employed, but with no permanent benefit. Owing to the increasing ulceration, which rendered the arm useless, and the intense pain, the arm was amputated at the shoulder-joint. The axilla was found full of infiltrated glands that closely embraced the bloodvessels. The man remained well for a year, when there was great pain again and recurrence of the growth in the stump. This growth was excised, without much relief from the pain, however, so that later Dr. Shepherd resected the cords of the brachial plexus above the clavicle, with the result that since that time (three months) the pain has been completely relieved. The most interesting point in the case is the early, rapid, and extensive involvement of the lymphatics—an unusual course in sarcoma. Melanotic sarcoma not infrequently involves the lymph glands early, but not other varieties of sarcoma.

This was followed by a paper by DR. S. SHERWELL, of Brooklyn, upon "Multiple Sarcomata: History of a Case Showing Modification and Amelioration of Symptoms with Large Doses of Arsenic."

Dr. Sherwell removed in all from this patient thirty growths, some of which were quite large, one three and three-quarter inches in diameter. Dr. Wheeler about a year later, in a series of operations, removed the immense number of one hundred and seventy, large and small. In the interval between leaving Dr. Sherwell's care and coming under that of Dr. Wheeler, the patient had interrupted or almost suspended treatment with large doses of arsenic, which had caused the complete or almost complete disappearance of all growths. They recurred so rapidly that Dr. Wheeler adopted the same internal treatment that Dr. Sherwell had instituted, with the most decided and gratifying results, namely, the same rapid disappearance of the growths. The case, however, neglected treatment and died in a few months.

In the discussion, DR. ZEISLER, of Chicago, mentioned brilliant results in a case of lupous sarcoma from the administration of arsenic. In a case of pigmentary sarcoma he had given the drug without effect.

DR. J. C. WHITE, of Boston, had seen good effects from the use of the drug in one case of sarcoma.

DR. ROBINSON, of New York, had not had much success with arsenic. He believed that many cases of so-called multiple sarcomata were in reality microbic in origin and not true tumors.

The next paper read was by DR. R. B. MORISON, of Baltimore, on "The Hypodermatic Use of Hydrargyrum Formamidatum in Syphilis," which will appear in a later number of THE MEDICAL NEWS.

In the discussion, DR. CORLETT, of Cleveland, said that he had found hypodermatic injections of mercury of great use in some cases, such as those cases in which the stomach was rebellious.

DR. KLOTZ, of New York, had employed hypodermatic injections in syphilis. While they are doubtless of value, in most cases older methods of treatment are quite as good.

DR. GREENOUGH, of Boston, said that while greatly interested in the subject of hypodermatic medication in syphilis, he had found it impossible to get his patients to submit to it. He thought that it was useful only in exceptional cases in which other plans could not be used. Its ultimate result was no better than that of other plans.

DR. JOSEPH GRINDON, of St. Louis, Mo., read a paper entitled "A Case of Lichen Scrofulosorum." In this case the lesions were collected in groups and segments of rings extending over both scapular regions; they were miliary in size, firm, and in many instances pierced by hairs. Scattered among them were acne lesions. The picture, taken as a whole, was an almost exact counterpart of that of a small miliary papular syphilide.

The case was reported: 1st. On account of the rarity of the disease, not over a half-dozen cases having been

reported in the United States and Canada to date; 2d. The age and sex (female, twenty-two years) being unusual; 3d. Because of the further surprising fact that the family history and hygienic surroundings of the patient were of the best.

(To be continued.)

ASSOCIATION OF AMERICAN PHYSICIANS.

Sixth Annual Meeting, held at Washington, September 22, 23, 24, and 25, 1891.

FIRST DAY—SEPTEMBER 22D.

THE PRESIDENT, DR. WILLIAM PEPPER, opened the meeting with an address in which he spoke feelingly of the members who had been removed by death since the last meeting. Dr. Fordyce Barker and Dr. Joseph Leidy, both of whom are honorary members, were especially eulogized. In a few well-chosen remarks a cordial welcome was extended to the members of the Association and invited guests.

By a unanimous vote, DR. WILLIAM P. NORTHRUP, of New York; DR. ANDREW H. SMITH, of New York; DR. AMOS L. MASON, of Boston; and DR. A. MCPHEDRAN, of Toronto, Canada, were elected members of the Association.

The discussion on "The Treatment of Visceral Tuberculosis by Koch's Method" was opened by DR. F. P. KINNICUTT, of New York City.

From December 10, 1890, to June 1, 1891, Dr. Kinnicutt had inoculated 40 cases with tuberculin. The cases were classified as follows: Pulmonary tuberculosis, 13; laryngeal tuberculosis, 7; lupus, 6; tuberculosis of joints, 5; tuberculous adenitis, 4; tuberculous affections of bones, 2; tuberculosis of the prostate, 2; tuberculous epididymitis, 1; rodent ulcer, 1; for diagnosis only, 8. Only the pulmonary and laryngeal cases were dwelt upon.

Dr. Kinnicutt urged the necessity of using fresh solutions of tuberculin. One milligram was the maximum beginning dose; in some cases only one-half this amount was administered, the dose being gradually increased as tolerance was established.

He divided the pulmonary cases into (*a*) notable improvement in the local and general conditions; (*b*) no improvement, or result variable; and (*c*) distinct deterioration. The following are the conclusions reached:

The occasional harmful action of the remedy is recognized. It possesses marked affinity for tuberculous tissues. It does not confer immunity when injected into healthy bodies, but in some cases it seems to predispose to contagion or to light up a latent trouble. He does not consider the constitutional symptoms necessary to the beneficial action of tuberculin, but believes that the remedy is a very complex body, and that the efficient therapeutic principle is separate and distinct from that causing the constitutional manifestations, which he maintains are harmful rather than otherwise.

The use of tuberculin in pulmonary tuberculosis is useful only in the earliest stages of the disease. The establishment of tolerance differs widely in different cases. In incipient cases the remedy is apparently capable of exciting pneumonic processes; and in localized tuberculous pleurisy, a general pleurisy may follow its use.

Hemoptysis during the administration of the remedy is rare. Dr. Kinnicutt concludes that the remedy is useful in certain varieties of cases.

DR. HAROLD C. ERNST, of Boston, continuing upon the same subject, gave the result of his experience. He did not think the best results from tuberculin have been yet attained, but that the future may demonstrate some modification of the present remedy, or that something to which this may lead will yield valuable assistance in the treatment of tuberculosis. Of twelve cases of marked pulmonary tuberculosis, five were reported as relieved. He could not report any as cured. There were no deaths.

Of twenty-two surgical cases, two were much relieved; twelve were not relieved; and two died. The remainder, including such cases as lupus, and joint and glandular affections, were relieved. Here, again, no cases were cured. In a general way, the number of bacilli in the sputum bears some relation to the condition of the patient. He has observed marked and rapid improvement in some cases of tuberculosis, especially the external forms.

Dr. Ernst concludes that tuberculin does not possess any diagnostic value, so as to be of any service for clinical use. At times, temporary benefit results. He has had no experience with ill-effects after its use. The results obtained would not induce him to make further use of it in the treatment of tuberculosis.

DR. WILLIAM OSLER, of Baltimore, reported the result of the use of the remedy at the Johns Hopkins Hospital. Twenty-two cases of pulmonary tuberculosis and three cases of pleurisy were inoculated. None were cured; five were decidedly benefited in their general condition, gaining in weight from nine to fourteen pounds. The bacilli did not disappear from the sputum, but the cough decreased. Nine cases seemed worse for the treatment; in four the condition remained unchanged, and in four slight improvement resulted. No deaths occurred in patients under treatment. The three cases of pleurisy improved in general condition and in weight.

DR. J. P. C. GRIFFITH, of Philadelphia, who had charge of the ward for tuberculosis at the Hospital of the University of Pennsylvania, reported the results of the use of tuberculin in nineteen cases that he had carefully studied. In only one case did decided improvement follow; in this, the general condition became much better, but the consolidation at the apex gradually extended. A number of others improved in general health, but not more, perhaps, than could be accounted for by the favorable conditions incident to a well-regulated hygienic regime. In many cases the sputum and number of bacilli diminished. Albuminuria frequently followed the injections, and at times blood-corpuscles appeared in the urine. It was not possible to decide that the remedy caused the improvement in any case. One case was apparently made worse.

DR. J. W. ROOSEVELT, of New York City, followed with a paper entitled "Experimental Studies on the Causes of the Localization of Pulmonary Phthisis and Certain Other Infectious Diseases of the Lungs." Tuberculosis of the lungs usually begins in the upper lobes. The speaker objected to the generally accepted explanation of infection by inspiration of bacilli with the

dust of the atmosphere. In many experiments that he has made, he has been unable to force dust beyond the larger bronchial tubes in the lungs. He disagrees with those who believe the upper lobes of the lungs expand less than other portions. The bacilli seem first to lodge at the ultimate bronchioles. Dr. Roosevelt thinks that the bacilli gain entrance into the blood through the blood-channels and lymph-channels, by absorption through the mucous membranes of the nose, pharynx, and stomach, and, reaching the blood-stream, are arrested at the pulmonary capillaries. He also thinks that his experiments have demonstrated that foreign bodies in the blood-stream adhere to the upper wall of the vessels, hence the final lodgment in the upper lobes.

In the discussion, Dr. Welch disagreed with the view last mentioned, and called attention to the fact that embolic processes do not by preferment select the upper lobes. Miliary tuberculosis is less marked at the apices than at other portions, and hemorrhagic infarcts are rare at the apices. He queries whether the bacilli may not go to all parts of the lung, but find conditions at the apex of the lung more favorable for growth.

Dr. Ord, of London, also expressed his belief in the selective influence as the cause of the location of the initial lesion. Microscopical examination of apices of lungs in animals shows a less perfect structure than in the other portions, and he thinks that as a result there may here be a lowered resistance.

Dr. Jacobi, of New York, stated that he does not believe that a healthy lung is subject to tuberculosis, and that he considers tuberculosis by embolism rare. He believes infection generally occurs through a diseased mucous membrane, in the course of conditions like catarrh.

Dr. Vaughan, of Ann Arbor, called attention to the fact that the embolic cases of tuberculosis rarely affected the apices, and that therefore the theory advanced by Dr. Roosevelt could not stand.

W. T. Gairdner, M.D., LL.D., Professor of Medicine in the University of Glasgow, made some highly interesting extemporaneous remarks on "An Experience in Sanitary Administration in Connection with Cholera in Glasgow in 1866." In 1865 culminated a most severe epidemic of typhus fever, numbering its victims by thousands. The sanitary conditions of the city were exceedingly bad. An epidemic of cholera was anticipated, and the Privy Council communicated with Dr. Gairdner in reference to measures to combat the epidemic should it appear. Five small hospitals were built, and handed over to the parochial boards to take charge of all diseases except cholera, Dr. Gairdner and eighty assistants to assume entire charge of all cases of cholera, should they appear. Other measures were set on foot to inspire the people with confidence and teach them prophylaxis.

In September, 1866, the first case of cholera was reported; by December the epidemic had disappeared.

The highly satisfactory result of the organization described, led Dr. Gairdner to consider a plan for permanent operation, and to be followed in similar epidemics.

Second Day—September 23d.

The discussion on the "Remote Results of the Removal of the Ovaries and Tubes" was opened by Dr. William T. Lusk, of New York, Referee, who made a strong appeal for greater conservatism in pelvic surgery. During the preceding five years he has removed the ovaries and tubes in sixty-five cases for degenerative changes or myomatous growths.

Dr. Lusk objects to the removal of healthy ovaries and tubes for the various reflex disturbances and nervous symptoms commonly supposed to depend upon these organs. He considers normal ovariotomy little short of malpractice. He believes, however, that Tait's operation has a useful field. Recovery may be expected in hydrosalpinx, and should the diagnosis be uncertain, he does not hesitate to use the exploring needle. In cases of pyosalpinx he considers draining from below good practice. More patience and persistence in therapeutic measures were urged before final resort to operation.

Dr. Wharton Sinkler, of Philadelphia, Co-referee, expressed the view that pyosalpinx and other inflammations constituted the typical indication for the removal of the tubes and ovaries.

Nervous symptoms, like those constantly observed at the menopause, are not infrequent after oöphorectomy. Insanity in some form occasionally seems to depend upon this operation. The immediate result of the operation is satisfactory; but in the cases of operation for nervous symptoms relapse is common. In the cases in which insanity occurs only at the menstrual period operation may be expected to do much good. Following operation for diseased appendages, improvement in the general health and in flesh usually occurs.

Dr. J. J. Putnam, of Boston, presented the views of Boston surgeons concerning removal of the ovaries and tubes. Of 24 cases referred to, in which the organs were but little diseased, the operation being performed largely for nervous symptoms, 8 were reported as benefited, 11 not benefited, and 2 others died of other causes. In some cases favorable results followed operation; in one instance, a woman addicted to the morphine habit, acquired by taking the drug for pain, was entirely cured after operation.

Dr. S. Weir Mitchell, of Philadelphia, expressed the need for more complete statistics. The careful operators, whose work had been referred to in the papers, did not perform all of the operations. It was from the cases treated by the young and inexperienced that he thought impressive lessons might be learned. Dr. Mitchell thinks that ten, fifteen, or twenty years should elapse before finally deciding the remote effects of the operation. He strongly urges observation for some time before operation, and even consultation before recourse is had to surgical measures. The practical abolition of the death-penalty in surgery, he feared, led to operations without proper consideration.

Dr. Gairdner, of Glasgow, related an interesting case in a young single woman, who for a long time suffered the most excruciating pelvic pains, for which she sought medical advice. As this was before the day of pelvic surgery, other measures were employed. It was symptomatically, however, just such a case as oöphorectomy is now done for. The patient married when twenty-five years old, and in a few months became pregnant, when all pain disappeared and never returned.

Dr. Lee, of New York, does not counsel operation

for nervous symptoms; but permanent structural disease of the appendages, when once diagnosticated, is, to his mind, a positive indication for surgical interference.

DR. GAIRDNER keeps up correspondence with his cases for from five to eight years, and in no case has he had cause to regret having operated.

DR. WALTHAM, of Louisville, could not conceive of any condition justifying normal ovariotomy. He considered laparotomy at times a conservative operation.

DR. JAMES STEWART, of Montreal, followed with a paper on "Nerve-stretching in Inveterate Cases of Trigeminal Neuralgia." He confined his observations to those inveterate cases commonly called epileptiform.

Three cases were reported from his own observation free from pain for thirteen, twelve, and four months respectively after operation. He was able to collect from the literature only eleven other cases that had been reported nine months or later after operation.

The results of neurectomy are more permanent than those of stretching. Stretching is a mild operation, and may be repeated several times before resorting to neurectomy or ligation of the common carotid. If the neuralgia is general, several branches of the nerve should be stretched.

DR. FRANCIS DELAFIELD, of New York, read a paper on "The Diseases of the Kidneys Popularly Called 'Bright's Disease,'" which will be published in the October number of *The American Journal of the Medical Sciences*. The following is a brief *résumé*.

The time has fully come to abandon the idea that there is such a disease as Bright's disease, and to cease in the attempt to describe varieties of a disease that does not exist.

The different forms of kidney disease that are commonly included under the name of Bright's disease can all be conveniently classified under the heads of: Congestion of the kidney; degeneration of the kidney; inflammation of the kidney.

Acute congestion of the kidneys is produced by the ingestion of poisons, by extirpation of one kidney, by injuries, by surgical operations, and by unknown causes.

Chronic congestion of the kidneys is produced by some long-continued mechanical interference with the circulation of the blood, an interference that necessarily causes congestion of other parts of the body as well as of the kidneys. The characteristic changes in the kidneys are: Swelling or flattening of the epithelium of the cortical tubes, dilatation and thickening of the capillaries of the glomeruli, congestion and dilation of the pyramidal veins.

Degeneration of the kidneys is always a secondary process induced by the introduction into the body of inorganic poisons or of the poisons of the infectious diseases, or by the effect produced on the body by chronic diseases or vicious modes of life, or by disturbances of the circulation. *Acute degeneration of the kidneys* is almost constantly found with the infectious diseases and with poisoning by arsenic, phosphorus and mercury. Acute degeneration, therefore, includes a well-defined set of cases, definite in their lesions, their causes, their symptoms, and evidently not likely to be influenced by any treatment. *Chronic degeneration of the kidneys* is produced by the same mechanical causes as those that produce chronic congestion, by chronic alcoholism and by vicious modes of life. It is, therefore, always a secondary lesion.

The inflammations of the kidneys are naturally subdivided into: Acute exudative nephritis; acute productive or diffuse nephritis; chronic productive or diffuse nephritis with exudation; chronic productive or diffuse nephritis without exudation; suppurative nephritis; tuberculous nephritis.

Acute exudative nephritis is an acute inflammation of the kidneys, characterized by congestion, an exudation of plasma, an emigration of white blood-cells, and a diapedesis of red blood-cells from the vessels; to which may be added swelling or necrosis of the renal epithelium and changes in the glomeruli. Of such a nephritis we may distinguish three varieties:

1. A mild form, which occasions symptoms during life, but leaves no lesions in the kidneys after death.

2. A more severe form, in which we find inflammatory changes in the kidneys after death.

3. A form characterized by the excessive production of pus-cells.

In the mild cases we find no decided lesions in the kidneys after death. In the more severe cases the kidneys are increased in size, their surfaces are smooth, the cortical portion is thick and white, or white mottled with red, or the entire kidney is intensely congested. Such conditions are characterized by the evidences of exudative inflammation in the tubes, stroma, and glomeruli.

As to *etiology*, acute exudative nephritis is frequently a primary disease, occurring either after exposure to cold, or without discoverable cause. It complicates infectious diseases and severe inflammations. The urine is diminished in quantity; its specific gravity is apt to be high; it contains albumin in considerable quantity, hyaline and granular tube-casts, blood-cells and epithelial cells.

Acute productive or acute diffuse nephritis is one of the forms of scarlatinal nephritis; it occurs early and late in the course of diphtheria; it is the most important variety of the nephritis of pregnancy, and it is especially frequent as a primary nephritis with or without a history of exposure to cold. During the acute periods of the nephritis the urine is scanty, colored by blood, of high specific gravity. It contains much albumin, numerous casts of all kinds, and red and white blood-cells.

Chronic productive or diffuse nephritis with exudation frequently occurs as a primary disease, especially in young adults. It follows acute diffuse nephritis, chronic congestion and chronic degeneration of the kidney. It may complicate syphilis, chronic phthisis, chronic endocarditis, prolonged suppuration, and chronic inflammation of the bones and joints. The urine varies in quantity at different times. The specific gravity and the proportion of urea to the ounce of urine slowly diminishes. In the cases of shorter duration the specific gravity is apt to run between 1.012 and 1.020. In the very chronic cases it will be between 1.001 and 1.005. The urine contains albumin and casts.

In *chronic diffuse nephritis without exudation* the urine is increased in quantity, of a specific gravity of about 1.010, containing a diminished quantity of urea, without albumin or casts, or with a trace of albumin and few casts, except during exacerbations of the nephritis, when the quantity of albumin and the number of casts may be considerable.

Acute congestion of the kidneys can be relieved by the application of heat to the surface of the body. Chronic congestion is best managed by the drugs that stimulate the heart and dilate the arteries. We evidently have no means at our command by which we can influence acute degeneration of the renal epithelium. Chronic degeneration also seems to be a condition that we are unable to treat.

In acute exudative and in acute diffuse nephritis the main indications for treatment are to diminish the severity of the nephritis and to regulate the circulation. To diminish the severity of the nephritis we employ cups over the lumbar region, heat over the lumbar region or over the entire body, and the internal use of calomel, sulphate of magnesia, opium, aconite, or digitalis.

The disturbances of the circulation are largely the causes of the cerebral symptoms and of the dropsy. With a laboring heart and contracted arteries we employ the drugs that dilate the arteries—chloral hydrate, opium, nitrite of amyl, and nitroglycerin—or we diminish the quantity of the blood by venesection, sweating or purging. With a feeble heart and relaxed arteries we use the cardiac stimulants.

In chronic nephritis climate and mode of life constitute the important parts of the treatment; it is doubtful if drugs exert any effect on the nephritis. A warm, dry climate and an out-of-door life are of the greatest importance. Medical treatment can, however, be employed with advantage for the anemia, the dropsy, and the disturbance of circulation.

DR. ANDREW H. SMITH, of New York, read a short paper, expressing belief that albumin is a transition-substance, capable of existing in several different forms. In a series of experiments he boiled a solution of serum-albumin, and removed the precipitate by filtration. Nitric acid was added to the filtrate and again the mixture was filtered. Precipitates were further produced by the addition of bichloride of mercury, ether and chloroform, thus showing that no one reagent removed all of the albumin.

DR. VAUGHAN, of Ann Arbor, in testing urine for albumin, depends solely upon heat and nitric acid, separately and combined, and acetic acid, with ferrocyanide of potassium, and does not consider the other reagents reliable.

THIRD DAY—SEPTEMBER 24TH.

A Discussion upon the Relations between Arterial Disease and Visceral Changes was opened by DR. GEORGE L. PEABODY, of New York, Referee. He confined himself to the consideration of arterio-sclerosis. The cause of the disease is a general defect of nutrition, with such special etiological factors as heredity, syphilis, alcoholism, old age, etc.

According to the view of Thoma as to the cause of arterio-sclerosis, the muscular coat of the artery loses tone, as a result of which the vessel dilates. The blood-current then becomes slower. To compensate for the dilatation of the vessel, a new growth occurs in the intima, which may almost occlude the artery. This is the only lesion that Dr. Peabody has succeeded in finding in a number of cases of angina pectoris examined. One of the first evidences of the disease is seen in the eye-ground. The vessels elongate, as shown by their greater tortuosity. The carotids and their branches at times seem to be the first to be affected.

DR. W. T. COUNCILMAN, of Baltimore, Co-referee, reported the result of a study of some forty cases of arterial and visceral disease at the Johns Hopkins Hospital. He believed, with Dr. Peabody, that the disease originates in the muscular coat of the arteries.

In the discussion, DR. ORD, of London, expressed the belief that the disease was a general one, affecting the whole system, and possibly in some way connected with gout. Gout being such a common affection in London, he had had opportunity to see many cases of the disease under discussion.

DR. GAIRDNER, of London, discussed the relation of the disease to aneurism.

DR. R. H. FITZ, of Boston, read a paper on "Intestinal Perforation in Typhoid Fever: its Prognosis and Treatment." The writer said that this complication is found in about 1 per cent. of all cases of typhoid fever, and is the cause of death in somewhat more than 6 per cent. of the fatal cases. It rarely occurs in children, and is twice as frequent in man as in woman. It is present in the small intestine in more than four-fifths of the cases, and usually proves fatal during the first week after its occurrence. It takes place in mild or in severe cases, and its symptoms may be absent or latent, gradual or severe.

Differences of opinion concerning its prognosis have existed for many years, and are based upon a lack of agreement as to the significance of the symptoms. Though these are often called characteristic, they give evidence only of a peritonitis, general or circumscribed. This may, in typhoid fever, result from a variety of causes, and fatal perforation may occur without any symptoms suggesting its presence.

In most cases of recovery from symptoms of perforation of the bowel in typhoid fever an attack of appendicitis is closest simulated, while in the great majority of the fatal cases other parts of the bowel than the appendix are perforated. It is probable that the appendix is more often inflamed and perforated in typhoid fever than has hitherto been suspected.

In typhoid fever the prognosis of apparent perforation of the bowel is to be regarded as the more favorable the more closely the symptoms and their course resemble those of appendicitis.

In the treatment of this complication early laparotomy is reported to have been tried in ten cases, with but one successful result; while of twenty-seven cases of circumscribed peritonitis in typhoid fever, largely attributed to intestinal perforation, three recovered after incision, seventeen after resolution, and nine after the spontaneous discharge of pus.

It is recommended that immediate laparotomy be employed for the relief of suspected intestinal perforations in typhoid fever only in the milder cases of this disease. In all others evidence of a circumscribed peritonitis should be awaited, and may be expected in the course of a few days. Surgical relief of this condition should then be urged as soon as the patient's strength will warrant.

In the discussion, DR. J. M. DA COSTA, of Philadelphia, stated that he had recently met with two cases of intestinal perforation in typhoid fever, in which opera-

tion was performed in one within six hours after the first symptom. The patient seemed to do well at first, but died some twenty-six hours later.

In the second case an operation was not performed until thirty-six hours after the perforation. This patient also perished.

Dr. Da Costa would not advise operation for perforation. In cases, however, in which perforation has occurred and the peritonitis has been localized by adhesive inflammation, and the patient should live, an operation could be performed later for the peritonitis. Should general peritonitis follow perforation, any means of treatment must prove futile.

DR. WILLIAM PEPPER, of Philadelphia, was particularly struck by the number of cases of recovery after perforation reported in medical literature. He feared that in some of these cases a mistake in the diagnosis had been made. He was reminded of three cases in which he had recently been asked to see patients in the third week of typhoid fever, all of whom proved to be suffering from appendicitis.

DR. HENRY P. WALCOTT, of Cambridge, read an interesting paper on "The Relation of Drinking-water to Disease," in which he pointed out that neither the appearance nor the taste of water is to be relied upon as indicative of purity or impurity. Even chemical analysis may often fail to detect serious objections in water. Dr. Walcott believes that it is either living organisms or their products that are most harmful.

The last paper of the day was "A Contribution to the Pathology of Pernicious Anemia," by DR. J. P. CROZIER GRIFFITH and DR. CHARLES W. BURR, of Philadelphia.

A new classification of the anemias, upon a more scientific basis, was proposed.

DRS. GRIFFITH and BURR have found that by treating with ferrocyanide of potassium sections of the liver from cases of pernicious anemia the blue reaction characteristic of iron is produced. This reaction was wanting in all other cases.

For purposes of comparison the organs of patients dead of other forms of anemia were examined, and in each case the distinct difference from pernicious anemia was demonstrated.

For this reason, as well as on account of the other characteristics of the affection, they classify pernicious anemia as a distinct anemia.

Experiments upon animals are still being made, which being incomplete, were not reported at this time.

(To be continued.)

AMERICAN ASSOCIATION OF ANDROLOGY AND SYPHILOLOGY.

First Annual Meeting, held at Washington, September 22, 23, 24, and 25, 1891.

FIRST DAY—SEPTEMBER 22D.

The proceedings were opened by a paper on "Reflex Irritations and Neuroses Caused by Stricture of the Urethra in the Female," by DR. FESSENDEN N. OTIS, of New York, in the absence of whom the paper was read by his son, DR. W. K. OTIS. Stricture of the urethra in the female is rarely considered or even referred to in works on the general diseases of females, or on the special diseases of the genito-urinary organs of the female. From this it might be inferred that the difficulty is so rare or unimportant as to be of little consequence. Symptoms in the female that in the male would at once be accepted as indicating the probable presence of urethral stricture are often referred to under the title of "irritable bladder," and attributed to causes quite independent of their possible relations to the urethra. The fact that stricture of the male urethra is accepted as usually due to either gonorrheal inflammation or to some traumatic cause, while the "irritable bladder" in the female occurs quite independently of any previously recognized inflammation or injury, tends doubtless to prevent the consideration of stricture as a possible cause of the trouble. In regard to the origin of organic urethral strictures, in either male or female, Dr. Otis is thoroughly convinced that the largest proportion depended upon cicatricial deposits due to lithiasis, at periods often long antecedent to the gonorrhea to which they are attributed. The histories were given of four cases of stricture of the urethra in the female, causing reflex troubles as varied and severe as those occasionally caused by stricture of the urethra in man. Relief was afforded by removal of the strictures. The desirability of early exploration of the urethra by means of the urethrometer or the bulbous sound was suggested, in order to promptly eliminate at least one important element of failure in the diagnosis and treatment of such cases.

DR. ROBERT W. TAYLOR, of New York, read a paper on "Genital Chancres in Women." He stated that while chancres of the genital organs were common in both sexes, extra-genital chancres were more common in women than in men. In women they are more irregular in their course and are often small and ephemeral, so that their nature is not suspected. For clinical purposes, Dr. Taylor classed genital chancres in women as follows:

First. The superficial or chancrous erosion, which appears first on the mucous membrane, and is liable to be mistaken for a ruptured herpetic vesicle or an abrasion. It is benign in appearance, and begins as a red spot somewhat deeper in color than the mucous surface on which it is seated. It has but a short period of existence and frequently comes and goes without the knowledge of its bearer. Second. The scaling papule or tubercle, which is found upon the outer surface of the labia majora, upon the labia minora, upon the prepuce of the clitoris, upon the internal surface of the thighs, the inguinal folds and the hypogastrium. It begins as a small, dull-red papule, and when irritated it loses its epidermal covering and becomes raw and exuding. All chancres of this variety are slow in disappearing. Third. The elevated papule, which presents the appearance of a small, well-circumscribed, flat or elevated lesion, the surface of which is similar to that of the chancrous erosion. It is seen in its most typical form upon the mucous membrane of the labia majora and minora. It may become much hypertrophied and around it may develop a greater or less degree of indurating edema. It rarely shows marked induration. Fourth. The encrusted chancre, which is not uncommonly found upon the pudendal cutaneous surfaces, and indeed upon

any portion of the integument. Encrusted chancres are said not to be found within the area of the mucous membrane of the vulva, but it is not uncommon to find chancres in an encrusted state at the fourchette, and they are rarely found upon the clitoris and the labia minora. Rarely the chancre called by Fournier *chancre multicolore*, or the *chancre en cocarde* is found, in which the surface of the chancre presents a series of concentric zones of different colors. Fifth. The indurated nodule, which is rare in women, although common in men. In men the syphilitic neoplasm is, as a rule, circumscribed and compact; in women it tends to diffuse itself more loosely into the soft mucous tissues. Sixth. The diffuse exulcerated chancre, which is not infrequently observed in women of the lower order, who are uncleanly in their habits and intemperate. It presumably begins as a chancrous erosion. This form of chancre sometimes looks like raw beef, and at other times like an elephantine encrusted chancre.

As a rule, chancres in the female are unaccompanied with pain. Chancres of the vagina are rare.

In reply to an inquiry by Dr. Edward R. Palmer, of Louisville, Ky., as to whether chancres were more common on the upper or the lower lip, Dr. Taylor stated that it was a matter of chance. Of the labial chancres that had come under his observation, probably 60 per cent. had been of the lower lip.

Dr. J. Blake White, of New York, presented some "Observations upon the Syphilitic Cachexia." He stated that although syphilis has for centuries been a familiar disease, the essential nature of the poison still remains undiscovered. Specific diseases ordinarily exhibit a peculiar affinity for certain tissues and organs of the body, but after the initial manifestation of syphilis and its accompanying adenopathy, every structure of the body may become attacked, and if it is not checked in its inception a host of consecutive ills may ensue; the unfortunate sufferer cannot hope for spontaneons resolution, as occurs in many other maladies. Certain temperaments are less prone than others to put on the cachectic livery of the disease, but experience tends rather to prove that no particular temperament enjoys an absolute immunity from it. Patients suffering from any form of scrofula or tuberculosis, or whose kidneys are diseased at the time of infection, suffer most severely from the consecutive accidents of syphilis. In such cases it becomes necessary to use tonics and to have recourse to remedies that also act through the glandular system. The therapeutic value of the salts of gold in the cachexia of syphilis has been strongly advanced. A combination of the salts of gold with those of manganese in tuberculous and syphilitic affections has proved an especially advantageous remedy. The salts of platinum may be substituted for those of gold. The salts can be combined in fluid form and administered hypodermatically, glycerin being used as a solvent.

Dr. John A. Fordyce, of New York, read a paper on "The Occurrence of Nephritis in Syphilis." He said that the occurrence of albuminuria, with or without edema, has not infrequently been observed early in the course of syphilitic manifestations. Cases had come under his observation in which the albuminuria had disappeared under the influence of mercury. This transient albuminuria is comparable with other congestive phenomena that take place in internal organs during the early period of this disease, or with the albuminuria that so frequently complicates acute infectious diseases. In addition to this transient albuminuria in early syphilis, and the more serious amyloid, gummatous, and interstitial nephritides, a number of observers have noted the occurrence of an acute parenchymatous nephritis, pursuing a course not unlike the nephritis of scarlatina, at times terminating in recovery and again passing into a chronic form.

Dr. Taylor took exception to the statement that Nature does not eliminate the poison of syphilis. Syphilis is often aborted during the first or second stage. Animals are immune to syphilis, and some persons seem to possess the same immunity. Clinical evidence goes to show that syphilis sometimes does abort spontaneously. To those who suffer decidedly from the syphilitic cachexia should be added tall, thin persons, flabby individuals, and persons with light-red complexions.

Dr. Taylor stated that transient albuminuria was common during the earlier stages of syphilis. Casts are rare, but when found they are usually of the hyaline character.

Dr. J. Nevins Hyde, of Chicago, indorsed what Dr. Taylor said about the immunity of certain persons against syphilitic infection. A number of such cases had come under his personal observation in which no symptoms had appeared after a lapse of many years.

Dr. James P. Tuttle, of New York, stated that eighteen months ago a man came under his observation with a typical papular indurated chancre. Two weeks afterward he brought his wife, who had become infected, and about six or seven weeks later his mistress, who at that time had an erosive chancre. All received no treatment until the secondary symptoms appeared. The man suffered from these symptoms in their most virulent form; the wife developed them in a milder degree, while the mistress has yet never had a single symptom.

Second Day—September 23d.

Dr. Edward L. Keyes, of New York, opened the session by reading a report of "A Case of Excision of Stricture and Urethroplasty for Radical Cure." He stated that the radical cure of stricture of the deep urethra is still an unsettled question. For the anterior urethra the question has been measurably solved through the zeal and energy of Dr. Otis, of New York, by his persistent advocacy of extensive dilating urethrotomy. The same solution has not yet been made applicable in the case of organic strictures of the deep urethra, nor has any other single rule been advanced to cover all cases. Dr. Keyes classified deep organic strictures into three groups, namely: the soft, the cicatricial, and the nodular. The soft stricture is not uncommon; it can be recognized by a peculiar sensation in the passage of the instrument, and can be permanently cured by continued dilatation. The history of a case of radical cure of a deep urethral stricture, complicated by perineal fistulæ, and by considerable nodular tissue, was detailed. The stricture was first laid open upon a filiform guide, and the dense fibrous tissue composing it cut out; the fistulous tracts were also dissected out and a plastic operation was performed, a large flap being taken from the inner

layer of the prepuce for that purpose. This piece of tissue was first thoroughly disinfected and then sutured into place in the gap left by the excised stricture. The perineal wound healed rapidly and recovery was uninterrupted.

MR. REGINALD HARRISON, of London, stated that while his experience with this class of cases was limited, he thought that the method of treatment was valuable in deep urethral strictures. While in Paris during the past summer he had seen M. Guion treat a number of cases of traumatic stricture by excision. Instead of doing a plastic operation, however, M. Guion had closed the perineal wound by three layers of sutures.

DR. ARTHUR T. CABOT, of Boston, read a paper entitled "A Contribution to the Surgical Treatment of Ruptures of the Bladder," in which he considered the conditions of extra-peritoneal rupture of the bladder. The usual symptoms of rupture of the bladder were tolerably distinct, and in most cases the lesion can be demonstrated beyond doubt by the injection of air or fluid. This test sometimes fails when the rent is small, or when there is a valvular closure of the bladder-wound. Some authorities advise that cases of extra-peritoneal rupture should be treated by simple drainage of the bladder, either through a perineal wound or by a retained catheter. Dr. Cabot considers that this plan affords insufficient drainage for the urine that has already escaped into the tissues, or for the pus and masses of sloughing tissue following contact with the urine.

It is important for the operator to know where the rent in the bladder-wall is situated, and in what direction the urine is forcing its way into the loose perivesical connective tissue. When this knowledge is obtained, he can make an opening into the extravasation from the nearest available point on the surface, and establish the most direct drainage possible. An incision into the prevesical space, as suggested by Mr. Rivington, is only applicable in cases in which the rupture is in the front wall of the bladder and in which the effusion is slight. Another plan proposed in doubtful cases is to perform median cystotomy, and with the finger in the bladder to search for the rents, but this method has in some instances proved unsuccessful. In uncertain cases of extra-peritoneal rupture the best method of obtaining a knowledge of the condition of things is to open the abdominal cavity, thus getting an opportunity to thoroughly inspect and palpate the parts about the bladder. Dr. Cabot then related the history of a case in which an extra-peritoneal rupture of the bladder occurred during the operation of litholapaxy, which was at once discovered and treated by opening the abdomen. He suggested that in all cases in which a rupture is made out, immediate action should be taken, and laparotomy performed, excepting when it is evident that the urine is extravasated into the prevesical space—when a supra-pubic incision is sufficient—or in cases in which the patient's condition is such that he cannot bear more than the median operation.

SIR WILLIAM MACCORMAC, of London, stated that in many cases the diagnosis of intra-peritoneal ruptures of the bladder was easier than that of extra-peritoneal ruptures. A point of diagnosis mentioned in the text-books on the subject, namely, extreme shock, he failed to find in two cases under his observation.

DR. L. BOLTON BANGS, of New York, stated that the cystoscope might be employed in locating rents in the bladder.

DR. KEYES stated that it was impracticable to employ the cystoscope in these cases, on account of the bleeding.

DR. CABOT called attention to the fact that the ruptured bladder would be collapsed, and so not be suitable for the employment of the cytoscope.

DR. JOHN P. BRYSON, of St. Louis, read a paper on "The Use of Salicylic Acid in the Treatment of Certain Forms of Cystitis," in which he related that about three years ago a student by mistake mixed an ounce of a 2 per cent. solution of salicylic acid in glycerin with five ounces of water for the purpose of washing out the bladder of a patient with chronic exudative cystitis, who had previously had his bladder irrigated with the standard borax solution without material benefit. The returning fluid was milky in appearance, and a second injection was made before the mistake was discovered. The patient returned the next day, and reported that he was much better, and requested that a similar injection be again given, which was done. Since then, in similar cases, a salicylic acid solution has been in common use at the genito-urinary clinic of the St. Louis College, and marked benefit has been obtained from it. It is especially useful in the more chronic cases, in which the surface of the bladder is covered with a thick or a tenacious protection, made up of mucus and necrotic epithelium. Salicylic acid has the power of dissolving or loosening the epithelial cells, and the bladder is then in a proper condition for the use of other remedies. The use of the salicylic acid solution is not of equal service in all cases of cystitis, and is distinctly contra-indicated in some. In acute cystitis, with thin exudation, it is not called for. Where there is ulceration, with a disposition to bleed, it is harmful. It is also harmful in tuberculous disease, and in old cases of prostatic disease, with sacculated bladders.

DR. EDWARD R. PALMER, of Louisville, stated that Dr. Bryson had mentioned this incident to him a year ago in Altoona, and that since then he has had considerable favorable experience with the use of salicylic acid as an injection in cystitis. He wished to state, however, that in using Thiersch's solution, which is a combination of salicylic and boric acids, his patients often complained of severe pain.

DR. L. BOLTON BANGS, of New York, stated that he was grateful to Dr. Bryson for reporting this method of cleaning out the bladder. His experience with the use of Thiersch's solution was similar to that of Dr. Palmer. He supposed the strength of the solution is somewhat a matter of judgment.

DR. JAMES P. TUTTLE, of New York, said that he had used Thiersch's solution for the past three or four years for irrigating the bladder, and he desired to thank Dr. Bryson for telling him why he had such good results in those cases.

DR. WILLIAM H. HINGSTON, of Montreal, read a paper on "Undetected Stone," in which he dwelt upon the difficulty sometimes experienced in locating a stone in the bladder. The most careful exploration may fail to reveal its presence. In examination for stone the bladder should be partially filled, and the patient can be

made to empty it during the exploration, with the hope that the calculus (if there be any) will strike against the instrument. The slight difference in specific gravity between the calculus and the turbid fluid contents of the bladder allows the stone to float about, and in that condition the sound or searcher does not elicit the characteristic "click" sought for.

DR. EDWARD L. KEYES, of New York, noted that Dr. Hingston had not alluded to the washing-bottle and the small tube for the purpose of detecting stone. Another method is educating the finger to appreciate the gritty feeling—even more important than the "click."

DR. L. BOLTON BANGS, of New York, said that he was in some cases enabled to detect stone in the bladder by means of the cystoscope.

DR. EDWARD L. KEYES, of New York, read "A Note Upon a Possible Service to be Expected from Diuretin in Genito-urinary Surgery," which will be published in full in a subsequent number of THE MEDICAL NEWS.

A paper on "Encysted Stone, Complicated with Growths of the Bladder," by DR. C. H. MASTIN, of Mobile, was read by the Secretary. The history of a case in which a growth was spontaneously expelled from the bladder eleven days after operation was detailed, and the specimens were exhibited.

(To be continued.)

AMERICAN ORTHOPEDIC ASSOCIATION.

Fifth Annual Meeting, held at Washington, September 22, 23, 24, and 25, 1891.

FIRST DAY—SEPTEMBER 22D.

THE session was opened by DR. A. B. JUDSON, of New York, who delivered the President's Address, choosing as his subject, "Orthopedic Surgery as a Specialty." He said that in a Congress chiefly composed of special societies, it was proper to ask why orthopedic surgery exists and thrives as a specialty. He believed it was because orthopedic patients do not, as a rule, make absolute recoveries. There is commonly a residuum of disability and deformity, and general practitioners concur with the public in referring such cases to experts. Orthopedic patients are generally children, and in the slow methods of this specialty great disability and deformity may be avoided by continuous treatment, during which the affected part increases in ability and symmetry with the growth of the child. This is especially the domain of physical demonstration, where subjective symptoms are forgotten in view of objective signs, where diagnosis depends on what can be seen, touched, and measured, where treatment is by physical forces under direct control, and where results are recorded in degrees of an inch and fractions of an inch. Dealing thus with physical realities let us not overlook the moral verities, remembering that diligence is the price of success, and that the only desirable success is to be reached by rejecting error and cleaving to what is true.

DR. W. R. TOWNSEND, of New York, read a short paper on "Uniform Nomenclature in Orthopedic Surgery." While it was not his wish to establish a new school of pathology or to coin new names for the pathological conditions of orthopedic surgery, he felt that as far as possible it was desirable to prevent the designation of one disease by numerous appellations. Thus, for instance, in the various hospitals of New York, hip-joint disease is known by seven different names. Dr. Townsend believes that if a uniform nomenclature were established, a uniform system of taking measurements and clinical histories will speedily follow.

On motion of DR. VANCE, of Louisville, a committee of three was appointed to consider the means of adopting some system of nomenclature that would tend to produce uniformity in this respect.

DR. HENRY LING TAYLOR, of New York City, read a paper entitled "Two Cases of a Peculiar Type of Primary Crural Asymmetry."

In the first case, that of a lady twenty-three years of age, there was a difference of two inches in favor of the left side, measuring from the anterior superior spine of the ilium to the internal malleolus. Measuring from the head of the tibia to the internal malleolus, the left leg was one and one-eighth inches longer than its mate. In the other case, in a girl of fifteen years, the left leg was one inch shorter than the right. Here, also, rather more than half the shortening was shown to be below the knee.

The peculiarity of these cases consisted in the greater size and strength of the shorter limb, of which one of the patients at least was conscious, and which was plainly demonstrated in both. In neither case was there any lesion or impairment of the nervous, muscular or osseous system beyond the unequal development, and in neither case did true lateral curvature exist.

DR. H. AUGUSTUS WILSON, of Philadelphia, reported a case of "Spina Bifida with Partial Motor and Sensory Paralysis of Both Extremities, Complete Paralysis of the Bladder and Rectum, Double Equino-varus and Purulent Bursitis."

The case was that of a colored girl, four years old, of robust appearance, an only child of healthy parents, born at full term, without a diathetic hereditary history.

The spina bifida was in the lumbo-sacral region and the pedicle measured six and one-half inches in circumference. The tumor was hard and dense except in one spot, about a half-inch in diameter, where the covering was extremely thin and the contents oozed on pressure and when the child cried. There were incontinence of urine and involuntary evacuations from the bowels, due to paralysis of the sphincters.

The flexor and extensor muscles of both legs below the knees were paralyzed and the electro-muscular contractility could scarcely be perceived. There was complete anesthesia of the right foot, ankle, and calf on the right side, also present, although less marked, on the left. There was extreme double equino-varus which firmly resisted manipulative correction. On both feet there were suppurating bursæ under the distal extremities of the malleoli upon which the child stood in her attempts to assume the erect posture. Abscesses developed in the labia majora. Attempts made to arrest the suppurating bursitis by incision and the application of chemical antiseptics were followed by a persistent refusal of the incised parts to cicatrize and with no perceptible cessation of the suppuration. This failure of incised wounds to heal contra-indicated surgical attempts at correction of the equino-varus, and mechanical efforts were followed by tumefaction and threatened suppuration at the points

where pressure was necessary, and these were, therefore, also abandoned.

Preliminary puncture of the spina bifida, as recommended by James Morton, prior to injection, was followed by convulsions. The child is still living in a hopeless condition.

DR. T. M. L. CHRYSTIE, of New York, read a paper on "Congenital Club-foot, with Absence of the Great Toe and Contiguous Bones of the Instep," which will appear in full in a later issue of THE MEDICAL NEWS.

DR. WILLIAM E. WIRT, of Cleveland, Ohio, reported a case of "Double Club-foot, Double Club-hand, and Multiple Deformities," the complete text of which will be published in a subsequent number of THE MEDICAL NEWS.

DR. JOHN C. SCHAPPS, of Brooklyn, read a paper on "Mechanical Treatment after Excision of the Knee." The treatment after knee-joint excision is usually lightly passed over by authorities as simply that of compound fracture. But immobilization for a few weeks frequently fails to secure firm bony support from pelvis to ankle. The two cases reported are typical of a large class. They were in boys, respectively fifteen and seven years of age. Only a thin slice was removed from each epiphysis, and very slight flexion was allowed. Union was immediate, without suppuration. After fixation had been maintained for four months a marked degree of flexion took place. This was without recurrence of the disease. At the end of eighteen and ten months respectively after the excision by means of the osteoclast, the limbs were restored without fracture. One relapsed as late as a year and a half after the excision, but the deformity was again corrected by means of a brace. In both, union ultimately became firm with the limb in a nearly straight position.

In these cases the result of the operation was a mass of soft cancellous tissue in length nearly double that of a single epiphysis. In it were inserted at an obtuse angle two long levers, the action of which served to increase the flexion already existing. As the epiphyseal mass subsequently became firm enough to bear the increased weight still transmitted at a mechanical disadvantage, the soft condition must have been due to the congestion that disappeared after the necrotic focus had been removed. The possibility of subsequent deformity should not be allowed to weigh too heavily against excision. If the limb is put up perfectly straight and support is continued for a sufficiently long time (always less than that required by purely mechanical methods of treatment), the danger of deformity is slight. If it occur, it may be corrected within a liberal margin of time. While the operation is not always the short cut to a cure that it has been claimed to be, it has two important advantages: it abolishes at once the traumatism of motion, and removes the tuberculous focus that is always a menace to the patient's life.

In the discussion, DR. PHELPS expressed the belief that the relapses that are so frequent in these cases are due to operating on growing limbs in children under ten years of age. He claims that the limb should be placed in a straight or over-flexed position. Resection of the hamstring tendons, with the wearing of a proper apparatus, is necessary. He would not perform excision in a child under ten years of age, but in such a case would prefer scraping.

DR. HOFFA did not agree with Dr. Phelps. He believes the relapse to be due to a failure to remove all the diseased tissues. He considers it perfectly proper to perform resection in children. He regards the shortening of the limb as due not to the excision, but to the disease itself, and considers the flexion as the result of an atrophy of the extensor muscles.

DR. GRIFFITHS, of Kansas City, does not cut the hamstring tendons, but carefully removes all of the diseased portions, preserving, if possible, the inelastic patellar ligament and the extensor femoris. He urges the importance of this preservation of the inelastic tissue, and its connection with the quadriceps femoris.

DR. A. J. STEELE, of St. Louis, read a paper on "The Orthopedic Work of the Late Mr. Thomas." Mr. Thomas was a corresponding member of the Association. Dr. Steele eulogized his skill and devotion to work. Founding his belief on the inflammatory nature of joint-disease, Mr. Thomas was an earnest advocate of thorough immobilization of the joint, with the removal of all pressure. He was strongly opposed to traction, claiming that no advantage resulted and much injury was done. Dr. Steele, however, regarded traction as of great service, especially in the earlier stages of the disease.

DR. A. M. PHELPS, of New York City, exhibited "Some Lateral Traction Fixation Hip-splints." He believes that spasm of the muscles is always present in morbus coxarius, and that this results in an aggravation of the diseased condition. Hence the necessity for some method of immobilization of the joint. The joint should be fixed until perfectly cured, whether for a few months only or for a year. Ankylosis does not follow prolonged immobilization, but is due to pathological processes in the joint. Atrophy of the muscles, however, will follow. In the treatment of joint-inflammation rest is the most important law, as it is of all inflamed tissues. Traction should be made not only in the line of the shaft of the bone, but laterally in the line of the axis of the neck.

DR. VANCE believed that the treatment of hip-joint disease depends as much on the constitutional condition and hygienic surroundings of the patient as on the use of splints.

DR. SAYRE stated that only in rare instances does he find it necessary to employ lateral extension. He believes that in cases of fibrous ankylosis much good can be accomplished by judicious passive motion. But if pain and tenderness persist for over twenty-four hours after such motion, harm has been done.

The paper of MR. B. E. BRODHURST, of London, upon "Gonorrheal Rheumatism and Its Treatment, Primary and Secondary," was read by DR. RIDLON. It dealt with the causes, varieties, pathology and treatment of gonorrheal joint-inflammation, more particularly the inflammation occurring in the larger joints resulting in ankylosis. Several interesting cases were reported. Reference was made to the treatment of ankylosis by forcible extension under anesthesia, tenotomy being employed when necessary. In this manner Mr. Brodhurst had operated upon over 1000 cases of fibrous ankylosis, in none of which had an accident of any kind occurred.

DR. E. G. BRACKETT read an interesting and instructive paper upon "Atrophy in Joint-disease." He noted that in all cases of joint-disease, atrophy occurs,

of varying degree, and not directly proportional to the severity or duration of the disease. The leg is nearly uniformly involved throughout. The atrophy is usually ascribed to the direct influence of the diseased joint on the nutrition, through the nerves.

Dr. Brackett maintained that this theory does not explain the condition, because of the variation in its occurrence and the uniform distribution over the whole leg. If due to a reflex influence from the diseased part the degree of atrophy should bear a relation to the character of the disease—which it does not. It should also more particularly affect that portion of the limb diseased; but the whole leg is nearly uniformly involved. An analogous result is seen later in the lack of development, which is proportional to the degree of freedom given the limb, and involves all parts equally, as would be expected from a physiological defect of nutrition.

It must be concluded that the degree of atrophy in joint-disease is chiefly determined by the degree of use. Atrophy occurs in other conditions not arising from disease, but occasioning restriction of function.

This atrophy is uniformly distributed over the entire limb. The lack of development is also uniformly distributed, and is proportionate to the freedom that the limb has been allowed.

In the discussion that followed, the theory of atrophy from disease was opposed by DR. YOUNG, of Philadelphia, who held that in joint-disease the reflex tetanoid spasm that occurs so early and persistently throughout is the real cause of the early and most important atrophy. In reply to a question by DR. COOK, of New Haven, as to why the foot of the diseased limb, for example, should atrophy, Dr. Young said that this was the true atrophy from disease and had not the significance of the early atrophy that results from tetanoid spasm.

"The Diagnostic and Prognostic Value of High Temperatures in Chronic Joint-disease," by DR. ROBERT W. LOVETT, of Boston, was the next paper.

High temperature is a constant accompaniment of acute hip-disease and Pott's disease, the rise occurring independently of the presence of pus. Cases with unopened abscesses, as a rule, do not present higher temperatures than those in which no abscesses are to be detected.

In a series of several hundred observations of afternoon temperature in children with hip-disease and Pott's disease, it was noticed that the rise was from 1 to 4°; that in a general way the rise is greater in the severer cases; and that it may be accorded a certain prognostic significance. Cases in the later stages of the disease and convalescent cases are more likely to present normal temperatures, and any rise is to be looked upon as significant of danger.

As a universal and early symptom—being present in many instances before other physical signs—elevation of temperature is of the greatest significance and importance.

DR. WILLIAM E. WIRT, of Cleveland, presented an "Apparatus for Making Traction," unique in its design and effective in its application. It is of the rachet-and-lever pattern, in principle somewhat similar to the levers of Lagarousse, with the difference that the force of the lever is transformed into rectilinear motion, while in the levers of Lagarousse and in fact in all forms of rachet-and-lever, the force is transformed into circular motion. The advantages of this brace (the design of Dr. Karl H. von Klein, of Cleveland) is that no key, screwdriver, wrench, buckle, or straps are required; it is easy to adjust and to regulate; it is not bulky or bunglesome, and it has a fine grade of adjustment.

SECOND DAY—SEPTEMBER 23D.

DR. AP MORGAN VANCE read an interesting paper, entitled "The Aspirator in Orthopedic Practice," in which he detailed the results of his experience, during the past ten years, with the use of the aspirator in the treatment of abscess from Pott's disease. He employed aspiration in all cases as soon as the diagnosis of abscess was made.

DR. ROSWELL PARK, of Buffalo, presented "A Study of Atrophies." He considered his subject from an historical point of view, alluding to the researches of Bonnet and the discussions and papers of Verneuil. He dwelt at length upon the teachings of Ollier and his pupils. The object of the paper was to popularize teachings on the subject that have been overlooked by the profession.

In a paper on "Diagnosis of Pott's Disease," DR. ROBERT W. LOVETT, of Boston, presented an able *résumé* of the subject, and dwelt particularly upon the importance of physical signs. The diagnosis does not depend upon the history of the case, nor can it be established by the subjective symptoms. The most important physical signs are those caused by muscular spasm and by bone-deformity. The symptoms that are caused by muscular spasm are by far the most important, since they occur before the angular deformity. Lateral deviation of the spine is to be considered a very suggestive symptom, and almost a universal symptom, of Pott's disease. High temperature was considered important as pointing to the probable presence of tuberculous bone-disease.

DR. JOHN RIDLON read a paper upon "Syphilitic Spondylitis in Children," which is to be published in THE MEDICAL NEWS.

DR. T. HALSTED MYERS, of New York, read a paper on "Pott's Disease and Pregnancy."

He considered the subject from two points of view: the effects of Pott's disease on pregnancy, and the effects of pregnancy on Pott's disease. He pointed out that by disease in the lower dorsal, lumbar, or sacral regions, the abdominal cavity is diminished in its vertical diameter, and sometimes also transversely. Abscess usually complicates disease of the lower vertebræ, and may still further diminish the capacity of either the abdominal or the pelvic cavity. In the pelvis the degree of deformity is greater the more the disease has interfered with the normal growth of the parts, and the nearer the pelvis its location. The uterus may be excited to contraction by the most varied peripheral and central influences; destruction of all its motor ganglia is well-nigh impossible, however marked the lesion.

A number of cases reported as occurring in tabetic and paraplegic women prove that the assistance of the abdominal muscles (impaired in these cases by the shape of the abdomen) is not absolutely necessary to the accomplishment of parturition, in the absence of ob-

struction from deformities of the pelvis or from resistant soft parts at the outlet.

The indication *par excellence* in the treatment of Pott's disease is to remove the weight of the trunk from the bodies of the diseased vertebræ. The mechanical effect of a weight placed anteriorly is a most disastrous crushing of the vertebral bodies already softened by disease, and totally unable to sustain even the ordinary weight of the body. The probability of abscess-formation by the weight of the gravid uterus alone is necessarily increased. The danger of rupture of an already existing abscess, or of precipitating pressure-paralysis is aggravated. Aside from this, there is during gestation a hyperemic condition of the cord and its membranes, and of the pelvis generally, and the effect of this on disease of the vertebræ must be pernicious. New centers of ossification appear in the vertebræ at sixteen years, and again at twenty-one years, indicating an unusual activity of the nutritive processes, a condition favorable to the onset of Pott's disease, or for the rekindling of old inflammatory foci. At this age marriage most often occurs. In these cases, however, menstruation is generally delayed a number of years.

Statistics demonstrated that the mortality from Pott's disease and associated conditions is considerably higher in married than in unmarried women.

The chief danger to the mother in cases of cured Pott's disease lies in the malformations of the pelvis and abdominal walls, with the consequent greater strain on a vitality in many cases already enfeebled by the small size of the heart and lungs.

The prognosis is unfavorable in cases that develop during pregnancy. Parturition is occasionally attended with no unpleasant sequelæ.

In deciding upon treatment, four points are to be considered: Is the disease cured, or progressive? Is the pelvis contracted, or practically normal? If on examination the patient is found to be pregnant, and the disease cured, the degree of pelvic deformity will be the guide as to treatment. There can be no fixed rule in these cases; each must be judged by itself. It has been demonstrated that normal birth often follows in cases in which measurements would indicate that it was impossible.

It is important in cases of spinal caries in pregnant women for the orthopedic surgeon to make the diagnosis early, so that they may be put into the hands of the obstetrician at as early a period of gestation as possible, in order that abortion or premature labor may be induced, if necessary.

In cured cases, neither pregnancy nor labor occasions a relighting of the original process. In cases in which pregnancy complicates active disease of the spine, the pregnancy should be terminated at the earliest date possible.

DR. ALBERT HOFFA, of Würzburg, Germany, read one of the most important papers of the session upon "Pressure-myelitis in Pott's Disease," which was illustrated with microscopic slides and diagrams. His investigations showed the most frequent cause of paraplegia in Pott's disease to be a pachymeningitis, the exudate in the sheath acting as a direct poison upon the nerve-centers in addition to the pressure produced by the accumulated fluid.

DR. YOUNG referred to two cases which recovered under his care in which the loss of sensation was present, and insisted upon the distinction between the two varieties of paraplegia that occurs in Pott's disease.

DR. HERBERT L. BURRELL, of Boston, contributed a valuable paper upon "Abscesses in Pott's Disease," in which he described the symptoms, course, pathology, prognosis, and treatment of these serious complications.

His conclusions, from his personal experience, were:

1st. That efficient mechanical support of the spine is the prime factor in the treatment of caries of the spine associated with abscess.

2. That under an expectant plan of treatment abscesses will disappear.

3. That the indication for operative interference is a steady or rapid decline in the patient's general condition.

4. That the operation should consist of thorough evacuation of the abscess, and the establishment of drainage from as near the seat of the disease as practicable.

DR. W. R. TOWNSEND, of New York City, in his paper upon "Abscesses in Pott's Disease," which will appear in a subsequent number of THE MEDICAL NEWS, referred particularly to the increase in our knowledge of tuberculous abscesses that the study of bacteriology has brought about.

DR. JAMES K. YOUNG, of Philadelphia, reported a successful case of bilateral lumbar abscess associated with Pott's disease, in a very young child, and referred to the importance of the fascias in determining the course and exit of abscess in spine disease. The paper will appear in full in a subsequent number of THE MEDICAL NEWS.

The paper by MR. GEORGE A. WRIGHT, of Manchester, England, on "Evacuation of Spinal Abscesses without Drainage," dwelt upon the method of Mr. Mayo Robinson, of aspiration and injection, but more particularly upon that of Mr. Barker, in which a free incision is made, the interior of the abscess scraped with Volkmann's spoon, and then washed out with an antiseptic solution; the excess of fluid is expressed, the wound closed and dressed with firm pressure, to keep the walls in contact and the cavity, as far as possible, obliterated. His conclusions are so excellent that they are given in full. They are:

1. The first essential is *rest*, in its surgical sense, to the spine.

2. When efficient rest has been provided, an abscess should be left to itself for a period of not less than a month, unless it is increasing.

3. If the abscess increases, and is evidently going to open spontaneously, or if there is acute suppuration going on, the abscess should be dealt with by Barker's method, provided thorough asepsis can be practically assured.

4. An abscess that remains stationary for more than two months, or thereabouts, should be dealt with by Barker's method, provided rest has been afforded to the spine throughout the period.

5. Receding abscesses should be left alone.

6. Residual abscesses, if stationary or advancing, should be dealt with by Barker's method, and will certainly be cured.

7. Refilling of an abscess, or persistence of a sinus

after evacuation, should be dealt with by a repetition of the operation as soon as it is evident that repair will not take place; *i. e.*, usually in a month.

8. If there is a doubt about the real maintenance of the asepsis, either from want of training on the part of the surgeon or his assistants, nurses, friends, etc., the abscess should be left alone, or dealt with by aspiration and injection of iodoform.

DR. SHAFFER believed that as long as abscesses were small, they should be allowed to open spontaneously. In large abscesses, when there is a question of life or death, his practice is not to open the abscesses but to depend upon hygiene, mechanical and climatic treatment, under which many of his cases had recovered.

DR H. AUGUSTUS WILSON, of Philadelphia, said that he believed that the good effects obtained by operation were largely due to the immediate closure of the skin-wound. He was not impressed with the advantages of the aspirator, except for diagnosis. He believed that when it was advisable to open Pott's abscess it should be done by free incision, either at the most dependent part or through and through, and closure of skin-wounds by subcutaneous suture and collodion before applying dressings.

DR. WILSON had found decided benefit from hyper-distention with peroxide of hydrogen (to be employed only when free incision had been resorted to), and subsequent douching with hot water.

DR. HOWARD MARSH, of London, said the opinion was growing strongly and constantly in England that these abscesses ought to be opened. In regard to the opening and thorough cleansing of the abscesses there is a difference of opinion. Mr. Barker favors the opening and dressing. Mr. Marsh believes in opening freely, cleansing thoroughly, bringing the edges together, and depending on rest and constitutional treatment.

He was at one time an advocate of aspiration, and later of hyper-distention, but in a large number of cases septic action set in, and he had abandoned the procedure. His method is free incision at once when diagnosis of abscess is established; in not more than 4 or 5 per cent. does asepsis fail, and in the large majority of cases recovery occurs. He believes that one reason for opening these abscesses is to stop the evil result of pressure symptoms.

DR. BRADFORD agreed with Mr. Marsh, and expressed the opinion that the opening of large abscesses and washing with hot water is not attended by any shock, and referred to twenty-five cases of very large abscesses in which opening was not attended by shock.

Large abscesses are sometimes absorbed; but the opening of large abscesses was unattended with shock, and time is saved.

DR. HENRY LING TAYLOR, of New York, read a paper on "The Value of Mechanical Treatment in Old and Neglected Cases of Pott's Disease."

The object of mechanical treatment in Pott's disease is twofold: first, to provide rest and protection for the spinal column and proper hygiene for the patient until the inflammatory process is arrested and repair is complete; secondly, so far as possible, to prevent or mitigate deformity. Fortunately, the same means, antero-posterior leverage support, may be adapted to both ends.

The course of this disease is often tedious, and definitive healing extremely slow. Complete bony ankylosis of the diseased vertebræ is both later and rarer than usually supposed, as indicated by more or less mobility through the kyphosis, often discoverable by careful testing in long-standing and greatly-deformed cases. Owing to imperfect treatment or other causes, rational symptoms and disability often persist for many years, coincidently with a gradual increase of deformity; or after a considerable period of immunity, the original trouble may be lighted up by a strain or fall.

These old and often apparently desperate cases usually respond kindly to efficient mechanical treatment, which should be employed to the same definite end, and with the same painstaking as in more recent ones. Even when deformity is excessive, moderate improvement of the figure may exceptionally be looked for, and increase can usually be prevented; the subsidence of local inflammation is evidenced by improvement in the patient's health, and the disappearance of suffering and general and local symptoms. Abscesses and paralysis do not prevent a favorable prognosis.

The mechanical treatment of Pott's disease in those adults and cases of long standing that will heartily cooperate with the surgeon is not only hopeful, but usually successful, in removing disease and the disability dependent upon it, and no patient should be denied the opportunity for relief on account of age, severity of symptoms, or the long duration of his disease.

(To be continued.)

AMERICAN PEDIATRIC SOCIETY.

Third Annual Meeting, held at Washington, September 22, 23, 24, and 25, 1891.

FIRST DAY—SEPTEMBER 22D.

WHEN the meeting was called to order, the Secretary read a communication from DR. WILLIAM PEPPER, Chairman of the Executive Committee of the Congress, admitting the Pediatric Society to membership.

The President, DR. T. M. ROTCH, of Boston, made an eloquent appeal for more scientific work in pedriatics, and expressed the hope that the work of the members of the Society would compare favorably with that of those in other branches of the profession. He felt that this had not been the case sufficiently in the past.

DR. J. LEWIS SMITH, of New York, read a valuable paper on "How to Prevent Complications and Sequelæ in Scarlet Fever."

He first pointed out that the type of scarlet fever varied in different epidemics, the disease sometimes being mild, with a low mortality; at other times severe, with a high mortality.

No other disease of childhood presents as many complications; and sometimes death occurs from the intensity or malignancy of the disease.

The intense inflammation of the fauces, which is sometimes followed by gangrene, inflammation of the Eustachian tube, otitis media, adenitis and cellulitis, together furnish abundant evidence of serious local trouble, as well as of systemic intoxication.

In scarlatina, various bacteria abound on the faucial surfaces; of these, streptococci have been constantly

found, and seem to predominate. It would appear that these enter the circulation, and may give rise to certain of the complications.

Some authors ascribe the rheumatism that occurs in the course of scarlatina to bacterial agencies; many pathologists are also of the opinion that the glomerulo-nephritis is caused by microörganisms.

In view of these facts, the application of antiseptic solutions to the naso-pharynx would seem to be useful in preventing the entrance of the germs into the body, with the serious results that may follow.

Peroxide of hydrogen in the strength of one part to four of water may be used for the fauces, and one part to eight of water for the nares; or corrosive sublimate may be used in the strength of two grains to a pint of water, but not to be applied oftener than every three hours.

Dr. Smith uses a lotion composed of boric acid, two drams; borate of soda, two drams; chloride of soda, one dram; and water, a pint. One fluidram of this mixture is to be injected into each nostril every hour. In using any one of these lotions, they should first be warmed.

In addition, in the sthenic cases, with high fever, cold applications to the throat may be useful.

Eclampsia is always a serious complication. It occurs early from hyperpyrexia, or if late in the disease, from uremia. Restlessness, jactitation, and delirium should arouse suspicions of possible eclampsia, and indicate measures to prevent this complication. If, in the early stage, cold-water treatment to reduce fever, in addition to the local antiseptic alluded to, with the internal administration of bromides, may forestall this alarming complication.

Aconite and phenacetin may confidently be recommended in the hyperpyrexia of cases not markedly adynamic. In general, the other antipyretics are either not to be relied upon, or are harmful. Sodium salicylate at times causes albuminuria, or may be the starting-point of a nephritis.

Ante-mortem heart-clots would probably be prevented by active stimulation—the administration of musk, ammonia, etc. Scarlatinal rheumatism, in itself not a serious complication, becomes important when it is considered how frequently endocarditis or pericarditis is simultaneously present.

Though it has been suggested that both rheumatism and glomerulo-nephritis occurring in scarlatina are of bacterial origin, either may be caused by cold; it is, therefore, necessary to avoid exposure of the patient, especially during desquamation.

DR. FRUITNIGHT, of New York, expressed the belief that the complications last mentioned result from exposure; he therefore always insists upon (1) warmth, (2) rest, and (3) milk diet.

A paper on "The Most Diagnostic Symptoms of the Early Stage of Lobar Pneumonia, and the Differential Diagnosis from Such Diseases as Meningitis, Malaria, Scarlet Fever, etc.," was read by title, the author, DR. T. S. LATIMER, of Baltimore, being unable to be present.

DR. F. FORCHHEIMER, of Cincinnati, read a paper on "The Diagnosis of Consolidation of the Lung from Effusion (serous or purulent), and the Differential Diagnosis between Lobar Pneumonia and Broncho-pneumonia." He first considered the diagnosis of consolidation from effusion. In classical cases little difficulty should be experienced, but the matter is not so simple in atypical cases. The possibility of encysted effusions must be kept in mind. Dr. Forchheimer does not concur in the view that this is a common condition in children. Most encysted pleurisies in childhood are tuberculous. Inspection may reveal important information. In the case of fluid, there will possibly be bulging. Especial stress was laid upon the increased resistance, the sensation on percussion being characteristic. In consolidation there may be contraction, or at least no bulging, with increased vocal resonance, and fremitus and blowing breathing, perhaps with râles. In children auscultation may be misleading, and is, therefore, not so useful as in the adult. Egophony is rarely heard in children. Dr. Forchheimer cannot admit the existence of idiopathic pleurisies. Empyema was considered a secondary effusion; the use of the terms primary and secondary in this connection he thinks still desirable. The effusion is sometimes gelatinous, so that hypodermatic puncture does not disclose its presence.

In tapping, the puncture should be made as low as possible, in the ninth or tenth interspace—in recumbency, in the posterior axillary line; in the upright posture, in the mid-axillary line; and if the body is inclined forward, in the anterior axillary line.

DR. WILLIAM OSLER, of Baltimore, followed with a paper on "The Diagnosis of Broncho-pneumonia (Acute and Chronic) from Tuberculosis," in which he pointed out that broncho-pneumonia is a lesion, and not a disease. The following suggestive points were considered: 1. The frequency of tuberculosis in infants; tuberculosis is much more frequent than was formerly supposed. 2. The circumstances under which cases of broncho-pneumonia may occur; a child may appear perfectly healthy, with an excellent family history, yet suddenly be attacked; in pulmonary tuberculosis in children, the bronchial glands are involved; convalescence from the acute fevers, measles, scarlet fever, whooping-cough, etc., are fraught with danger. 3. Clinical types; the acute pneumonic form of tuberculosis is not recognized in infants; the condition is usually either lobular or pseudo-lobar. 4. Diagnosis; in acute cases, it is impossible to determine whether the condition is tuberculous or not. Tuberculous and non-tuberculous disease probably affect the upper lobes of the lung with about equal frequency. In the middle portions of the lung, tuberculous disease is apt to predominate in frequency. Bilateral disease is more common after diphtheria and measles.

The physical examination may yield uncertain signs; the family and personal histories are therefore important. If possible, the sputum should be examined.

DR. L. EMMETT HOLT, of New York, followed with a paper on "The Diagnosis of Broncho-pneumonia from Bronchitis, also the Temperature-range in Acute Pneumonia, both Lobular and Lobar." Dr. Holt's experience has been very rich, and being connected, as he is, with the New York Foundling Asylum, opportunity is afforded of watching the cases from their incipiency, as well as before and after the illness. Many temperature-charts were exhibited, showing different types of the disease. Dr. Holt does not believe that the remittent variety has any connection with malaria. In acute bronchitis the temperature is apt to rise abruptly to 104°

or 105°, the fever is continued, and a crisis occurs on about the fifth or seventh day, the temperature frequently falling below the normal. In one-half of the cases a temperature of 105° or more was reached. The highest temperature that he had observed followed by recovery was 106¾°. The mortality increases rapidly as the temperature rises above 104.5°. About one-half of the cases terminated by lysis. The critical day seems to be the seventh. In broncho-pneumonia, the temperature is apt to rise gradually, in a few days to become fluctuating, and finally to fall gradually. The most favorable temperature seems to be from 104° to 104.5°. The mortality increases with much variation either above or below this point.

The differentiation of acute bronchitis from broncho-pneumonia would be made by the temperature-record, the severer symptoms of the latter, and the physical signs. If there is continued high temperature for some days, pneumonia should be suspected, but a low temperature does not exclude pneumonia. Cyanosis and evidences of consolidation point to pneumonia. Again, unilateral bronchitis rarely or never occurs, whereas a localized bronchitis of the finer tubes would indicate pneumonia.

In the discussion that followed, DR. JACOBI, in speaking of the delay in resolution, expressed the belief that the pneumonia was generally a mixed one; that rarely did pure lobar or lobular pneumonia occur in infancy. He thinks that the diagnosis may frequently be made on the second day—difficulty arising in cases in which the pneumonia is central. Some cases are apt to be mistaken for meningitis. The respiration may here be the deciding point. In his experience many cases have occurred in which dulness was detected only in the axillary region, and thus apt to be overlooked. Only the gentlest percussion should be applied in the case of children. Bronchophony, if detected, is a valuable sign.

Enlarged mediastinal glands may occasion delay and difficulty in arriving at a diagnosis.

DR. HOLT had frequently observed at autopsies the existence of a diffuse purulent meningitis in cases in which there had been no brain symptoms before death.

SECOND DAY—SEPTEMBER 23D.

DR. W. OSLER, of Baltimore, presented "A Specimen of Congenital Heart Disease."

DR. A. SEIBERT, of New York, presented "Further Report on Sub-membranous Local Treatment of Pharyngeal Diphtheria." Injections of fresh aqua chlori (U. S. Pharmacopœia) are made into and beneath the false membranes found on the tonsils and other accessible parts of the pharynx, about fifteen drops being injected into each spot; if necessary, from six to eight injections can be made without causing toxic effects. The syringe for the purpose consists of a metal rod and a small plate holding the points of five hypodermatic needles, all attached to an ordinary hypodermatic syringe. Thirty-five cases treated by this method had already been reported. To these were added thirty-seven treated by others, and thirteen treated personally. Of these fifty cases four were of the scarlatinal variety. The age of the patients ranged from five months to thirty years, thirty-three being under seven years of age. In forty-two cases the injections of chlorine water proved effectual in checking the diphtheritic process; partial effects were observed in four cases, and no effect in three cases.

Imperfect results were obtained in cases in which inaccessible portions of the pharynx were primarily involved. Of the fifty cases, four ended fatally. In all, eighty-five cases treated by sub-membranous injections have been collected. Diphtheritic paralysis was not noticed in any of these cases. Six died, or about 7.5 per cent.

The conclusion arrived at was, that in pharyngeal diphtheria submembranous local injections of fresh chlorine water may, with good effect, be made in all cases in which local treatment is applicable.

DR. H. KOPLIK, of New York, regarded the paper as a perfect bacteriological report as applied to therapeutics, but he expressed the admonition that diphtheria varies greatly in different epidemics. To a question from Dr. W. P. Northrup he replied that he could not say how deep the bacteria could be found, but he believed that the treatment proposed by Dr. Seibert was in the proper direction, as the future would show.

DR. J. L. SMITH, of New York, said that the Klebs-Löffler bacillus does not enter the tissues, but its toxic products occasion the systemic infection. He feared that injury to the bloodvessels might allow the ingress of the poison.

DR. L. E. HOLT, of New York, stated that he had not been successful in the treatment of diphtheria by medicinal means. He expressed the opinion that diphtheria is first a local, then a constitutional disease. Viewed in that light, he believed the treatment by injections of chlorine water to be proper.

THE PRESIDENT stated that he was never sanguine in the treatment of diphtheria. In his experience the results of treatment were the most satisfactory when the false membrane had been confined to the tonsils.

In closing the discussion, Dr. Seibert stated that he had found the Klebs-Löffler bacillus in a large proportion of his cases, which he regarded as conclusive that he had treated diphtheria, and not some similar but different affection. He had only noticed extension of the membrane when he had not made the injections with thoroughness. The injections should reach the submucous tissue, and general treatment should not be omitted. He had rarely found it necessary to use a gag, and if the first injection was thorough he was not compelled to repeat it.

DR. W. D. BOOKER, of Baltimore, read an interesting report of a "Case of Ulcerative Catarrhal Dysentery," giving details of his bacteriological investigations.

DR. C. W. EARLE, of Chicago, presented a paper entitled "Manifestations of 'La Grippe' in Children," which the Society moved be abstracted and read at a future meeting.

The paper of DR. DILLON BROWN, of New York, on "The Treatment of Laryngeal Diphtheria by Calomel Sublimations," was read by title; as was the paper of

DR. F. E. WAXHAN, of Chicago, on "Stricture of the Esophagus Occurring in Children," with report of a case; and that of

DR. F. HUBER, of New York, on a "Case of Pulmonary Abscess; Operation and Recovery, with Remarks."

(To be continued.)

THE MEDICAL NEWS.

VOL. LIX. SATURDAY, OCTOBER 3, 1891. NO. 14.

ORIGINAL ARTICLES.

THE TREATMENT OF FRACTURES OF THE HUMERUS INVOLVING THE ELBOW-JOINT.[1]

BY LEWIS A. STIMSON, M.D.,

PROFESSOR OF SURGERY, UNIVERSITY OF THE CITY OF NEW YORK; SURGEON TO THE NEW YORK HOSPITAL, ETC.

THE special interest that belongs to the subject that has been allotted to me for presentation on this occasion arises from the frequency with which fractures of the lower end of the humerus are followed by more or less diminution of the functions of the elbow-joint, and by deformity of the region or of the limb. It therefore seems proper, and in keeping with the limited time at our disposal, that the discussion should turn mainly upon the causes of these unfavorable results and the means by which they can be best and most surely avoided. It is also assumed that in the selection of this subject for discussion before this Association, the members of which are so experienced and so thoroughly familiar with all its features, the intention was not to invite the expression of novel views, or the presentation of original observations, but to afford an opportunity for an expression of the collective opinion of the Association concerning the best methods of treatment and the prognosis, and thus to supply a guide and protection for less favored members of the profession.

1. CAUSES OF LIMITATION OF MOTION.—Permanent stiffness of the elbow after simple fracture is commonly due to a change in the shape of the articular surfaces, or in their relations to one another, that destroys the coincidence of the axis of curvature with that of motion, and thus limits the range of motion; or, to an overgrowth of bone upon the surface of the humerus that arrests the movement of the olecranon or coronoid process into its corresponding fossa; or, to a more or less extensive ossification of the ligaments and capsule.

As in flexion and extension the normal range of motion at the elbow is great, and since over a large surface the bones composing the joint are in close contact with each other, it follows that a comparatively slight change in shape or deviation of an axis may have a marked effect, and one that will be only partly relieved by the gradual yielding of the ligaments, or by the absorption of opposing bone under persistent stretching and pressure. It is like the defective "centering" of the hinges of a door.

Overgrowth of bone excited by the traumatism is much more frequent in the young than in adults, but so, too, are fractures of the lower end of the humerus, and in this overgrowth we find a cause of limitation of motion that, even if sometimes over-estimated because unreduced displacements are mistaken for it, is yet sufficiently frequent to merit serious consideration. This overgrowth is in part exuberant callus, and in part new bone formed beneath the periosteum adjoining the line of fracture. Exuberant callus is usually formed when the displacement has been great and has not been well reduced, and the obstacles to motion created by it are, therefore, associated with others arising from change in the relations of the joint-surfaces; but it may occur even when the displacement is slight, as in one of my specimens, and in one possessed by the Charité at Berlin (Gurlt, II., p. 107). Overgrowth under the periosteum, extending to a greater or less distance from the fracture, is due to the irritation of the traumatism, and doubtless in part to the implication of the periosteum in the injury to the extent of its stripping-up in the displacement.

The frequency with which limitation of motion follows fracture, and with which it is due to each of these different causes, cannot well be established by statistics. Most of the cases are treated in dispensaries, and the ultimate result seldom forms part of the record. In the out-patient department of my service at the Chambers Street Hospital, which is probably the largest surgical dispensary in New York, receiving about 20,000 cases annually, there are treated each year some twenty cases of fracture of the lower end of the humerus, exclusive of the epicondyles. With a view of determining the relative frequency of the different forms of fracture and the character of the results, I have collated the statistics for the last six years. In a number of the cases some uncertainty arises through doubt as to the correctness of the diagnosis, but in general they show that fractures of the internal and external condyles taken together constituted nearly three-fourths of all, supra-condylar and inter-condyloid, or T-fractures, the remaining fourth. Fractures of the internal and external condyles, when compared with each other, were of about equal frequency, although they differed so greatly in different years, and under different assist-

[1] Read at the meeting of the American Surgical Association in Washington, D. C., September 25, 1891.

ants, that errors in diagnosis seem probable. The supra-condylar and inter-condyloid were of nearly equal frequency, the former being rather the more frequent. The record of ultimate results is too incomplete to be of much service, as it ceases in most cases with a statement of the condition at the time of or shortly after the removal of the splints. In the inter-condyloid fractures flexion was then possible to, or slightly within, a right angle; of the others, in fully one-half no mention of the range of motion is made, while in those in which such mention is made it is usually described as "excellent," "perfect," or "good," and only rarely as "poor."

The specimens preserved in museums are few in number and serve only to establish the nature of some of the various causes. A search through the principal hospital collections of New York has yielded me only two. In one, a supra-condylar fracture, extension is prevented by a broad, flat osteophyte occupying the olecranon fossa; in the other—also supra-condylar, but with displacement—there is a broad mass of new bone behind, which is solidly united to the humerus and also to the tip of the olecranon process. A third specimen, one of fracture of the ulna at the base of the olecranon, shows another form of ankylosis—one by bony union between the opposing bony surfaces; I believe this form is rare, except after suppuration of the joint.

Upon these facts I make at present but one reflection, namely, that as limitation of motion may be caused by a bony outgrowth from the humerus, itself the result of a persistent displacement of a fragment or of the separation of the periosteum, the most efficient way to prevent it lies in an exact diagnosis and reduction of the displacement, and in the avoidance of any subsequent irritation of the periosteum.

A third cause of limitation of motion is found in thickening of the capsule and peri-articular tissues by the products of inflammation. The cause may act temporarily, during and for a limited time subsequent to the period of repair, or permanently by the production of new fibrous and cicatricial tissue, which forms abnormal bands connecting the different members of the joint and limits the extensibility of the peri-articular tissues and their mobility upon one another. As a temporary condition, its anatomical changes are presumably limited to an exudation that infiltrates the soft parts and wholly disappears with more or less promptness after the repair of the main injury and the consequent cessation of the irritation. Except in very rare cases under the influence of a constitutional dyscrasia, a permanent limitation of motion does not follow this form of reaction. In the more permanent form, the anatomical lesions are much more varied and extensive: the soft parts are torn and displaced, the fixed cells proliferate, and the new tissue formed thereby constitutes a true cicatrix that strongly binds together parts whose independence of one another is essential to mobility of the joint. In place of the loose capsule in front or behind that is thrown into folds by movement in one direction and straightened out to its full extent by movement in the opposite direction, we find a short, firm band—an abnormal anterior or posterior ligament—that limits the separation of the points to which it is attached to a distance that is equal to its length. If the osteogenetic tendency is marked, or if the irritation is kept up, this new tissue or this thickened tissue may become ossified in whole or in part. The natural history of such fibrous tissue is known: after its full evolution has taken place, it may diminish in thickness and may be rendered longer and more pliable by the constant repetition of slight pressure. We see abdominal cicatrices yield and stretch under intra-abdominal pressure; we see joints stiffened by injury or disease slowly regain freedom of motion under the natural, unforced use of the limb; and although most of this stretching or mobility is probably due to the yielding of the connections of the cicatrix with the surrounding cellular tissue, yet some of it is the result of the thinning and stretching of the scar itself.

The existence of this cause of limitation, the effects of which are constantly observed after an injury or an inflammation of a joint that has compelled its prolonged immobilization, led to a widespread belief that it arose from, or was materially favored by, the immobilization; and although of late years the opinion has been vigorously, and, in my opinion, successfully, combated by surgeons of large experience and accurate methods of thought, notably by Verneuil and Sands, it still finds expression in the quite general use of passive motion at an early stage, with the object of thereby removing or preventing the cause and its consequences.

The belief appears to have arisen partly by generalization from certain observed anatomical conditions, partly from the unquestionable fact that if a joint is kept movable it will not be stiff, and partly from the clinical observation that many joints that have been treated by passive motion have preserved or regained their functions. The opposing view is based upon the theory, supported by observation and experiment, that immobilization is not in itself a cause of ankylosis—that it is, on the contrary, the most efficient agent we possess against the inflammation which is the primary cause of most stiffness, and that passive motion is powerless to prevent ankylosis when conditions contributory thereto are present. According to this view, passive motion is either harmful or needless.

Let us briefly consider these opinions and arguments, premising that, since in any given case it is practically impossible to say that a joint that has regained its mobility under passive motion would not have done so equally well under immobilization, and that one that has stiffened under immobilization would not have equally stiffened under passive motion, our attention must be mainly given to anatomical and theoretical considerations.

The anatomical facts advanced in favor of the early use of passive motion are the outgrowths of bone that we have seen form and overlap the articular surfaces and mechanically oppose motion, and peri-articular and intra-articular bands that bind the members of a joint together and limit motion by their shortness and inextensibility. With reference to the outgrowths of bone, it is argued that if the member, the movement of which in a certain direction has been prevented by the formation of such a spur, had been previously pressed into the place thus occupied, the spur could not have formed there; or, that if it had been repeatedly pressed against the spur during its period of formation, the latter would gradually have yielded, and, under the influence of the pressure, would have become absorbed. In like manner, with reference to peri-articular and intra-articular bands, it is claimed that systematic passive motion will prevent their formation, or, if formed, will break or stretch them while they are still weak and extensible. If such a statement contained all the elements of the case, the argument and the practice would have to be accepted as sound. But it does not contain all. In respect of the formation of the spur of bone, such a spur, of course, cannot form in a place already occupied by another bone, but the loosened periosteum, by which it is so often produced, is simply pushed to a higher place by the manipulation, and there produces it. Take, for example, such a spur in the olecranon fossa: if by timely extension of the forearm the olecranon is placed in the fossa, the spur does not form there, and extension is preserved; but the spur does form immediately above the fossa, and by carrying the attachment of the posterior capsule to a higher point, and by permitting the union of the lacerated surrounding tissues with the maximum shortening, it as effectually opposes flexion as the nodule whose formation it prevents would have opposed extension. The result in respect of immobility is the same; the difference is only in the attitude in which the joint is henceforth fixed.

With reference to the absorption under repeated pressure of a nodule of bone that is forming or has already formed, the arguments in support of it are wholly theoretical. It is conceivable that while the nodule is still soft, before ossification has become complete, its shape can be modified by pressure, but it is also apparent that such modification can be more surely affected at that time by permanent pressure, by retaining the limb for a day or two in the position in which the pressure is made, than by frequently-repeated pressure; this is both because the modification is maintained and because the irritation that favors the production of bone is less. Clinical experience indicates that such absorption is a very slow process, and that it is favored quite as much by the general tendency to the disappearance of superfluous bone as by pressure.

But it is against the other cause of stiffening, peri-articular thickening and bands, that the advocates of early passive motion claim it is most useful. No delay is permissible; a week, ten days, or a fortnight at the latest, after the injury it must be begun. The limb is taken from its splints, and while the swollen and sensitive elbow is grasped with one hand to afford the necessary support and to keep the fragments from being displaced, the forearm is slowly and "gently" moved back and forth in flexion and in extension. As the object is to stretch or break bands that are forming, the movement must necessarily be carried beyond the points where resistance begins. What is the result? We have all seen it. The patient bears the manipulation with such fortitude as he may possess, but his muscles contract involuntarily and make the range of motion less and less, and, after a few minutes, perhaps only a few seconds, of the torture, the surgeon is quite ready to accede to his prayer that it shall cease, and the limb is replaced in its splint. When the surgeon returns the next day he learns that the pain continued for several hours, and he finds the limb more swollen, the range of easy motion even less. He persists, and is finally arrested either by the refusal of the patient to permit the manipulation, or by the onset of acute inflammatory symptoms, or by recognition of the fact that notwithstanding all his efforts the range of motion is steadily diminishing. He waits a few days, perhaps, and then moves the joint freely under ether—"breaks it up," as we say; but again it stiffens, and again he sees his efforts fail, and at last, weary of the struggle, he abandons it. Thereafter, one of two results follows: either the joint remains permanently stiff, or, after the swelling and soreness have disappeared, it gradually regains its mobility under the natural use of the limb.

The same two results, permanent stiffness and more or less complete restoration of function, are also found after prolonged immobilization. The problem may, therefore, be stated as follows: After an injury a joint becomes tender, swollen, and stiff. In certain cases, under either method of treatment, the stiffness is permanent; in others it gradually disappears. Is passive motion or immobilization

during the first six weeks or two months likely to furnish the larger proportion of the latter class?[1]

The primary cause of the exudation and of the proliferation of connective tissue that are recognized as the anatomical obstacles to motion is, of course, the original traumatism; the secondary cause is the following inflammatory reaction. The severity of the injury is in each case a fixed quantity; the variable factor, the only one that is to be increased or diminished by the treatment, is the inflammatory reaction, and to this, therefore, our attention may be restricted. The question, then, may be stated in this form: How do passive motion and immobilization respectively affect the inflammatory reaction following an injury to a joint? To state the question is to answer it. Rest is universally admitted to be the best antiphlogistic measure that can be applied to an inflamed joint. Under its influence we see the swelling, heat, and tenderness subside, and we know that the amount of cicatricial tissue that has formed is only that which has come directly from the extent of the primary traumatism. The condition may be illustrated by comparison with similar conditions intentionally created by the surgeon, such as supra-condylar osteotomy or osteotomy of the internal condyle of the femur for the correction of a genu valgum. In these two operations the lesions of the bone and soft parts are the same in kind as in supra-condylar fracture and in fracture of the internal condyle, though perhaps less in degree; we invariably treat them by immediate and permanent immobilization, and under that treatment we find that the reaction is slight and the maintenance of function complete. Is there any adequate reason to believe that the reaction and the results after a fracture treated as promptly and in the same manner would be less satisfactory.

It only remains to inquire whether rest has compensating disadvantages to offset its advantage in restricting the amount of cicatrical tissue, and whether passive motion is free from them. An important disadvantage at once suggests itself: namely, that the torn tissues may unite with shortening, and the possibility of this must be admitted. But, will passive motion prevent it? Consider what takes place. When the joint is moved the reuniting tissues are again torn apart and a fresh trauma inflicted; the irritation is thus constantly renewed and extended, and the increasing difficulty in movement that we have clinically observed is explained by the inflammatory thickening of the untorn tissues surrounding those which have been torn. New tissue develops in this thickened untorn layer, and as it contracts in its natural evolution it more and more effectually prevents the separation of the torn tissues until ultimately they unite just as they would have united in the first place, and the only effect of the treatment is to have thickened and strengthened the cicatrical band whose formation it was designed to prevent. Both clinical observation and theoretical considerations indicate that passive motion in this stage not only does not avoid the disadvantage arising from immobilization, but on the contrary, actually increases it. In short, it may be said that the ankylophobia of the surgeon is more dangerous to the patient than the traumatism.

Is there, then, no alternative? Must we accept a certain amount of limitation of motion as unavoidable? In the present state of our knowledge, and in certain cases, I think we must. But its extent can be measurably restricted. Systematic massage has proved to be an efficient means of hastening the absorption of the exudation and the restoration of mobility, as has also permanent elevation or suspension of the limb; and the reunion of the torn tissues with shortening may be opposed by change in the attitude of the limb made at intervals of a few days.

To avoid misunderstanding, let me repeat that in what has thus far been said about passive motion its use during the stage of reaction alone has been in mind—its use during the period in which it is followed by persistent pain and soreness. At a later period, as supplementary to the natural use of the limb, it has its value.

2. DEFORMITY.—Of the various deformities that may result from unreduced displacement after fracture, I shall here speak of only one—that which follows the fracture of either condyle, especially the inner, and is rather widely known as the "gun-stock" deformity. It was carefully studied and described by Dr. O. H. Allis in 1880. It will be remembered that the long axis of the fully extended forearm deviates outwardly from that of the arm, and that as the axis of motion at the elbow is at right angles to the forearm it deviates correspondingly from the transverse axis of the condyles, passing through them at a lower level on the inner than on the outer side. A displacement of the internal condyle upward or of the external condyle downward, their attachments to the radius and ulna remaining unbroken, will annul this outward deviation of the forearm and bring the latter into line with the arm or even incline it to the inner side, and, as the breadth of the condyles is not great, a comparatively slight displacement, say ¼ or even ⅛ of an inch, of the condyle may be sufficient to effect this change. This is the "gun-stock deformity;" it is hardly noticeable when the elbow is flexed, but is very obtrusive and ungraceful when the elbow is extended. In

[1] Isolated intra-articular bands that can be broken by a single movement and have little or no tendency to reunite are rare and may here be disregarded.

the case of fracture of the internal condyle the displacement upward of the fragment can be readily occasioned by pressure upward against the flexed elbow, the pressure being transmitted to the condyle through the olecranon; such pressure is produced when a posterior rectangular splint is used with a sling that passes under the elbow and is short enough to take the weight of the entire limb. If the limb, with a similar splint, is supported only at the wrist this undesirable pressure is not made, for the arm carries the splint, not the splint the arm. Spasmodic contraction of the flexors and extensor of the forearm may also make this pressure. In the case of fracture of the external condyle the mechanism of displacement of the fragment downward is not clear; Dr. Allis thought it might be effected by the pressure of the circular turns of the bandage that secured the limb to the splint—pressing the radius, and with it the fragment, toward the posterior border of the ulna; but this seems to me to be very improbable.

The indication for treatment is clear: reduction of the displacement, if it exists, by pressure upon the fragment, or by abduction of the extended forearm until its outward deviation is equal to that of its fellow, and immobilization by dressings that will not reproduce the displacement.

Treatment.—After this examination of the principles of treatment the details need not long occupy us. The importance of immediate and complete reduction of such displacement as may exist when the case comes under observation is such that whenever a reasonable doubt exists as to the extent of the displacement or the completeness of the reduction, an anesthetic should be employed.

In *supra-condylar* fracture, in which the usual displacement is of the lower fragment backward and upward, permanent traction is usually necessary to overcome the displacing action of the flexors and extensor. This can be effected by vertical suspension of the limb, the patient being kept in bed, or by a weight suspended from the upper part of the flexed forearm while the patient is erect. The former is open to the objection that it permits an angular displacement, the lower fragment being inclined backward, and that it requires confinement to the bed; but there is no doubt in my mind of the advantages that accrue from its use in the first fortnight after the injury; this is especially true of compound fractures, for it diminishes the reaction, permits the usual bulky dressing that is so desirable for the protection of the open wound, and at the same time secures a more thorough and persistent reduction than can usually be maintained by splints placed over such a dressing. Suspension is made by strips of adhesive plaster placed along the front and back of the forearm and attached to the support by India-rubber cords, or a weight and pulley. In simple fractures the other method may be employed from the beginning, and in compound fractures after they have become simple under suspension. An efficient procedure is to encase the limb in plaster-of-Paris from the hand to the axilla, with the elbow at a right angle, support the wrist by a sling, and suspend a weight of not more than five pounds from the flexure of the elbow. If swelling is feared, the encasement may be limited to the forearm and made continuous with anterior and posterior plaster splints along the arm.

In *inter-condyloid* fracture with marked separation, there is no practicable means surely to maintain reduction, and considerable limitation of motion is to be expected. The varying contractions of the muscles, the pressure of the enveloping fascia, increased by the swelling, and the impossibility of direct control of the fragments, combine to make the result largely a matter of chance. Experience with compound fractures in which the shiftings of the fragments could be recognized by sight and touch, has impressed me with the exceptional difficulties presented by this variety of fracture; in one case (compound) I felt constrained to pass a long steel pin transversely through both condyles and the long projecting end of the upper fragment, for in no other way could they be kept in apposition. As even in simple cases the reaction is marked, complete encasement in plaster-of-Paris during the first week is dangerous, unless made so loose that its support is inefficient. I prefer a broad, heavy posterior plaster splint, extending from the axilla to the hand and covering about two-thirds of the circumference of the limb, the elbow being flexed at a right angle; while hardening, it can be so moulded by pressure about the elbow that it will do much to maintain the fragments in place. Traction by a weight can be used as in supra-condylar fracture.

In fracture of *either condyle* the habitual method of treatment is by a posterior rectangular splint of metal or plaster, with the substitution in many cases of plaster encasement during the second week. The forearm is supported across the chest by a sling *at the wrist* (within, not outside, the splint), and the dressing should be worn for about a month. Immobilization in full extension of the elbow has been employed in order more surely to prevent the displacement that causes the gun-stock deformity, but the method has certain disadvantages that will probably prevent its general acceptance. There is sometimes a marked tendency to displacement forward and tilting of the fragment (internal condyle), and the swelling of the dependent hand often causes much discomfort. The latter disadvantage does not appear when the patient is kept in bed. It has seemed to me to be advisable in some cases to

employ this method for the first ten days or a fortnight and then to substitute flexion at a right angle, hoping that by that time the fragment will have contracted adhesions that will prevent its easy displacement upward.

With fracture of either condyle is sometimes associated dislocation of the bones of the forearm and the fragment from the humerus; this complication is more frequent with fracture of the internal condyle, the dislocation being backward and upward, and the head of the radius resting behind the external condyle. Under such circumstances retention may present special difficulties; they appear to be best met by immobilization, with the elbow flexed well within a right angle.

If the case is one to which the necessary time can be given, daily massage of the limb may be advantageously employed to hasten convalescence. It should be made very gently at first, and the pressure gradually increased. The sittings may occupy ten or fifteen minutes, and the rubbing should be from below upward. Care must be taken to avoid giving pain, either by too great pressure or by movement of the joint.

For the reasons already given it may in some cases be advisable to change the angle of flexion from time to time; and in any case in which absolute fixation or great limitation of motion is expected, that attitude should be given to the joint in which, if stiff, the usefulness of the limb will be greatest.

After-treatment.—The length of time for which the splint must be worn is greatest—about six weeks—for the supra-condylar and inter-condyloid fractures, and about four weeks for those of either condyle. After removal of the splint the limb should, for a few days, be supported in a sling, and exercised in slight movements. If the increase of the range of motion under natural use should be slow, it may be hastened by passive motion or by special exercises, as by carrying a weight to increase extension and by India-rubber traction from the wrist to the shoulder to increase flexion.

A STUDY RELATIVE TO THE FUNCTIONS OF THE REPRODUCTIVE APPARATUS IN AMERICAN INDIAN WOMEN.[1]

BY ANDREW F. CURRIER, M.D.,
OF NEW YORK CITY.

A CAREFUL examination of the Indian question as it is presented to the people of the United States, will lead to the conclusion that the Indians must submit either to civilization or extermination. Civilization and savagery cannot coexist. In close contact savagery always has to yield. To break up tribal distinctions, give the Indians land in severalty, educate them, abolish polygamy, barbarous costumes, and heathenish practices, and to keep whiskey away from them, is the present policy of the Indian Bureau, and it is wise, just and hopeful.

The author's investigations were made with the approval and coöperation of Hon. Thomas J. Morgan, Indian Commissioner, the late Surgeon-General, Dr. J. D. Baxter, and the present Surgeon-General, Dr. Charles Sutherland, to whom he wishes publicly to express his gratitude. He also desires publicly to thank the Indian agents, physicians employed at the Indian agencies, and army surgeons, who have coöperated with him and advised him, and without whose generous assistance the studies could not have been made. The data were obtained in the face of the greatest obstacles, for Indians are ignorant, superstitious, prejudiced, and suspicious, and the time required in many instances was considerable, perhaps more than was warranted by the results to be obtained. From twenty-eight Indian agencies and army posts interesting facts were gathered, and since all the correspondents were in immediate communication with the Indians, some of them for many years, and all being entirely reliable, the information may be considered trustworthy. The Report of the Indian Commissioner for 1890 was also freely consulted, and was the source of much valuable information.

The subjects upon which information was sought included menstruation, conception, gestation, parturition, the puerperal period, the menopause, sexual appetite, pelvic disease, including venereal and malignant diseases, and a variety of kindred topics. In children the great frequency of glandular, including venereal, disease was noted, and the great mortality among infants. Puberty was reached in the southern tribes—the Apaches, Mojaves, and others—quite early, the average in a given number of Apaches being $12\frac{3}{5}$ years. In the northern tribes it was reached later, the average in a given number of Cheyennes and Arapahoes being 17 years. In a large number of Sioux the average age was 15.11 years. In most of the other tribes the average age was under fifteen, and it is believed that savage life *per se* neither hastens nor retards puberty, but that climate, occupation, and hereditary tendency were the factors of greatest importance.

The advent of puberty is celebrated by barbarous dances in some of the tribes. At the Quabaw Agency (Ind. Ter.) the "stamp dance" is thus celebrated. At Round Valley Agency (Cal.), the menstruating girl joins in a furious dance with older women, keeping it up until thoroughly exhausted. At the Neah Bay Agency (Wash.) the menstruating girl fasts three days, then is stripped naked and

[1] Abstract of a paper read before the American Gynecological Society at Washington, D. C., September 23, 1891.

washed in a stream in the presence of her friends and relatives. After this her parents give a *pil potlach* (giving away of blood), which is very disgusting, and is said to be somewhat of the nature of a birthday party.

With very many Indian women, especially the more degraded, the coming, course, and going, of menstruation were alike matters of indifference; they neither knew nor cared as to its duration. At four agencies the duration had been observed, and the limits given were two and six days. Seldom was there any pain in menstruation, though in some of the tribes it was said to be present with the first menstruation, but rarely afterward. Among the civilized Indians painful menstruation was not infrequent. The quantity of blood lost at menstruation was almost invariably a matter of indifference. Only a single case of amenorrhea was reported.

The menopause seldom causes any trouble. The age at which it comes shows as wide a diversity as it does among civilized women, and there was also the same variety as to duration. It may come abruptly, or it may require several years.

Marriage is said to be mainly a matter of convenience or inclination in most of the tribes, with nothing especially serious or binding about it, either party leaving the other as the notion may prompt. Polygamy is still common in some of the tribes, though the Government is endeavoring to break it up. Virtue and chastity are ignored altogether, or but lightly esteemed, in all but a few of the tribes. A change for the better in such matters is most marked, and most gratifying in some of the localities that have been under educational and religious influences. Cherokees are said to be more virtuous and more strict in regard to the marriage relation than whites.

Among the Klamaths (Oregon) young men are not infrequently married to old women.

Among the Crows and Assiniboines marriage arrangements are between a girl's parents and her suitor. The latter pays a horse for her, or some other object of value; the girl then measures the man for a pair of moccasins as a sign of acceptance, goes to his lodge, and is henceforth his wife. The marriage and divorce customs among the civilized Cherokees are much the same as among intelligent whites. The ceremony may either be a simple agreement between the man and the woman, or the more formal one of the Church or the State.

Marriage in most tribes is consummated very early in life, at seventeen or under, in many cases almost as soon as puberty is reached. Conception and gestation are favored in a majority of the tribes by an ardent sexual appetite and an out-of-door life, and large families of children are of frequent occurrence. Abortion seldom occurs as the result of the severe labor and other trials to which Indian women are all subject, but is common enough as the result of syphilis and criminal interference. Among the more degraded and physically inferior tribes the families of children are small. In almost all the tribes the infantile mortality is very great. The struggle for existence on the part of an Indian baby is a severe one. Some of the women drink decoctions of certain herbs to prevent conception. The Crows and Assiniboines use the most violent means for producing abortion. One of these consists in thrusting a sharp stick into the vagina and womb, thus rupturing the ovum. Another consists in causing the patient to rest her belly against the top of a stake driven into the ground, and about two feet high, and to whirl around upon this until the fetus is expelled. In yet another the patient lies on the ground upon her back, a large board is laid across her belly, and upon this two or three of her female friends stand or jump until the blood gushes from the vagina; or the belly is kneaded or tramped upon until the fetus is expelled.

Among these Indians last mentioned, when a baby is born the umbilical cord is cut with a *new* butcher-knife, the stump is well greased, and the infant is then thrust into a laced sack made of blue cloth, containing pulverized bull's manure, or the inside bark of the cottonwood tree. This lining, with the child's discharges, is changed three or four times daily. When the stump of the cord drops off it is preserved in a beaded pouch, and worn about the neck or waist as long as the person lives.

Parturition is usually a natural and easy process with Indian women. One of my correspondents graphically said it was about as easy as for a cow to have a calf. With many women no assistance is required or tolerated. With others, midwives are employed, and these manifest varying degrees of ignorance and superstition. Occasionally an herb-doctor will be called to attend a woman in confinement, but as a rule no man, whether a physician or not, is expected or allowed near a woman at such a time. Where the Indians are becoming educated and civilized they are gaining more and more confidence in white physicians, and occasionally one will be called to attend a confinement, especially if any complication has arisen. The favorite position during labor is the kneeling one, the arms, chest, and head resting upon a support of some character, but by many the squatting position is preferred. The ease with which delivery is accomplished in these positions, and the simplicity of the whole procedure, is not without suggestiveness to those of us that are endeavoring to carry out the multitudinous details of modern antiseptic midwifery. The lying-in chamber and the lying-in bed, for the tribes that have had little contact with civilization, do not exist.

Delivery takes place in the open air, in the bushes, by the side of a stream, perhaps when the tribe is on a march. The regular duties of the squaw are not long interrupted by parturition, and if her party is on the march she hurries on to overtake them after the birth of her baby.

In some tribes it is the custom to aid in the expulsion of the placenta by tickling the parturient's nose, thus provoking sneezing.

Among the Sacs and Foxes the placenta is wrapped in the blanket on which delivery took place and secured to a tree to keep it from wild animals. Should a wolf or coyote eat it, it is believed that the child would resemble such an animal, and eventually be devoured by it. The placenta must not be thrown into the river, lest the child should resemble a fish, or be drowned and eaten by fish.

The accidents of parturition are few, occurring perhaps as frequently as in the lower animals. The physicians at the agencies have reported cases of faulty presentation, retention of the placenta, and rupture and procidentia of the uterus. The Indians are just beginning to appreciate the value of skilled assistance for such emergencies.

Puerperal diseases are said to be unknown among Indians. Malignant disease is of rare occurrence, especially among the full-bloods. Cancer of the breast was reported, but not of the uterus. Of course, it is possible that the latter might exist, unknown to any but the patients, owing to their extreme reticence concerning disease of the genital organs. For the same reason it is impossible to say to what extent pelvic disease may exist among these women. Cases were reported in which there was deformity of the uterus, ovarian pain, abdominal dropsy, leucorrhea, and gonorrhea, so that it cannot be said that pelvic disease does not exist among them. It is probable that they are less susceptible as well as less sensitive to such diseases than civilized women. Those that are becoming civilized, or are already civilized, suffer from pelvic disease to about the same extent as the whites. Venereal disease was said to be very prevalent, and doubtless it has much to do with the feebleness of the children and the high rate of mortality among the infants.

CONCLUSIONS.

I. PUBERTY.—The mere fact of living in a savage state has not much to do with the early or late appearance of puberty. The Apaches and Mojaves of the hot and desert regions of Arizona mature young, but so do the females of Southern Europe and of the tropics; the law is general that both animals and plants mature early under a tropical sun. The females in the northern tribes—the Cheyennes, Arapahoes, Crows, Assiniboines, and Sioux—develop more slowly, as is the case with women in Northern Europe.

II. PHENOMENA OF MENSTRUATION.—Savage life with its vicissitudes and hardships does not usually interfere with the regular recurrence of the monthly flow. Influences that would disturb or check it and possibly produce permanent injury to a woman in civilized life, seem to have no such effect upon Indian women. Excessive menstruation is practically unknown. On the other hand, there are occasional instances of dysmenorrhea or amenorrhea in connection with disease or deformity of the pelvic organs, so that savage life does not necessarily furnish immunity from such experience.

III. THE MENOPAUSE.—Indian women are exceptionally free from the nervous and vascular disturbances that so commonly accompany the menopause in civilized women. The duration of the menopause varies as greatly as it does in civilized life. It usually comes between the fortieth and fiftieth years, but not infrequently is delayed beyond the fiftieth year. Many gestations occurring in rapid succession, continuous hard work, and the exposure and physical suffering incidental to a savage life do not tend to shorten the menstrual and child-bearing periods.

IV. MARRIAGE AND THE SEXUAL APPETITE.—The social condition of Indian women is an anomalous one for this age and country. They must bear the burdens, do the drudgery, bring forth and rear the children, and then, perhaps, be cast aside at the merest whim of their husbands. Marriage among American Indians means, as a rule, communism, polygamy, unrestrained lust, according to circumstances—all of which must, of course, be abandoned as they emerge into civilization. Sexual appetite in Indians is the uncontrolled and uncontrollable desire of the wild beast, or in women of the degraded and debilitated tribes it is an indifference, except as it may be associated with the idea of gain.

V. CONCEPTION AND GESTATION.—The habits and manner of life in the more vigorous and well-developed Indian women are favorable to fruitfulness. But the facts that so many children die in infancy, and that the restraints of civilized life are fatal to so many more, show that the race is not a hardy one. The unhygienic condition of the homes in many tribes, their filth and degradation, and in others the frightful abuses of the abortionists, are further tending to weaken the race and impair its future.

VI. PARTURITION.—The ease with which parturition is accomplished among Indians is an interesting fact. It must not be overlooked that the squatting or kneeling posture that they assume during labor is more favorable to muscular effort than the positions with which we are familiar in the lying-in

chamber. This is a suggestive fact. So, also, is the apparently total absence of puerperal disease among Indians. This is the result of pure air and plenty of exercise, and not of antiseptics or even ordinary hygiene. The quick recovery and return to their usual duties of Indian parturients also suggests the possibility that we sometimes unnecessarily make invalids of our obstetric patients. Accidents occasionally occur, just as they do among animals, Nature's work being sometimes far from perfect. This means death to the mother or child, or to both, unless an intelligence beyond that of the savage can be summoned to avert it.

VII. Pelvic Disease.—That pelvic disease has not been treated among Indians does not prove that it does not exist. Those diseases that result from infection, deformity, mal-development, and faults of circulation probably exist, but they will go untreated, and more or less unheeded, until the suffering caused by them becomes keener and confidence in educated physicians stronger. The malignant diseases of the reproductive organs are almost unknown among Indians. This shows that neither privation, nor hard work, nor exposure, nor giving birth to many children, necessarily result in the neoplasms that so often afflict civilized women.

VIII. Venereal Disease.—Both local and constitutional forms of venereal disease abound among Indian women. The frequency of syphilis, coupled with the great mortality among infants, and the great prevalence of glandular and pulmonary disease among many of those that survive infancy, are evidences of the inroads that venereal disease has made upon Indian vitality.

Finally, Indian women in the savage state undergo less physical suffering in connection with the reproductive apparatus than do civilized women. As a rule they menstruate, bear children, and pass the menopause with the minimum of discomfort. This is due to three causes: (1) Natural or racial insensitiveness compared with the far more sensitive Caucasian; (2) abundance of exercise; (3) life in the open air. With its complex conditions, civilized life will always present obstacles to the performance of the functions peculiar to women with the same ease with which they are experienced by savages, and when Indian women exchange the savage for the civilized state they must necessarily adopt also some of the ills that are inseparable from the latter.

The Inter-Continental American Medical Congress.—The Committee on Permanent Organization of the Inter-Continental American Medical Congress will meet at the Lindell Hotel, St. Louis, October 14, 1891. It is intended at this meeting to (1) adopt a constitution, (2) elect permanent officers, domestic and foreign, (3) select time and place of meeting. Members of the auxiliary committees of the different States are invited to attend.

RETARDED HEREDITARY SYPHILIS.[1]

By ROBERT B. MORISON, M.D.,
Dermatologist to the Johns Hopkins Hospital Dispensary.

For some years Fournier and his followers have kept constantly before the minds of syphilographers the possibility of syphilis remaining so latent as an hereditary disease in the human being, that it often does not appear until long after birth. Symptoms of this late-appearing form of syphilis are coming more and more to be recognized, and, when followed by cure after treatment, seem to point to the fact that a correct diagnosis has been made. Fournier, in preparing his statistics, calls especial attention to patients whose parents were known to have been syphilitic. He does not place so much value on those cases in which there is a doubtful previous history. Nevertheless syphilis is considered hereditary, if it be possible to exclude the certainty of its acquirement after birth. It becomes retarded hereditary syphilis if the child is born apparently healthy.

In my dispensary and hospital practice I have lately made a habit of recording as retarded hereditary syphilis those cases of children said to have been born healthy, but which had gradually become sickly, fretful, with their teeth unhealthy, with ulcerations on the head, buttocks, or nails, and in whom there is an *inaptitude native à la vie*—the "descendant indirecte" of Fournier. I have generally been unwilling to trust the previous history of the parents as given by themselves; therefore in cases in which it is justifiable they are put upon antisyphilitic treatment. The results have been satisfactory—more so than when such cases were counted among the scrofulodermata and dosed with all sorts of tonics, including cod-liver oil.

In looking over the last year of dispensary practice I find that out of 1887 cases treated, there have been 31 put down as retarded hereditary syphilis and 5 as scrofuloderma. The diagnosis of the latter cases was made after want of success with antisyphilitic treatment. Eight years ago all such cases were included by me under scrofuloderma. Among the negro children, of whom I see a great number and in whom the symptoms are never very distinct, mercury acts especially well. Under its influence their bones harden and straighten and their glands become less marked. But since in the healthy negro the glandular system is better developed than in the white, the size of the glands does not play an important factor in the diagnosis. In private practice it does not seem so hard to get at the true and previous history of the parents, especially of the father.

---

[1] Read at the meeting of the American Dermatological Association held in Washington, September, 1891.

In December, 1890, a young lady, aged twenty-seven, was brought to me by a country physician. He had treated the father of the lady as a young man, before marriage. The history of the father's disease was without doubt that of syphilis. Several of the children had died immediately after birth. The father was never well and the mother had been an invalid since marriage. Fifteen years ago the daughter in question, who was then twelve years of age, suffered much from so-called growing-pains, nodules appearing upon each tibia. Her teeth became so bad that all were removed. She had the syphilitic aspect that the English dwell upon—the constant restlessness of the eyes, with dark lines underneath them; the clay-like color of the complexion; pale, thickened lips; absence of teeth, and a small quantity of dull, unhealthy looking hair. Ulcers formed on the legs, arms, and body soon after puberty, and they have been coming and going, healing and breaking down, for these fifteen years. She had taken many medicines in many places, including much mercury, potash, and arsenic. After treating her for several months with such remedies, I stopped all internal medicine, excepting a little quinine, and gave her as a dressing a saturated solution of pyoktanin in distilled water. She lives at a distance, and therefore I seldom see her, the last time being in June. At that time, under the influence of the pyoktanin the ulcerations had all healed, no new ones appearing. She said that she had not been so well for many years.

This case seems to me one of retarded hereditary syphilis, and it is instructive, inasmuch as none of the antisyphilitic remedies seem to have been so active as usual, though how far the disease might have gone without them cannot be determined. Their want of activity in this case does not seem to impair the diagnosis, since mercury and potash cannot be given in certain cases of acquired syphilis, although there is no doubt of the diagnosis.

The condition of the teeth upon which Fournier dwells at so much length cannot, it seems to me, be of so much importance for us in our well-to-do classes as it is in Europe. The care taken of the teeth by our people and the skill of our dentists, seem in many cases to remove the chance of disfiguration that usually follows hereditary syphilis. At least it has been my experience that the appearance of the teeth in people of this country is less a factor in diagnosis than it is in Europe.

Nevertheless, the teeth do frequently show characteristic changes that point to a previous history. In one well-born family I found the teeth of all the children over sixteen notched, discolored, and irregular. The father had syphilis before marriage, the mother had been an invalid ever since. There were other symptoms, such as ill-defined pains, glandular enlargement, and chronic sore-throat. Nothing relieved them so much as small doses of mercury. All these children were said to have been born healthy, and remained so for many years afterward.

It seems to me that it is proper for a physician to look upon syphilis as the latent cause of a great many cases of uncertain nature. We cannot prove its existence by the presence of any yet discovered bacteria, though some microscopists claim that they can make a diagnosis of syphilitic tissue as readily as they can that of cancerous or tuberculous tissue. The use of the microscope is not necessary when the symptoms disappear under treatment. The prognosis seems to me to be much better in retarded hereditary syphilis than in hereditary syphilis. A child born with hereditary lesions seems to stand less chance for life than the one in whom they appear in later life.

MEDICAL PROGRESS.

Nephrectomy for Carcinoma. — Krönlein (*Corresp.-bl. für Schweizer Aerzte*, August 15, 1891) presented to the Society of Physicians of Zurich, a kidney obtained from a woman, forty-four years old, who for a considerable time had presented symptoms of floating kidney. Subsequently hematuria manifested itself, and a large tumor was detected in the right side of the abdomen. Operation having been decided upon, a lumbar incision was made and the kidney separated from the peritoneum without injury to the latter. In isolating the pedicle the renal vein was torn. The vessel was speedily caught and ligated. Drainage provided for, the wound was sutured. The case pursued an even and afebrile course. There were no uremic symptoms. The tumor had not invaded the connective-tissue capsule of the kidney, so that the prognosis was favorable. Five weeks after the operation, the patient was dismissed, cured. Microscopical sections showed the tumor to be a papillary carcinoma. Krönlein stated that he had removed the kidney in three cases for carcinoma.

Acute Yellow Atrophy of the Liver. — Burckhardt (*Corresp.-bl. für Schweizer Aerzte*, August 15, 1891) reports the case of a widow, thirty-two years old, who, after profound emotional depression, developed jaundice, followed in turn by delirium, with but slight elevation of temperature, death taking place in coma. The autopsy confirmed the diagnosis of acute yellow atrophy of the liver. Burckhardt takes occasion to controvert the view that acute yellow atrophy is always the result of phosphorus-poisoning. In the former, the primary enlargement of the liver and the colicky pains of the latter are wanting, while the maniacal manifestations of acute atrophy are absent in phosphorus-poisoning. Examination has thus far failed to find phosphorus in the organism in acute yellow atrophy. From the absence of fever in, and the sporadic appearance of, acute atrophy, Burckhardt is unwilling to place it in the category of infectious diseases. He would rather ascribe the symptoms to the absorption of abnormal products developed in the course of parenchymatous inflammation of the liver induced by an unrecognized noxa.

SATURDAY, OCTOBER 3, 1891.

THE CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS.

Despite the prostrating temperature under which the meetings were held, and notwithstanding the sad effects of the drinking-water, there was a fine attendance of members and visitors from all parts of the country and from Europe, and the general verdict concerning the Congress is one of complete satisfaction. In attempting any critical estimate, there at once stand out two salient phases that distinguish the disposition and labors of all the bodies. The first refers to the fact of the work done; the second to its conservative character.

If anyone went to Washington with the expectation of having "a good time," he must have felt much out of place there. It was almost painfully apparent that these men were pledged to work, not to pleasure. There was everywhere an air of seriousness and earnestness, undoubted and persistent. The meetings were called to order on time, and without form or sentiment the business proceeded as if the recess had been but three minutes, instead of three years. The addresses of the presidents of the different associations were concise and to the point; each seemed to feel himself an introducer who dared not long delay the introduction. Taught by experience, by necessity, and by desire, verbosity was "conspicuous by its absence;" and the rigid condensation and epitomization of results, whilst giving severe work for thought and attention, allowed the freest expression to the many and diverse-minded sharers in the great debate. For downright tireless work, Drs. Judson, Ridlon, and their associates must be awarded the prize. By the reading of sixty-seven papers (twenty-four or more on Pott's disease!) it is to be hoped that the ghost of good old Dr. Pott was enlivened, and that no member by long sitting arose with any but the most temporary of spinal curvatures or spastic paralyses.

It is also equally plain that the quality or general character of the work done indicated the dominance of discrimination, criticism, or conservatism. The fine oration of Dr. Mitchell struck upon the central idea of modern medical science. Progress in instrumental precision is but the exponent of progress in mental precision, both being necessary prerequisites of therapeutic and prophylactic power. There was at this meeting no pronunciamento of ill-digested and unproved theory such as harmed the Berlin Congress, and unjustifiable enthusiasm was held in tightly reined check by the clear-cut determination to adhere to fact, to test and re-test with cold judgment. It is evident that to meet coming problems and to square itself with the scientific spirit that is filling and controlling all human studies and labors, Medicine must look to her premises and foundations, re-prove supposed axioms, strengthen bases, and scrutinizingly examine every part of her growing body of truth.

In accordance with the new spirit there was observable a saner return from the bacteriomania and pyophobia of the immediate past; it begins to become apparent that all human ills are not caused by "bugs," nor curable by corrosive sublimate. According to Prof. Welch, it would even seem that the frightful pessimism of the latter-day pathology may give way to something of optimistic trust in a goodness even behind morbid processes, and in a purposive wisdom even in suppuration. Essentially the same great truth was reached by Prof. Roswell Park, who, with clear logic, summarized in his able way the advanced science of to-day as to the principles of sepsis, antisepsis, and asepsis.

"THE NEWS" AND THE CONGRESS.

It is with pardonable pride that The News calls the attention of its readers to its work in reporting the four days' sessions of each of the fourteen asso-

ciations and of the general meetings. Despite the many difficulties and the great labor necessarily attending such an endeavor, it is believed that no item of scientific interest will fail of mention, and that exceptional accuracy and authority have been obtained. For the unvarying and unexpected kindness manifested to THE NEWS, its readers will join us in grateful recognition to the secretaries and society members who in varied ways have generously aided us.

But following the meager reports that at best are but glimpses of the feast, THE NEWS promises its readers the substantial reality of a large number of the original papers, to be published in full as soon as space can be found. The number of such manuscripts that without solicitation have been kindly given us, though creating for us a genuine "embarrassment of riches," will doubtless make those of our readers who could not attend the Congress feel somewhat as if it was hardly necessary to have done so.

WASHINGTON AS A MEETING-PLACE.

IT is with regret that one must express a single but weighty objection to the city of Washington as an appropriate meeting-place, at least for medical conventions. For probable reasons that we should tremble to detail, the gastro-intestinal apparatus of the political congressman must be more resistant to the Washingtonian microörganisms of drinking-water than that of the medical congressman, or the former would long ago have voted a score or more of millions to supply a less noxious quality of water. At one dinner-party in the course of the recent Congress, but four out of the large number of those invited were able to be present, and probably from 50 to 75 per cent. of those attending the Congress were afflicted with a viciously severe diarrhea.

The preceding criticism becomes the more pointed because in other respects—the beauty of the city, the numerous objects of interest to the visitor, the commodiousness and excellence of her hotels, and the hospitality of her citizens—Washington is exceptionally well adapted for the purpose in question.

To repeat the feeling language of one of the afflicted—from a private letter of one of our great surgeons: "What a scandalous reflection upon this country's intelligence that citizens cannot visit the Capital without being prostrated by disease due to filthy water! If there is pure water within one thousand miles of the city the National Government ought to secure it."

Will not our colleagues who are also governmental officers or *Geheime-Räthe*, "govern themselves accordingly."

THE REPORT OF THE COMMITTEE ON FRACTURES OF THE FEMUR.

IN the last number of THE NEWS, containing the full report itself, there was a failure to mention that the report of the Committee on Fractures of the Femur, of which the chairman, DR. STEPHEN SMITH, was virtually the author, was unanimously and heartily adopted by the Surgical Association. Emanating from a committee the members of which are men of such distinction and authority, coupled with the fact of the intrinsic importance of the subject and its medico-legal bearings, this clear and precise statement upon the peculiarly involved and difficult points discussed, becomes of exceptional value and significance, to both the medical and legal professions at large.

SOCIETY PROCEEDINGS.

AMERICAN SURGICAL ASSOCIATION.

Twelfth Annual Meeting, held at Washington, September 22, 23, 24, and 25, 1891.

(Continued from p. 367.)

FOURTH DAY—SEPTEMBER 25TH.

The committee to which was referred the suggestions in the President's Address offered the following resolution, which was adopted:

"*Resolved*, That the President appoint a committee, with authority to confer with the friends and admirers of Professor S. D. Gross, and with the profession at large, for the initiation of a movement on the part of the Association, having for its object the erection of a monument to Dr. Gross in the City of Washington."

The President announced that he would name the committee in a few days.

DR. LEWIS A. STIMSON, of New York, then read a paper on the "Treatment of Fractures Involving the Elbow-joint," which appears in full elsewhere in the current number of THE MEDICAL NEWS.

In the discussion, DR. N. P. DANDRIDGE, of Cincinnati, referred to two cases occurring under his observation. In one, of simple fracture from great violence, in which the arm was treated in a position of almost complete extension, non-union occurred. In the second, after fracture at the elbow-joint a projection of bone pressed upon the median nerve, causing severe pain and atrophy of the muscles in the distribution of the nerve. The case was seen three months after the accident. Removal of the bone was followed by relief of the pain, and a gradual restoration of the function of the muscles.

Dr. R. A. Kinloch, of Charleston, thought that in simple fractures about the elbow, if seen early, and the ordinary principles in regard to the treatment of fractures be applied, the result would be good. Probably in a large number of cases some restriction of movement was to be expected. The most important element in the treatment is the proper reduction of the fragments. This should be done at once, an anesthetic being employed if necessary. The proper reduction of the fragments is determined by testing the functions of the joint. The second indication is to retain the fragments in proper position. If the case is treated with intelligence, it makes little difference how the splint is applied, or whether the forearm is flexed or extended. The position is to be determined largely by the peculiarities of the individual case. Dr. Kinloch was inclined to favor the extended position. He thought that early passive motion did more harm than good. If the parts have been properly reduced and held in position, and there is no danger of subsequent trouble, passive motion may begin in three or four weeks.

Dr. E. M. Moore, of Rochester, said that in a fracture of the internal condyle, the cause of the displacement is the flexor muscles, and to relax these muscles the arm should be placed in the flexed position. In fractures of the external condyle he has also found this position preferable; for when the forearm is flexed, the dense fascia on the front of the arm is rendered tense, and acts as an efficient splint. He objected to the extended position exclusively. He treats all fractures about the elbow-joint, with the exception of fractures of the olecranon, in the rectangular position for the first ten days or two weeks. Lateral splints are used with the object of pressing the fragments together after the tenth day. The fracture is dressed every other day; the angle of the splint being changed a little each time, so that the arm passes from almost complete flexion to almost complete extension. Since adopting this mode of treatment he has never had the slightest difficulty in any case.

Dr. James McCann, of Pittsburg, said that it was not always easy to determine the exact nature of fractures about the elbow-joint, even with the patient under the influence of an anesthetic. While the patient is under the anesthetic the preliminary dressing should be applied. He recommended the use of the internal angular splint, preferably that suggested by Dr. Packard. He did not favor the use of passive motion at an early stage. Passive motion should not be resorted to prior to the twentieth day.

Dr. John B. Roberts, of Philadelphia, thought that the teaching advocated by some of the speakers was to a large extent dangerous and incorrect—that is, that injuries about the elbow-joint should be treated in the flexed position. He believed that, except in unusual cases, these fractures should be treated in the extended position, according to the doctrine advocated by Dr. Allis; in this way the gun-stock deformity is avoided. He now approached fractures of the elbow with the same certainty of getting a good result as he did fractures of the lower end of the radius.

Dr. S. H. Weeks, of Portland, dwelt upon the fact that, with few exceptions, all authorities advised the flexed position in the treatment of fractures about the elbow-joint. Until there was more positive evidence of the value of the extended position, he thought it better to continue to treat these fractures in the flexed position. After two weeks of treatment, he employed passive motion in a modified way, the splints are removed and the joint moved gently, but not sufficiently to cause pain. This simply alters the relations of the parts without doing any damage.

Dr. L. McLane Tiffany, of Baltimore, thought that as good results were reported from various dissimilar methods of treatment, we must conclude that the prognosis of elbow injuries depends more upon the patient than upon the surgeon. Fracture of the elbow is rare in adults and common in children; and in children, with reasonably good treatment, there should be a good result, so that by the time adult age was reached the motion would be almost perfect. In the adult, the prognosis is more grave. He had had good results both with the flexed and with the extended position. In compound fractures, the secret lies in the relief of tension, irrespective of the apparatus employed. Incision up and down the arm through the strong fascia should be made as freely as required.

Dr. Albert Vander Veer, of Albany, read a paper on "Retro-peritoneal Tumors: their Anatomical Relations, Pathology, Diagnosis, and Treatment," the full text of which will be published in the *American Journal of the Medical Sciences*. He reported three cases, in two of which the tumors originated in the capsule of the kidney, and in the third in the supra-renal capsule. Retro-peritoneal tumors, even when typical, can never be said to be absolutely benign, for, although they may not give rise to metastases or to infiltration of surrounding tissues, or when removed they may show no tendency to recurrence, yet from the great size that they attain, the discomfort that they occasion, and from the tendency to undergo degeneration that they exhibit, they cannot be considered innocent. The tumors found in the kidneys of young children are, for the most part, mixed tumors, chiefly myo-sarcomata. In the diagnosis of retro-peritoneal tumors, diseases and neoplasms of the uterus and its appendages, of the liver and gall-bladder, of the spleen, pancreas, and of the kidney, as well as abdominal aneurisms and tumors of the mesentery and of the abdominal walls, are to be excluded. Without operative interference, a fatal termination is inevitable. The mean duration of life after the discovery of the tumor is not more than nine months. The results of operative interference are promising. The immediate mortality following operations is necessarily high. The fatality has been greater after incomplete operations than after those in which the tumor was completely removed. Czerny states that "in all cases operative interference can safely be undertaken; when the tumor is no longer encapsulated, the incision had better be closed; otherwise the growth should be enucleated."

Dr. De Forrest Willard, of Philadelphia, read a paper on "Intra-thoracic Surgery: Bronchotomy through the Chest for Foreign Bodies Impacted in the Bronchi," which is to appear in the *American Journal of the Medical Sciences*. He detailed a series of eight experiments made upon dogs by the introduction of foreign bodies into the air passages, followed by various procedures for the removal of the bodies. These experiments showed that in dogs the bronchus can be reached through the chest-walls,

from in front or behind, but being in such close proximity to important structures incision is difficult and dangerous. The operation is attended with great shock from collapse of the lungs, and, until the technique is improved, is liable to result in immediate death. Collapse of a healthy lung is more serious than collapse of a diseased lung. The difficulties and dangers of the operation are shock, suffocation from pulmonary collapse, pulmonary hemorrhage, injury of the pneumogastric nerve, and exaggerated movement of the root of the lung induced by the great dyspnea. Closure of the bronchial incision takes place slowly, and is attended with danger. To leave it open would be followed by the entrance of septic air into the pleural cavity, increasing the existing pneumothorax. Although a foreign body in the bronchus can be reached by bronchotomy, the removal of the body is hazardous. A successful issue seems at present problematical. Should a foreign body in the bronchus fail to be expelled, its retention is attended with danger, though the obstruction be but partial. There is immediate or remote risk of inflammation. Low tracheotomy is then advisable; it adds little to the risks, and affords a ready means of escape, if extraction is not feasible. Subsequent dangers are dependent upon severe and prolonged instrumentation rather than upon the tracheotomy. Spontaneous expulsion is facilitated by tracheotomy. Tracheotomy is permissible even when a foreign body has long been imprisoned in a bronchus. The question of tracheotomy is largely dependent upon the form, size, and character of the foreign body. The term bronchotomy should be limited in application to an opening of the bronchus. The risks from thoracotomy and bronchotomy following unsuccessful tracheotomy are much greater than the dangers incurred by permitting the foreign body to remain.

In the discussion, DR. J. R. WEIST, of Richmond, said that from a study of one thousand cases in which foreign bodies were impacted in the bronchi, he had reached the conclusion that the chances of the patient were better if left alone than if an operation, such as bronchotomy, was performed.

DR. S. H. WEEKS, of Portland, thought that in these cases tracheotomy should be performed, as this affords a chance of reaching the foreign body, and also offers a chance for its spontaneous expulsion. It occasionally happens that the body is forced up against the vocal cords and then falls back, or else suffocates the patient before relief can be afforded. He reported the case of a child, ten years old, that had gotten into the trachea a screw-cap that was used to close a pocket-flask. The screw-cap had been in the trachea for several days before the patient came under observation. The trachea was opened, and the patient suspended, but the foreign body did not escape. The patient was then placed in the horizontal position, and an attempt made to remove the cap with forceps. It could be felt, but could not be grasped. After working unsuccessfully for some time, the patient was again suspended, and the attempt with the forceps renewed, and at once the body was grasped and removed. The patient made a perfect recovery.

DR. KINGSTON, of Montreal, reported a case in which he had removed an artificial incisor tooth, with its attachments, from the trachea, where it had remained for three months. The operation necessitated prolonged manipulation, but was followed by no bad results.

MR. HOWARD MARSH, of London, thought that on account of the danger of leaving the foreign body in the bronchus, the uncertainty as to the possibility of removal until the attempt is made, and the safety of tracheotomy, this operation should be performed. In all cases it gives the patient a chance, when otherwise he would perhaps have none.

MR. ARTHUR EDWARD DURHAM, of London, agreed that the operation through the chest-wall was a dangerous and doubtful procedure. The more he saw of these cases the more satisfied was he, as the result of considerable experience, that the proper thing to do when there is clear evidence that a foreign body is impacted in the bronchus, is to open the trachea low down, and endeavor to remove the foreign body, or to facilitate its spontaneous expulsion.

After extending a vote of thanks to the retiring President, the Association adjourned, to meet in Boston, Mass., in June, 1892.

AMERICAN GYNECOLOGICAL SOCIETY.

Sixteenth Annual Meeting, held at Washington, September 22, 23, and 24, 1891.

(Continued from p. 370)

SECOND DAY—SEPTEMBER 23D.

DR. A. REEVES JACKSON, of Chicago, delivered the President's Address. He revieved the work of the Society in the past, and referred with much feeling to the recent death of Dr. Fordyce Barker, one of its founders and its first presiding officer. He had occasion also to mourn the death of Dr. David Humphrey Storey, of Boston, an honorary member, and Dr. George H. Lyman, one of the founders.

Reviewing the field of gynecology during the fifteen years of the Society's organization, he pointed out how the advocates of certain operative procedures had become extremists. The total extirpation of the uterine appendages was a most striking instance of this tendency. He considered it a crime to remove the ovaries and tubes when simpler treatment could be adopted. He protested against the too frequent examinations of the pelvic organs of young girls and unmarried women, and condemned the practice of publishing hasty and immature reports of surgical work that had not undergone the test of time.

DR. WILLIAM H. BAKER, of Boston, read a paper on "Cancer of the Cervix Uteri: Result of its Treatment by High Amputation," in which he referred to the importance of tracing the future history of cases. The specialist sees comparatively few cases sufficiently early to accomplish much by a radical operation, because the early symptoms are not marked, and the hemorrhage and leucorrhea are supposed by the patient to be incident to the menopause, and because in many cases the physician fails to recognize the importance of the condition, or, recognizing it, lacks faith in its successful removal. Of ten cases reported in 1882 as having been operated on without a death, eight were then living and well. In 1886 six of these were then living and well, or about 60 per cent., after a period of from four to eight years. At the

present time 50 per cent. of the original cases are living and well, after a period of from ten to twelve years.

In a second series of cases operated on from 1882 to 1889 there was no recurrence of the disease in 62½ per cent. of the cases.

Dr. Baker emphasized the necessity of thoroughly cauterizing the raw surfaces after the removal of the growth by the knife. He claims for the high amputation, as compared with hysterectomy, greater safety to the life of the patient and longer respite from recurrence of the disease.

The following conclusions were formulated: All the disease should first be thoroughly removed with scissors or scalpel, keeping well outside the infiltration and apparently in healthy tissue; second, the wound should not be immediately closed, but every portion of it should be kept under observation until entirely healed; third, the thorough application of the cautery is an all-important factor in the success of the operation; fourth, it is often necessary to do some slight secondary operation to insure success; fifth, the cases must be under close observation for years.

In all cases of carcinoma of the cervix, when the uterus has not become fixed by an extension of the disease, high amputation, followed immediately by the application of the cautery, is the safest and best method of treatment. Vaginal hysterectomy should be reserved for cases of carcinoma primarily affecting the corpus uteri, or when the disease has extended to the corpus uteri without fixing the uterus.

Dr. John Byrne, of Brooklyn, believed that high amputation could be as completely performed with a delicate galvano-cautery knife as with the scalpel or scissors.

Dr. Thomas Addis Emmet believed in the high amputation, though in some cases of sarcoma it might be necessary to resort to total extirpation.

Dr. Henry J. Garrigues, of New York, read a paper on "The Best Posture in the Different Stages of Normal Labor." In deciding the posture to be occupied by a woman during labor one should take into consideration her comfort and safety, the child's safety, and the accoucheur's comfort, which again contributes to the mother's safety. While the child is passing through the bony part of the parturient canal, the semi-recumbent position on the back is best. The contraction of voluntary muscles and gravity coöperate with the contraction of the womb; the entrance of the head into the superior strait is favored; the stethoscope can easily be applied to the abdomen; manual pressure may be exercised on the womb. Sometimes a change of position is useful.

When the vulva begins to open, the patient should be turned on the left side and should lie horizontally, her thighs at a right angle with the trunk, and the legs and the lumbar region extended. All support should be taken from hands and feet, and chloroform should be given. In this position the os coccygis is free to recede backward, the genitals become visible and easily accessible, while the rest of the body remains covered, whereby exposure to cold is avoided; the patient does not see the accoucheur and has a feeling of being hidden. Abdominal pressure is limited; the fundus sinks down, so that gravitation works in a direction opposite to that of uterine contraction. The left lateral position affords a safeguard to the perineum and prevents the head from emerging too suddenly. During and after the expulsion of the placenta, the woman should be on her back, with the head low, a position well adapted to Credé's method. The kneeling, squatting posture is fatiguing, predisposes to fainting and hemorrhage, makes the use of the stethoscope difficult, nearly excludes any kind of protection of the perineum, and renders the use of chloroform impossible, though in cases of lingering labor it may be tried.

Dr. A. F. King, of Washington, thought that normal labors were the exception, rather than the rule, whence it was difficult to designate any definite posture as the best.

Dr. Sawyer, of Chicago, mentioned the case of a Piute Indian whom he had seen, whose child was born while she was standing erect.

Dr. W. Gill Wylie read a paper on "The Influence of Imperfect Development as a Cause of Uterine Disease." The most important influence at work in causing uterine disease is the tendency to restrict the physical development of our females just at the time when they are changing from girls to women. The generative organs are practically dormant until about the tenth year, when they begin to develop and make a large demand on the system up to about the sixteenth year. To insure full development during this period a girl must have a surplus of physical and nerve force. If, during this period of development, the girl is pushed at school or her force is used up by constant contact with older, intellectual persons, she is almost certain to have a leucorrheal discharge and dysmenorrhea, and an imperfectly developed uterus, with disease of the glands and follicles, which predisposes to catarrhal endometritis, the development of new-growths, such as carcinomata or fibromata; and if marriage and pregnancy follow, the labor is apt to result in laceration of the cervix, or the catarrhal condition is pretty certain to result in sterility. To prevent this condition of imperfect development the general health should be maintained, the bowels kept regular, and healthful play out-of-doors and pleasing mental occupation should take the place of an in-door life, forced cramming, and stimulating contact with older persons.

Dr. A. W. Johnstone, of Cincinnati, believed that if there were no infantile uteri there would be no lacerated cervices, and that quite a large percentage of cystic ovaries and diseased tubes were due to infantile uteri.

Dr. Henry T. Byford, of Chicago, presented a paper on "The Technique of Vaginal Fixation of the Stump in Abdominal Hysterectomy," in which he related his experience in twenty cases, with one death—a mortality of 5 per cent. The steps of the operation are as follows: 1, Ligating and suturing the broad ligaments; 2, separation of the bladder from the uterus; 3, placing the elastic ligature and pedicle pins; 4, ligating the stump and suturing the pared edges—all sutures and ligatures of the stump are to be left about four inches long; 5, removal of elastic ligature; 6, incision into the anterior fornix of the vagina; 7, turning the stump into the vagina; 8, suturing the bladder-peritoneum over the stump, so as to shut off the peritoneal cavity; 9, closure of the abdominal incision; 10, placing the clamp on the stump through the vulva, with the patient in the lithotomy

position; 11, checking oozing from the vaginal edges by means of dilute Monsel's solution and loose packing of the vagina with antiseptic gauze. Too much handling of the intestines is one of the chief dangers; in suturing the peritoneum over the stump, deep stitches are to be avoided, so as not to leave bleeding stitch-holes. Spurting vaginal arteries should be tied when severed.

Intra-peritoneal methods of treating the stump are inferior, because of the impossibility of rendering the stump harmless to the peritoneum, with the consequent unfavorable statistics. Total extirpation is too grave an undertaking, as statistics demonstrate. Ventral fixation is regarded as safe enough, but inferior to vaginal fixation, on account of the unnatural position of the cervix and the danger of hernia.

Vaginal fixation possesses most of the advantages of the other methods with few of the disadvantages. Its mortality is the lowest; its execution quite rapid; it need involve but little exposure of the intestines; it leaves the stump in a natural position, entirely outside of the peritoneal cavity; it leaves the smallest wound-surface in the peritoneal cavity; like total extirpation, it provides a safety-valve, in that there is an opening at the bottom of the peritoneal cavity, closed only by superficial catgut sutures; it preserves the portio vaginalis and the vagina unmutilated; bladder rents can be treated extraperitoneally, without displacement of the viscus; the necrotic stump is held off from the wounded tissues; perfect hemostasis is obtained.

Dr. Horace T. Hanks, of New York, read a paper entitled "Suggestions of Certain Rules to be Followed in the Effort to Prevent Mural Abscesses, Abdominal Sinuses, and Ventral Hernia after Laparotomy." Abscesses in the line of abdominal incisions after laparotomy tend to make tracks for later ventral herniæ. In trying to obviate the development of mural abscess incisions should be clean, the various layers being carefully separated; the lips of the wound should not be retracted with too much force or exposed to too long pressure; too hot water or too strong a germicide should not be applied to the lips of the incision; the abdomen should be rendered aseptic by means of a germicide dressing applied some hours before the operation. The operation should be aseptic. The dressing should be removed every second day. Before cutting the sutures the patient should wear a moist bichloride dressing for two or more hours; care should be taken that no sepsis is introduced into the wound when the sutures are withdrawn. No unnecessary punctures with needles should be made; the wound should not be strangulated by too tight tying of the deep sutures.

To avoid sinuses: a drainage-tube should never be used unless necessary; a tube should never be allowed to remain *in situ* more than twenty hours; the tube should be kept sweet and clean.

Ventral hernia can be prevented by a more careful apposition of the different layers of peritoneum, muscles, and fascia, care being taken not to strangulate the deeper tissues by suturing too tightly. Silkworm-gut sutures are to be recommended.

Dr. Emmet, of New York, believed that silver-wire suture should be used in preference to all others, because it enabled a more perfect coaptation of the edges of the wound. If the silk suture was used it was likely to have the effect of doubling the abdominal wall on itself, and producing a union between the peritoneum and the skin, which, he believed, in these cases was a frequent cause of hernia.

Dr. Byford, of Chicago, maintained that two important causes of abscess were sepsis and dead material in the wound. In an operation lasting half an hour there is apt to be a certain amount of laceration of the fatty tissue around the edges of the wound, and in order to get perfect union a certain amount of this wounded fat must be cut away, otherwise it will undergo necrosis. The worst abscesses that he had encountered were in cases in which he had used buried sutures. He preferred the silkworm-gut suture, introducing it with a curved needle, the suture describing a circle and preventing the peritoneum from pushing up into the wound.

Dr. W. Gill Wylie, of New York, stated that below the umbilicus the peritoneum is a loose tissue with little strength, that must be cleanly cut without being torn. The recti muscles are longitudinal muscles, and their transverse strength, excluding the facial covering, amounts to little. In opening the abdomen he would avoid that point and open in the linea alba. It was of vital importance to get perfect union of the deep fascia.

Dr. Thaddeus A. Reamy, of Cincinnati, read a paper entitled, "Some Clinical Testimony as to the Ultimate Results of Removal of the Uterine Appendages." The material on which the paper was based was restricted to cases in which there was a reliable history of the patient's condition for from two to five years after operation, excluding cases of ectopic gestation, tumors and malignant disease of the ovaries. The operations included 163 cases: In 144, both ovaries and tubes were removed; in 15, but one ovary was removed; in 7, such extensive adhesions and destruction of tissue by disease existed that the operation was discontinued after liberating, as far as possible, adhesions, the cases doing well; in 12, the appendages were removed for arrest of hemorrhage and growth of fibroid tumors (in none of these did the growth ascend above the umbilicus); in 6, for hystero-epilepsy (three of which were cured); in 3, for neurotic symptoms (1 cured, 1 improved, 1 made worse). Pyosalpinx was found in but 17 cases; parenchymatous salpingitis in 29; hydrosalpinx with disseminated cystic degeneration of both ovaries in 30 cases—of one ovary in only 26 cases.

Results: Forty cases were cured; 60 were improved in general condition; 30 were temporarily improved, but relapsed after a year or two; 10 were apparently worse after operation.

In every case in which both ovaries were thoroughly removed, menstruation ceased within six months, generally at once. In several cases uterine hemorrhage occurred subsequently, but not as menstruation. Reliable testimony from 44 married cases showed that in 14 the sexual appetite was extinguished with menstruation, in 7 it was lessened, in 16 it was not influenced, in 7 it was decidedly increased.

Conclusions: 1. Pyosalpinx does not exist in nearly so large a proportion of cases of pelvic disease in the middle and upper classes as is generally thought. 2. In cases of this class gonorrhea does not play nearly so important a rôle in the causation of disease of the tubes and ovaries as is generally believed. 3. In properly

selected cases, in which otherwise-incurable disease of the appendages exists, the results from surgical interference are not only satisfactory, but brilliant. 4. In properly selected cases the removal of the uterine appendages offers more promise for the relief of hystero-epilepsy than is generally conceded. 5. The practice should not be continued in the treatment of purely neurotic cases. 6. Many cases of manifest pelvic disease, including disease of the ovaries and tubes, which are cured by removal, could be as thoroughly and promptly and more satisfactorily cured by more conservative methods, without the sacrifice of these important organs. 7. Many cases reported by operators as cured are after a few years found to be no better off than before operation. 8. The arrest of menstruation after the removal of the ovaries in so large a number of cases tends to confirm the belief that the ovaries bear an important relation to this function. 9. The influence of the removal of the appendages upon the sexual appetite has heretofore not generally been properly stated. 10. The relation of this influence to menstruation and the psychoses that so often follow to mar the otherwise satisfactory results of this operative procedure must now be fully conceded.

Dr. Joseph Taber Johnson, of Washington, thought that the removal of the appendages for a small bleeding fibroid was most justifiable and saved the patient from the horrors of a subsequent hysterectomy. He agreed with Dr. Reamy that the neurotic cases were the most difficult to treat. It might be well to give such patients the chance of the benefit that might follow operation, but always with the full explanation that there was no certainty that it would succeed. He doubted the advisability of operating for dysmenorrhea, as there were many other methods of successfully treating this condition; he thought the operation should be restricted to cases in which there was positive disease of the tubes and ovaries determinable by palpation.

Dr. Gill Wylie, of New York, was surprised that Dr. Reamy had performed so many incomplete operations. In his experience of over four hundred operations for diseased tubes and ovaries he had never performed an incomplete operation, and without losing many patients. He had observed a return of menstruation in about 5 per cent. of cases, due in every case, he believed, to other conditions of the uterus not cured by the operation.

Dr. S. C. Gordon agreed with Dr. Reamy in regard to neurotic cases. He had observed that the symptoms increased at the period of menstruation; when everything else had been done without effect that could be done, he would operate. He was much opposed to the experimental method of treating these cases—curetting, tamponning, iodinizing, etc., for four or five years, in order to find out what the trouble was.

Dr. H. C. Coe, of New York, thought true menstruation after the removal of tubes and ovaries a very rare occurrence, but he was convinced that profuse uterine hemorrhages did sometimes continue for one, two or three years. He had operated three times on one woman to ascertain the cause of profuse hemorrhage, but could demonstrate nothing beyond the presence of firm adhesions. Several small nodules were removed from the stumps of the tubes, but no ovarian tissue was found. Persistent hemorrhage may be due to adhesions, or sometimes to cysts of the broad ligament, and in a large number of cases to hypertrophic endometritis, the uterus not undergoing ordinary atrophy.

Dr. Richard B. Maury, of Memphis, read a paper on "The Indications for Laparotomy in the Treatment of the Puerperal Fevers." He divided puerperal fevers into two great classes: 1. Those that are almost always recovered from. 2. Those that are almost certainly fatal. The first are frankly inflammatory, with a tendency to localization, retaining the characters of a simple inflammation. The others are strikingly infectious in character, reacting on the entire economy and accompanied by diverse manifestations in organs more or less remote from the starting-point of the infection.

The first class includes cases that begin as a metritis, with extension of inflammation to the appendages, and a resulting pelvic peritonitis. Some of these terminate by slow resolution; in others, suppuration ensues, pus breaks into the vagina or rectum, and recovery may soon follow; but often the patient dies, exhausted by hectic. It is in this class of cases that laparotomy gives the most hope of success. The second class includes cases of putrid infection from decomposition of placental remains, clots, etc.; also cases of purulent infection, accompanied by the same general and local phenomena as in the case of purulent surgical infection, with metastatic abscesses and emboli; lastly, pure septicemia, in which there is no proper localization. The indications for laparotomy in these cases are very doubtful. On the border-line between these two classes is puerperal metro-peritonitis. These border-line cases are most perplexing in deciding the question of operation, and it is in this class that the results of surgical treatment have been most discouraging.

Ancient disease of the uterine appendages is an important factor in childbed mortality, from peritonitis rekindled into activity by labor or the processes of involution. The symptoms present in such cases are essentially those of puerperal peritonitis, and it is clinically impossible to separate cases having such an origin from others in which there is a general septic infection incurred through wounds in the genital passages.

In the cases first described, the prognosis after operation will presumably be much more favorable than in cases of puerperal metro-peritonitis, provided operation can be performed early. Outside of these there is but little to hope from laparotomy, because the peritonitis is merely a local manifestation of a general systemic infection.

As it cannot be known in advance with which class one has to deal, it is justifiable to open the abdomen in every case of acute puerperal peritonitis, if it can be done early, and thus save some lives. Late operations are certain to be followed by the loss of the patient.

Dr. Skene agreed with Dr. Maury that laparotomy was undoubtedly the best treatment when there was localized pelvic inflammation and pus-accumulation, as the results have shown, but in general post-partum peritonitis he would expect the results of laparotomy to be unsatisfactory.

Dr. Gill Wylie, of New York, was convinced that cases of puerperal fever were simply septic, and, if treated in the beginning, were almost all curable by washing out the uterus and draining. He had cured

seven cases out of nine, seen early, in Bellevue, by this method. The great trouble was in getting permission to operate early; most of the cases are not seen by the laparotomist until they are hopeless.

DR. GARRIGUES, of New York, believed that over one-half of even bad cases of puerperal fever, if seen early, recover by medical treatment.

DR. ANDREW F. CURRIER, of New York, read a paper entitled "A Study Relative to the Functions of the Reproductive Apparatus in American Indian Women," which appears elsewhere in the current number of THE MEDICAL NEWS.

THIRD DAY—SEPTEMBER 24TH.

DR. J. C. REEVE, of Dayton, read a paper entitled, "The Treatment of Extra-uterine Pregnancy," by PROF. F. WINCKEL, of Munich, which recommended injection of morphine into the amniotic sac.

There is no question that the inflammation of the pelvic organs attending extra-uterine pregnancy may naturally enough continue after the death of the fetus, and may be the cause of many complaints, but that the presence of the dead fetus is the cause of these symptoms cannot be regarded as proved.

Dr. Winckel related a case of ten months' tubal pregnancy, in which laparotomy was performed, the child and placenta extracted, the tubal sac mopped out with iodoform gauze, and closed by sutures. The patient was perfectly well when discharged, and shortly afterward menstruation reappeared. In such a case laparotomy is the only rational treatment. The necessity of laparotomy in certain cases of extra-uterine pregnancy was demonstrated by Dr. Winckel twenty-seven years ago, when he performed his first laparotomy, but his experience has taught him that it is not necessary to operate in the first few months of extra-uterine pregnancy, but that it is easier and better to treat such cases by injection of morphine into the amniotic sac. The woman is not mutilated, both ovaries and tubes remain, and there is a possibility of the tube that was impregnated resuming its functions.

If, after the death of the fetus by morphine, the patient complains of great physical suffering, then laparotomy is still possible, while the operation then is less dangerous.

The injection of morphine into the amniotic sac can be made by any practising physician. The extirpation of the sac by laparotomy cannot be successfully performed except by a skilled operator.

DR. CORNELIUS KOLLOCK, of Cheraw, S. C., read a paper on "The Immediate Closure of Laceration of the Cervix," in which he did not maintain that laceration of the cervix should always be closed immediately after labor, but that there are many instances in which such closure is not only proper but urgent. When the conditions are favorable, and the operation can be performed without too much handling of the congested and torn cervix, the sooner the cervix is closed the better—not only for the instant relief afforded, but also for the promise of more certain and complete union of the parts; the woman is also saved much mental and physical suffering. In some respects the primary operation for laceration of the cervix stands to the secondary operation as the primary operation for laceration of the perineum stands to the secondary operation. In both primary operations fresh parts are brought together, and healthy union is sure to take place. The knife is not used in either case, and shock and hemorrhage from that source are avoided.

It has been claimed that sutures introduced for the immediate closure of a laceration of the cervix cannot be depended upon, because as the congestion and tenderness of the cervix subside the sutures will become loose, and fail to keep the edges of the laceration in proper coaptation. In answer to this it may be said that it is not at all uncommon for sutures to pull out when the secondary operation for laceration of the cervix is performed. The objection to the secondary operation is that the presence of cicatricial tissue renders the parts more difficult of coaptation and the process of union slower. The congestion and tender condition of the cervix does not forbid the introduction of sutures into it. In the Cæsarean section, which is now performed with signal success compared with what it was twenty-five years ago, sutures are introduced into the uterus when it is in the highest state of congestion, and when its vascularity is very great, and the tendency of the sutures to pull out is not reckoned among the most potent causes of the failure of the operation.

DR. CHARLES JEWETT remarked that he had performed primary closure of the cervix in a few instances, with entire satisfaction. It is a proper procedure when the cervix is torn to any extent, and imperative when the cervix is deeply torn. The operation may be objectionable in ordinary hands, but presents no difficulties for the expert. There was danger of infecting the patient; much manipulation of the birth-canal after labor should be avoided. If the birth-canal were thoroughly aseptic many of the minor lacerations would heal spontaneously.

DR. EMMET, of New York, would not undertake to immediately repair a lacerated perineum unless there was hemorrhage. If, by keeping the cervix clean, the patient is protected against blood-poisoning, local peritonitis, or cellulitis, a laceration will repair itself. If it be deep or extensive, he would repair it, if possible.

DR. COE, of New York, regarded the measure as a purely hemostatic one. He regarded a laceration of the cervix as a contused wound, which should be allowed to heal by granulation.

DR. A. P. DUDLEY, of New York, was in favor of the primary operation, because it secured immediate union and obviated the necessity of cutting away any portion of the uterus to get union by the secondary operation, thus also avoiding the deformity resulting from the use of the knife.

DR. KOLLOCK, in closing the discussion, remarked that, without regard to the occurrence of hemorrhage, if the laceration was extensive, he would advocate its immediate closure.

DR. EUGENE GEHRUNG, of St. Louis, read a paper entitled, "The Preventive and Conservative Treatment of Pelvic Tumors," in which he maintained that when in case of a pelvic tumor, other than surgical means of treatment are applicable, though the result be less brilliant, the simpler means should have the preference. In conformity with a universal law, the greater the resistance to the growth of a pelvic tumor the more rapid and destructive is that growth; in the absence of

resistance, growth may cease and retrograde changes follow. Many small myomata that may have existed in the pelvis for years, suddenly display great activity of growth when compressed and irritated; the circulation being interfered with, congestion follows and growth is rapid. Many sub-peritoneal tumors commence to grow rapidly only after they begin to sink into the small pelvis, where the resistance is greatest. The ovary is subject to the same law, the commencement of its abnormal growth frequently dating from its displacement or strangulation by adhesions. If displaced, it is compressed by surrounding organs, and pathological processes follow, with the development of cysts.

The same is true of the uterus, which becomes enlarged if by displacement its venous circulation is interfered with, or atrophied if its arterial circulation is impeded. It may be stated as a general rule that an incarcerated myoma or other tumor, a displaced ovary, or a strangulated womb, will, upon being released from its precarious position, cease to grow, and if kept free from pressure will in time return to its normal size.

As preventive measures and as a means of obtaining these results, Dr. Gehrung recommended: 1. A clear and early diagnosis of the tumor. 2. The hands of the operator, by means of which possible adhesions may be broken up and the tumor lifted out of the bony pelvis. 3. The almost lost art of the scientific use of the pessary —the tumor or organ, being freed from its imprisonment, should be supported in the correct position by a pessary. Tampons of cotton or other material may be used as a temporary means, but, as a rule, they are inefficient.

Dr. Edward Reynolds, of Boston, read a paper on "The Anatomical Relations of the Lacerated Perineum to the Mechanics of its Causation," detailing observations made during the last five years upon the shape and position of rents in different cases, with a classification of all perineal and vaginal tears as modifications of one type which is substantially that described by Dr. Emmet, in 1883, consisting of two lateral longitudinal tears of the vagina, joined at their lower extremities by a transverse tear and connected with the external surface by a median tear of the tissues below the crescent. This tear, but slightly modified, is stated to be the most common form. The next in frequency is one of the lateral tears, half the crescent, and the external tear. The crescent alone is not infrequent. One lateral tear sometimes extends down through the skin by the side of the anus, without passing toward the median line. All lesser variations could be arranged under these four varieties. The determination of the rent depends upon the anatomy of the pelvis. The tissues of the pelvic floor may be divided into layers, of which the superior consists of the recto-vesical and obturator-vesical fascia, with the coccygeal muscles, reinforced anteriorly by the triangular ligament; while the inferior layer consists of the two layers of the superficial fascia, compressor urethræ, superficial, transverse, and sphincter ani muscles.

The essential element in the repair of all lacerations must consist in the introduction of such sutures as will draw the torn edge of the upper layer of muscles downward, and that of the lower layer upward until both meet at the central point where they were originally separated.

Dr. George Keith, of Brooklyn, read a paper on "The Electrical Treatment of Uterine Fibroids in England," in which he stated that a careful study of the work of surgeons in Great Britain for some years past and a comparison of the results obtained by the electrical treatment for the cure of uterine fibroids with those obtained by hysterectomy and removal of the ovaries, confirmed his belief in favor of the electrical treatment. The treatment of fibroids of the uterus should not be restricted to any one method. It is held by some that electricity will cure the vast majority of cases, and obviate the necessity of hysterectomy in many. Hysterectomy is no doubt often performed for the removal of a tumor giving little trouble, which could have been cured by electricity.

Hysterectomy has in its favor, when the patient does not die after the operation, that the tumor is done with for all time and the convalescence is rapid. The disadvantages are: the mortality; the melancholic condition into which patients frequently fall; the fact that the life of the ordinary fibroid is limited.

Electricity is in its infancy. When it is as old as hysterectomy the death-rate will have been much diminished. There are some cases in which operation is to be recommended. This must be insisted upon, for the opponents of electricity are apt to say that its advocates decline operative procedures on all occasions. Hysterectomy is advisable in large fibro-cystic tumors, and also perhaps in those surrounded by free fluid; also for removal of the appendages when the tubes and ovaries are seriously diseased, especially if there be any suppuration.

Dr. W. E. Ford stated that he had investigated a number of the cases treated by him in the past seven years, and found that a large number of the small fibroids were cured, and the very large intra-mural growths lessened in size. In dangerous cases of large fibroids, galvanism promises more than hysterectomy. These large fibroids are adherent and make dangerous cases for operation, but they are safe for electricity, provided there is no history of pus-accumulation in the pelvis. The element of cure in the galvanic current is its ampèrage and not its voltage—the volume and not the tension produces the electrolysis.

Dr. Sutton was strongly opposed to electricity in these cases, and believed that hysterectomy was the only rational procedure.

Dr. W. H. Baker, of Boston, said that electricity for the treatment of fibroids had been a success in his hands, and he was satisfied with the results in nineteen cases out of twenty.

Dr. Clement Cleveland, of New York, read a short paper, entitled "Laparotomy in Trendelenburg's Posture, with Exhibition of a New Operating-table." In the posture recommended by Trendelenburg the body is so placed that the intestines will fall toward the diaphragm and at the same time leave the abdominal muscles relaxed. The body, with the head, is inclined downward, the weight of the body resting on the shoulders, the thighs and knees flexed on the body, so as to secure relaxation of the abdominal muscles. A saving in time of at least fifty per cent. is gained by the use of this posture in preference to the ordinary laparotomy position.

The table exhibited was available for the Trendelenburg posture, or for general gynecological work. When used for the latter purpose, it was brought to a horizontal position and firmly clamped, and would sustain a weight of 200 pounds.

DR. HENRY D. FRY, of Washington, read a paper on "Diabetes Mellitus Gravidarum," which will shortly appear in THE MEDICAL NEWS.

The following officers were elected for the ensuing year:

President.—Dr. John Byrne, of Brooklyn.

Vice-Presidents.—Dr. R. B. Maury, of Memphis, and Dr. Cornelius Kollock, of Cheraw, S. C.

Secretary.—Dr. Henry C. Coe, of New York.

Treasurer.—Dr. Matthew D. Mann, of Buffalo.

Council.—Dr. J. W. Chadwick, of Boston; Dr. H. T. Hanks, of New York; Dr. S. C. Gordon, of Portland, Me.; Dr. J. E. Janvrin, of New York.

The following new Fellows were elected:

Dr. Geo. M. Tuttle, of New York; Dr. William E. Mosely, of Baltimore; Dr. Florian Krug, of New York; Dr. Geo. Edebohls, of New York; Dr. Chas. P. Noble, of Philadelphia; Dr. Edward P. Davis, of Philadelphia; Dr. Virgil Hardon, of Atlanta; Dr. Charles Strong, of Boston; Dr. B. C. Hirst, of Philadelphia; Dr. A. McLaren, of St. Paul; Dr. F. H. Martin, of Chicago; Dr. P. H. Ingalls, of Hartford. Honorary Members: Dr. Samuel Pozzi, of Paris; Professor Olhausen, of Berlin; Professor Leopold, of Dresden.

The meeting then adjourned, to meet in Brooklyn on the third Tuesday in September, 1892.

AMERICAN CLIMATOLOGICAL ASSOCIATION.

Eighth Annual Meeting, held at Washington, September 22, 23, 24, and 25, 1891.

FIRST DAY—SEPTEMBER 22D.

DR. FREDERICK I. KNIGHT, of Boston, delivered the President's Address. He emphasized the importance of retaining the one hundred millions of dollars annually spent by Americans at European health-resorts, by a more intelligent exposition of the equal value of American mineral waters and climatic conditions. He recommended annual meetings of the Climatological Association to be held at health-resorts, with the double object of acquiring personal familiarity with the value and character of our own resources, and for the stimulation of those concerned in efforts in the line of improvement. Resorts for tuberculous patients should be tabulated, and rooms should not be indiscriminately occupied by the sick and the well. After having been occupied by tuberculous patients, rooms should be disinfected under medical supervision.

DR. BEVERLEY ROBINSON, of New York, read "Notes on General *versus* Local Treatment of Catarrhal Inflammations of the Upper Air-tract." Nasal obstructions *per se* do not require treatment, but if a source of disease, the lining membrane should be removed. In cases of traumatism sprays should be used. The nasal douche is a two-edged sword. Vaselin, cosmolin and albolin are beneficial. A torpid liver bears some relation to nasal catarrh. Chronic gastric catarrh is also related to some cases of hypertrophy of the nasal mucous membrane. Treatment with the cautery, properly applied, is innocuous. When a deviated septum is productive of disease, it should be operated upon. Nasal obstruction is not so frequent a cause of disease of the tonsils, eyes, and ears as is generally supposed. Rheumatism and gout are often associated with disease of the upper air-tract. The cough of so-called hysteria, anemia, etc., is often due to enlargement of the lingual tonsil, giving rise to irritation of the epiglottis. Lithemic conditions may act as a cause of enlarged lingual tonsils. The globus hystericus is often due to an enlarged lingual tonsil.

DR. E. O. OTIS, of Boston, read a paper on "Gymnastic Exercise as a Prophylactic and Remedy in Chest Diseases." He stated that from his experience as the medical director of a city gymnasium, making many physical examinations of men and boys, and prescribing systematic gymnastic exercises for them, he is convinced that gymnastic exercise, scientifically carried out, constitutes a prophylactic agent of great value in diseases of the chest, and a valuable aid in the maintenance of sound and vigorous hearts and lungs in the trying conditions of in-door city life. He also believes that gymnastic exercise can be extended to actual diseases of the chest, and is a therapeutic measure of no mean value. Two conditions frequently encountered suggest future disease, particularly in men between the ages of thirty and fifty: First, a certain lack of vigor and firmness in the action of the heart—"sedentary" heart—often accompanied with overweight and shortness of breath; second, poor and incomplete expansion of the lungs, with diaphragmatic breathing and disuse of the intercostals.

A patient belonging to the "sedentary" heart class is put upon light, slow work at first, rapid walking or slow running, chest-weights, gentle rowing and free-hand exercise, etc. If a case of poor lung-expansion, he is put upon lung-expanding apparatus of various kinds, rowing, free-hand work, or class work, with wooden dumbbells, etc. Swimming is one of the best forms of exercise for expanding the lungs. Over-development of the chest muscles is often detrimental to good lung expansion. The gymnastic remedy described for vicious habits in non-diseased lungs may, under careful supervision, be applicable to actually-diseased conditions in their inception. To promote proper and greater chest-expansion and more complete extension of the lungs is on the lines of the high-altitude climatic cure, which excites more rapid and fuller respirations. Many patients do not know how to breathe properly, and often the intercostals are so weak they cannot do their share of the work. Proper gymnastic exercise carefully watched is of much avail in training the patient how to breathe properly. Consumptives are sometimes advised, or on their own responsibility attempt physical exercise in an irregular way, using chest-weights at home, and the like. This is of questionable utility, if not absolutely injurious. The exercise must be carefully adapted to the special case and constantly supervised.

The cardiac diseases most appropriate for the exercise-treatment are fatty heart and well-compensated cardiac disease. The objection to mountain climbing is its difficulty of regulation. The therapeutic efficacy of moderate and carefully-regulated and supervised gymnastic exercise is generally admitted.

DR. VAN BIBBER, of Baltimore, read a paper on "The

Climate of the Greater Piedmont and the Mountainous Region of the South."

SECOND DAY—SEPTEMBER 23D.

DR. E. L. SHURLY, of Detroit, read an exhaustive paper upon "A Study of the Sputum in Pulmonary Consumption," in which he dwelt largely upon the results obtained by injecting into mice solutions of phthisical sputum containing various chemical agents.

In a paper entitled "The Surgical Treatment of Acute and Chronic Empyema," based upon an experience of considerable magnitude, DR. MAURICE H. RICHARDSON, of Boston, expressed the view that all methods of treatment of empyema other than the surgical were objectionable and unscientific. He considers immediate drainage imperative. Thorough asepsis must be enforced for at least twenty-four hours before the operation, the patient's body and surroundings being placed in the most aseptic condition possible. The incision should be made directly over a rib, preferably the seventh or eighth, and should be from two to three inches long. The rib being exposed, one or more inches should be excised. A drainage-tube not less than three-eighths of an inch in diameter should be placed alongside of another of the same size, and the two introduced into the wound. For the sake of cleanliness, several sets of these tubes should be prepared. If the opening in the chest-wall is sufficiently large, Dr. Richardson regards washing out of the cavity as of doubtful efficacy. If any solution is used for this purpose, it should be the sodium chlorate, 1 : 10, which is of special service when an offensive odor emanates from the purulent collection. Carbolic acid solutions are dangerous. The family history is the most important element in the prognosis of acute empyema treated surgically. If phthisis is hereditary the lung will probably not readily expand.

DR. F. H. BOSWORTH, of New York, read a paper on the subject of "Lymphatism," a name that he would restrict to that constitutional condition under the influence of which the lymphatic glands in the neighborhood of the faucial ring become the seat of hypertrophic changes, excluding from the definition those graver change in the lymphatic glands that constitute Hodgkin's disease and like affections, as well as those extensive lymphatic enlargements in the neck that tend to undergo suppurative changes. Manifestations of lymphatism are enlarged faucial tonsils, adenoid disease in the vault of the pharynx, and hypertrophy of the lingual tonsil.

Dr. Bosworth emphasized the fact that the existence of the enlarged lymphatics in these various regions should be accepted as evidence of a constitutional taint, rather than as constituting simple obstructing hypertrophies in the throat. He furthermore insisted that, especially in the earlier years of life, before these masses have become fully and firmly organized, they were amenable to internal treatment, preference being given to the iodide of iron. He argued that this drug was almost a specific in controlling these growths, but that the mistake usually made was in giving it in too small doses. For a child five years old the dose should be at least two and a half grains given three times daily, or half a teaspoonful of the officinal syrup. Its effects should be watched carefully, and the dose increased to five grains, or even more. This not only reduces the lymphatic hypertrophies, but also corrects the anemia that so commonly attends the disease.

After the affection has lasted a few years, of course, the hypertrophies become so thoroughly organized that no internal medication serves to reduce them. In these cases, the masses should be treated in precisely the same manner as other tumors, and subjected to surgical measures; but even in the older cases the constitutional treatment of the lymphatism, which causes the local disease, should not be neglected.

DR. JACOBI, of New York, stated that he does not regard lymphatism as a disease *per se*, but as the result of some local irritation of the head, ear or mouth. Eczema, common nasal catarrh or post-nasal catarrh, untreated, will give rise to a chronic adenitis involving the glands of the neck and extending to the mediastinal and axillary glands. He urges the importance of prophylaxis in the treatment of the condition.

"The Histological Changes that Take Place in the Lungs in Cured Phthisis, and the Influence of Diathesis in the Development of Such Changes" was the title of the paper read by DR. ALFRED L. LOOMIS, of New York. He dwelt upon the development of fibrous tissue in all cases of phthisis that terminate in recovery. In some of the cases a pleuritic fibrosis seems to be the first change. A condition of intense hyperemia is always present in phthisis, and this tends to the formation of fibrous tissue. The antagonistic action of the diathesis is revealed in many of these cases of cured phthisis. Individuals with the fibroid diathesis enjoy a relative immunity from phthisis, and, when the disease does develop, resist its action in a remarkable degree. Dr. Loomis quoted ten cases illustrative of the inhibitory influence of the gouty diathesis upon the progress of phthisis. If Koch's tuberculin be of any value in the treatment of phthisis he believes that it is because it excites around the diseased foci an inflammation that tends to the production of fibrous tissue.

DR. JACOBI stated that he regards phosphorus and arsenic as the two principal remedies that favor the production of fibrous tissue. He has used phosphorus for twenty years in chronic osteitis and incipient Pott's disease of traumatic origin for the purpose of producing a new formation of fibrous tissue in bone. He also uses arsenic in lung troubles for the same purpose.

DR. CURTIN, of Philadelphia, ascribes the curative results of the injection of iodine into tuberculous cavities to the inflammatory new-formation of fibrous tissue that follows.

DR. BEVERLEY ROBINSON, of New York, expressed the view that injections of iodine into the inflamed tissue around the cavity would be more beneficial than injections into the cavity itself.

DR. S. A. FISK, of Denver, read a paper on "Some Further Considerations of the Analysis of Recorded Cases of Phthisis Pulmonalis." He claims that improvement may be expected in two out of three cases; that men do better than women; that those over twenty have a better chance than those under twenty years of age; that heredity should be no drawback to living in Colorado, and that the hemorrhagic tendency should not debar the patient from coming. The ratio of cures is 32 per cent.

DR. H. F. WILLIAMS, of Brooklyn, in "Some Reflections on the Attempts that have been Made to Discover Specifics for Phthisis," called attention to the good results that have attended the employment of the pneumatic cabinet devised by him.

DR. FRANK FREMONT SMITH, of St. Augustine, in speaking of "The Value of Koch's Remedy Employed as an Alterative: Reactive Fever Prevented," claimed that the dose of tuberculin can only be determined by the effect upon the patient. He believes that all stages of phthisis can be treated without reactive fever and without danger by regulating the dose employed. Weak men and nearly all women improve very slowly under its use.

THIRD DAY—SEPTEMBER 24TH.

A paper on "The Epidemiology of La Grippe and Its Relations to Catarrhal Fever," by DR. ROLAND G. CURTIN and DR. E. W. WATSON, of Philadelphia, was read. It was related that catarrh of the bladder and kidneys was characteristic of the disease. The same organ or tissue is never affected in a second attack. This was especially true of the lung. The rapid dissemination of influenza was ascribed to the universal prevalence of a warm and moist atmosphere. Its progress in some respects simulated that of cholera and of dengue. From the history of previous epidemics, it was thought probable that the coming winter would witness an outbreak of the disease, with new manifestations involving the throat, and resembling diphtheria. Dr. Curtin occasionally observed an eruption, occurring in crops upon the abdomen and resembling the rose-spots of typhoid fever. Meningeal involvement and heart-failure were the most frequent causes of death.

DR. JOHN C. MONRO, of Boston, placed the average period of incubation at four days, and the duration of the acute symptoms at from three to six days. Complete recovery did not follow for months. The disease was most prevalent between the ages of fifteen and fifty. In the working-classes, men were most often affected and the disease was most serious among them, while among the better classes women were the most frequent sufferers. Headache was the most common symptom. During the prevalence of the epidemic lung troubles were greatly increased, and the mortality was large.

DR. A. A. SMITH, of New York, stated that in a large number of cases he had observed an eruption closely resembling that of scarlet fever, which disappeared in two or three days without desquamation. This occurred in adults with but one exception, and that in a half-grown child. Urticaria was frequently observed, especially in cases in which the gastric system was disturbed. In two instances the eruption resembled that of measles. Purpura was present in many cases, occurring late in the attack or during convalescence. Petechiæ appeared on the extremities, and in a few instances remained for a few weeks, disappearing slowly. In many cases there was great mental depression; acute mania was present in a few. A suicidal tendency was frequently observed; a homicidal tendency rarely. Seven cases of marked jaundice were observed.

DR. CURTIN expressed his belief in the contagiousness of the disease. The crowding of the sick in small compartments intensified the attack. Croupous pneumonia was rare, but the catarrhal form occurred frequently among the working-people. Pericardial distress was noted in many cases, but inflammation of the heart was rare. The heart's action was commonly irregular, slow and feeble. In the early stages of the epidemic, heart-failure caused the largest number of deaths. Hemorrhages were not infrequent and, as a rule, occurred early. Dermatitis was very common, five cases coming under observation in one day.

DR. R. J. NUNN, of Savannah, stated that he treated the disease as a neurosis, involving the central nervous system. His treatment was stimulating; ammonia, nux vomica, and hydrastis were found to be of most service. Opium appeared to act badly in all cases; in many instances change of climate was essential.

DR. E. FLETCHER INGALS, of Chicago, observed that children were much less frequently attacked than were adults. Inflammation of the cornea was frequently noticed. It occurred in two types; in the first, zigzag lines of ulceration were present upon the cornea, while in the other the surface remained bright and unbroken. Inflammation of the middle ear, slight or severe, occasionally occurred. A tendency to the development of inflammation of the pleura was marked in the last epidemic, while cerebro-spinal meningitis was common in 1890. Tracheitis was a frequent complication; pleuro-pneumonia was exceedingly common and disastrous in its results.

DR. J. C. MULHALL, of St. Louis, noticed that the disease showed no regard for social position, and that the weak and strong were alike attacked. Pulmonary phthisis was the most common sequel. He believes that the *materies morbi* of la grippe often awakens dormant or healing pathological processes. One peculiar manifestation was a loss of the whole or part of the upper register in soprano voices. One attack of the disease did not protect from subsequent attacks. Vaso-motor paralysis was frequent. In all of the cases phenic acid acted well.

DR. LEVICK, of Philadelphia, drew a comparison between the epidemic of 1861 and the recent epidemic. He has long believed that a close relationship exists between epidemic catarrhal fever and epidemic cerebro-spinal meningitis. He believes that should the coming winter be cold, we shall have an epidemic of cerebro-spinal fever.

DR. J. H. MUSSER, of Philadelphia, agreed with Dr. Curtin as to the contagiousness of the disease. He recommends prompt measures of prevention.

DR. S. A. FISK, of Denver, observed that the influence of the disease upon the nervous system was decided. Consumptives appeared to be entirely exempt from the disease.

DR. A. H. SMITH has used largely phenacetin in the treatment of the disease, combined with camphor and atropine, to prevent the profuse perspiration. He believes the disease to be zymotic in orgin.

DR. CURTIN called attention to the frequency with which angina pectoris followed attacks of la grippe. During the past two years he has seen more cases of angina pectoris than ever before. He also advocated the use of oil of sandalwood, taken upon a lump of

sugar, for the allevitaion of the cough, provided the stomach would bear the administration of that remedy.

Fourth Day—September 25th.

Dr. W. A. Jayne, of Georgetown, Colorado, read a paper entitled "An Experience with Diphtheria at a High Altitude." He reviewed sixty-eight cases of diphtheria observed in the Rocky Mountains, at an elevation of 8500 feet above sea-level. The outbreak was attributed to unsanitary local conditions. The death-rate approached that of the milder rather than of the more severe epidemics. The fatal cases were mostly those in which extension to the nasal cavities occurred, the fatal issue being dependent upon septic influences. Such extension occurred in nearly one-half of the cases, commencing in the pharynx; it could not be ascribed to antecedent catarrh, but rather to those general causes that determine varying degrees of virulence. Grave forms are encountered when the environment is particularly bad. In the cases in which recovery took place there was a remarkable absence of all sequelæ, and convalescence was prompt and satisfactory. The type and severity of diphtheria varies greatly even under apparently similar conditions, from causes as yet not understood. Climate has little to do with these variations, but the degree of dampness of air and soil probably has some influence. Humidity is essential to germ-life, dryness inimical to it. The climate of dry, high altitudes has a restraining influence on the development of the tubercle bacillus and of pyogenic bacteria, probably also upon the diphtheria bacillus.

It has been asserted that the virulence of diphtheria is increased by the atmospheric rarity and the low temperature of high altitudes. No basis for such an assumption can be found in theory or in comparative observations at the bedside. Given similar local conditions, diphtheria will probably be found more quickly to develop and assume greater virulence in the more humid atmosphere of a low elevation than in the drier air common to most high altitudes, and that the degree of elevation *per se* is not a determining factor.

Dr. Rogers, of Denver, noticed that in the majority of severe cases the nose was invariably involved; he therefore advised early treatment of the nares. Moisture favors the spread of the disease, and is most common in Colorado as the snow melts after a storm. In the treatment of the disease he recommends the free use of mercurials. He prefers a solution of the bichloride, one grain to the ounce, together with a strong solution of the tincture of iodine and hydrogen dioxide. To a child of five he gives gr. $\frac{1}{48}$ of the bichloride every two hours. To older children he has given gr. $\frac{1}{12}$ every two hours for forty-eight hours. The only limit to the dose is the effect upon the membrane. He always uses iron in combination with mercury. Since using the large doses of mercury he sees fewer deaths from nephritis.

Dr. W. C. Glasgow, of St. Louis, has lost twelve cases of diphtheria during the year, and he ascribes the result to the use of mercury. He has used hydrogen dioxide extensively and considers it of great value, especially when membranes form in the larynx.

Dr. C. C. Ransom, of Richfield Springs, N. Y., read an interesting paper upon "The Waters of Richfield Springs," in which he gave a description of the springs, with the methods of using the waters. The bathing establishment is elaborately equipped with accommodations for Russian and Turkish baths and facilities for medicated baths. There are inhalation-rooms in which the sulphurous water is atomized and applied directly to the affected part, while gymnasia, completely equipped with apparatus for men and women, provide excellent opportunities for muscular development. The waters are rich in sulphuretted hydrogen, and to this is due their efficacy. The water is drunk before dinner, and the patient should walk at least for a half-hour after drinking, in order to favor its absorption. The immersion-bath or tub-bath is the favorite method of external application. The duration of the bath is from six to twelve minutes; the immediate effect is depressing, the depression lasting from half an hour to three hours. In conjunction with the bath, massage is employed with good results in the treatment of insomnia. The spinal douche is applied just before retiring. No treatment for rheumatism and gout gives such good results as the use of the waters of Richfield. Sciatica is improved. Two cases of catarrhal jaundice were cured by a strong douche directed upon the hepatic region. The strictest care is required in the treatment of the general condition of all the patients, who are put upon an almost absolute meat diet, to the exclusion of fresh fruits, starches, and sweets.

Dr. Carl Kuedi, of Denver, called attention to the difference between the methods of dieting at Richfield and in Europe. At the Continental resorts a liberal meat diet is forbidden.

Dr. Geddings, of Aiken, S. C., read a paper upon "The Simultaneous Occurrence of Three Cases of Lepra in One Family, Following Immersion in Filthy Salt-water, in a Flooded Cellar." The disease commenced as bullæ upon the left leg, which gradually developed into white cicatrices with marked anesthesia. The etiology was uncertain.

Dr. W. W. Johnston, of Washington, read an abstract of his paper upon "The Effects of Climate in the Treatment of Chronic Diarrhea," in which he divides all cases of diarrhea into two classes: the primary form embraces cases with or without ulceration, the type of which is the chronic diarrhea of the army; the second is that occasioned by overwork in men and frequent child-bearing in women. Prolonged rest in a suitable climate is essential to successful treatment. A warm, equable climate is not as useful as a dry, cooler climate.

Dr. J. H. Tyndale, of New York, read a paper upon "The Pre-tuberculous Condition," which will appear in full in a subsequent number of The Medical News.

Dr. Carl Kuedi, of Denver, read a paper upon "The Treatment of Sixty Cases with Tuberculin at Davos." He has observed that females require larger doses of tuberculin than males to produce the same effect. He regards the local reaction as the most common and most important of the effects of tuberculin.

Dr. Karl von Ruck, of Asheville, claims that he preceded Dr. Smith, of St. Augustine, by five weeks in the administration of tuberculin without reactive fever. He believes tuberculin has a great future before it.

The Association adjourned, to convene next year at Richfield Springs, New York.

ASSOCIATION OF AMERICAN PHYSICIANS.

Sixth Annual Meeting, held at Washington, September 22, 23, 24, and 25, 1891.

(Continued from page 375.)

FOURTH DAY—SEPTEMBER 25TH.

DR. JOHN S. BILLINGS, Surgeon in the United States Army, of Washington, read a paper on "The Condition and Prospects of the Library of the Surgeon-General's Office and its Index-Catalogue," which appeared in full in THE MEDICAL NEWS of September 26th.

DR. D. W. PRENTISS, of Washington, then read a paper, entitled, "Sequel to a Case of Slow Pulse (Purdy)." The case reported had already twice been presented to the Society. The slow pulse had continued for more than two years, varying from 11 to 40 per minute. During a short period of this time the frequency was normal, but it soon again fell within the limits mentioned. The man was a subject of frequent attacks of syncope, which were most frequent when the pulse was slowest. No disease of the heart or other organs could be detected. Flint has called this condition "functional slow pulse."

In looking over medical literature, Dr. Prentiss has found records of ninety-three cases almost identical with that which he has reported.

Continuing, Dr. Prentiss reported that from May 24th until the time of death the attacks of dizziness and fainting increased in frequency, the pulse ranging between 13 and 34 per minute. On July 2d the pulse was 15; the patient was restless and delirious, and in constant fear of being killed. July 4th the delirium became worse; the man was so impressed with the idea that he was about to be killed that he rushed through the house screaming and crying. He was, however, induced to lie down, when he became quiet, and died soon after while alone in his room.

The report of the autopsy was made by DR. ROBERT T. EDES, of Washington.

The post-mortem examination was made seventeen hours after death; the expression was tranquil; the body well nourished; the blood everywhere dark and fluid. The heart was large and firm; its muscular substance firm, not fatty; the walls of both ventricles thickened, perhaps the right more than the left. The lungs were well dilated. There was no atheroma. The stomach was normal; the spleen normal; the kidneys congested. The brain, as well as the larger sympathetic ganglia, was normal; the medulla was congested. The right pneumogastric nerve seemed normal. At the point where the left curves beneath the arch of the aorta some of the strands seemed indistinct, and several fusiform enlargements were noted on these strands. At this point the nerve gives off several branches—one to form the esophageal plexus, others on the loop of the recurrent laryngeal just below the artery. At this point the recurrent laryngeal gave off branches to the cardiac plexus.

DR. PRENTISS then briefly reported two interesting cases from his own practice. The first was in a lady, twenty-five years of age, with light hair, suffering from contracted kidneys. She was given pilocarpine, gr. $\frac{1}{6}$, hypodermatically, two or three times weekly, for its diaphoretic effect. After two weeks it was noted that her hair had become chestnut-brown, and at the end of six weeks it was black. This occurred ten years ago, and the hair still remains black.

The second case was that of an old lady with gray hair, whose skin was so dry as to cause annoyance. For the relief of this condition the fluid extract of jaborandi was continuously given. At the expiration of six months her white eyebrows had become black; later, areas of the hair of the head began to turn black, and a growth of new black hair appeared. The woman soon after this rather suddenly died.

The President, DR. PEPPER, suggested the advisability of making some provision for the admission into the Society of men of high scientific rank in the departments of hygiene and bacteriology. He thought it better to have such men admitted to this Society than to have them form an independent society, as would inevitably happen, if they were not admitted. The membership of the Society is limited to one hundred, and there are at present but three vacancies, with many applicants waiting for admission.

A motion of DR. BUSEY, seconded by DR. BILLINGS, was carried to refer the matter to the Council to report an amendment.

DR. THEOBALD SMITH, of Washington, read a paper on the "Changes in the Red Blood-corpuscles in the Pernicious Anemia of Texas Cattle-fever," in which he said that in cover-glass preparations of blood from cases of progressive anemia in Texas cattle-fever, stained in alkaline methylene-blue and decolorized in acetic acid, certain peculiar conditions of the corpuscles may be noted. When the number has fallen slightly below three million, a small percentage appear with a variable number of stained particles disseminated uniformly through the corpuscle. In some cells these particles are relatively large, and might be mistaken for micrococci, if it were not for a certain variability in size. Each corpuscle may contain from three to twenty, or more, of these bodies. As the number of cells continues to fall, corpuscles appear that are beset with an increasing number of stained particles, diminishing in size until forms appear the discs of which seem covered with a precipitate of exceedingly minute stained points. Not all the particles with recognizable form are round—coccus-like, but some are angular and some appear like short rods. As a rule, the smallest particles are associated with the more advanced stages of anemia, although cells with granules of various sizes are found together. When the number of corpuscles has descended to between one and one-half and two millions, many of the large corpuscles are stained uniformly of a pronounced bluish-red. Such corpuscles are usually somewhat folded, owing to their thinness. The edges are not sharply defined, and within the disc is usually a paler circular or elongated spot. The stain is not resolved into points by high powers (+1500). Curiously enough, corpuscles containing stained granules have not been detected in preparations from the parenchyma of spleen, liver and kidneys, but are evidently confined to the circulating blood. Diffusely-stained cells are not so restricted, but may be observed in the organs as well. In the blood containing from one to two million corpuscles, nucleated red corpuscles or hematoblasts are present.

They increase in number as the whole number of corpuscles diminish. The hematoblasts are equally abundant in the circulating blood, in the spleen, the liver and the kidneys.

The order in which these different kinds of corpuscles appear in the circulation, as well as the particular stage during which each kind makes its appearance is not always as described, although the description given applies to the great majority of cases examined. In animals in which the destruction goes on rapidly, fully two-thirds of all corpuscles may have been destroyed before any of the modifications appear, and in most acute, fatal cases death ensues before they are observed at all. It is only in the more chronic, milder cases that these modifications are best studied. Their disappearance when recovery begins is in the inverse order of their appearance and goes on quite rapidly.

That these morphological variations are due to the anemia and not to any other cause may be demonstrated by practising venesection on healthy animals. The changes were called forth both in a cow and in a lamb by artificially reducing the number of red corpuscles by bloodletting.

It was held that the modified corpuscles are embryonic or transitional in character. Similar modifications seem to have been observed in human blood-corpuscles. Some regard them as undergoing a coagulation necrosis; others, as corpuscles the development of which had been asserted.

In the discussion, Dr. Welch, of Baltimore, said that many of the forms described by Dr. Smith occurred in human blood in different conditions. He had, however, been in the habit of considering them as distinct forms, rather than as transition states of the same corpuscles.

Dr. J. H. Musser, of Philadelphia, then read a paper on "Grave Forms of Purpura Hemorrhagica." In so-called idiopathic cases no cause can be discovered. Symptomatic purpura may be dependent upon anemia, cachexia, malignant disease, scurvy, rheumatism, etc. It has been maintained that purpura is identical with scurvy. Purpura presents some of the symptoms of a grave septic condition.

The paper included the report of five cases. The first was in a female, forty-eight years old, who had always been in good health, enjoyed good surroundings, had not had rheumatism, and was without a history of bleeding in the family. As the menopause approached, decided menorrhagia occurred, at first thought to be due to a uterine fibroid that had been discovered. Later, hematuria developed. The blood was always vomited, but never with food. Before each attack, the patient suffered from pain. Purpura developed and the patient died.

The second case was in a boy, who had excessive gastro-intestinal hemorrhage, and severe joint-symptoms. Purpura was also a well-marked symptom.

The third case was in a man, twenty-six years old, a mechanic, in apparent good health. He had had rheumatism in childhood. He complained of recurrent sore-throat. Subcutaneous, subconjunctival, and submucous hemorrhages developed. The pulse was 120; the temperature 103°. The purpuric spots were round, tender and variegated. There were rheumatic symptoms and mitral and aortic valvular murmurs. The fauces were congested, the uvula edematous and covered with a diphtheritic-like exudation, and food regurgitated through the nostrils. Sloughing followed. The convalescence was slow.

In the fourth case, in a male, there were also recurrent attacks of sore throat. A large hemorrhage occurred in the uvula. The patient had three relapses. The edema was extreme; gangrene of the skin of the penis and scrotum followed. Hemorrhage occurred under the skin, from the lungs, and at one time there was hematuria.

The fifth case was in a female, twenty-three years old, who was suddenly taken ill with extreme nausea, with vomiting first, of acid fluid, and later of bile. Abdominal pain and diarrhea followed, and purpura developed with subsidence of the gastro-intestinal symptoms. The joints became painful and severe headache came on. The urine was normal. Fever was present, the temperature at times reaching 105°. Examination of the blood gave negative information. The rheumatism and purpuric symptoms and the headache continued; violent conjunctivitis and iritis set in; the patient became delirious and then stuporose, and death took place in coma, six days after the first symptom. No autopsy was allowed. Dr. Musser considered the case one of rheumatic purpura, with hyperpyrexia.

Dr. Pepper, of Philadelphia, reported having recently seen two school children, aged respectively eleven and thirteen years, suffering from grave purpuric hemorrhages. In each, vision in the left eye was lost, as a result of retinal hemorrhage. In two other cases, in women, below middle age, purpura developed after rötheln. There was hyperpyrexia, followed by extensive petechia and subcutaneous hemorrhages. The fall of temperature was rapid and recovery complete.

Dr. Prentiss, of Washington, referred to a case of a boy who had suffered from purpura for a long time, with many severe exacerbations. He had hemorrhages under the skin, from the bowels and bladder. After two large hemorrhages under the skin of the abdomen, sloughing occurred. Arsenic had seemed to be the most useful remedy. The use of phosphorus was suggested. Under its influence, the intervals between the relapses gradually lengthened, and recovery was completely established.

Dr. I. E. Atkinson, of Baltimore, read a paper on "Bradycardia in Acute Articular Rheumatism," in which he stated that when the action of the heart was retarded in acute rheumatism, this is most apt to occur during convalescence from the fever and independently of cardiac complications. Rheumatic fever is one of the diseases in which a rapid action of the heart would be expected, especially during the period of pyrexia.

Dr. Atkinson reported the case of a male, colored, nineteen years old, healthy, who took a cold shower-bath, after which he developed acute rheumatism, precordial pain, and a to-and-fro friction sound at the left sternal border. Epistaxis also occurred. The area of cardiac percussion-dulness was not increased. During convalescence the pulse was usually below 57.

In another case, in a student, who was subject to rheumatism and had disease of the mitral valve, during convalescence, even before the temperature was normal the pulse-rate was from 32 to 40 per minute.

It was thought that the inflammation of the heart, stimulating the peripheral filaments of the pneumogastric might be a cause of bradycardia; perhaps, also, the rheumatic poisoning circulating in the blood. It cannot be ascribed to drugs as it occurs when these have been withheld.

DR. PEPPER, of Philadelphia, said that he had occasionally noted infrequency of the pulse after convalescence from acute diseases.

DR. BOWDITCH, of Boston, questioned whether reasoning by analogy with animals, the slowing of the heart could be ascribed to paralysis of the intrinsic accelerator center, or as suggested to stimulation of the pneumogastric.

DR. ORD, of London, said that he had also, at times, noted infrequency of the pulse after acute illnesses. He has long thought that the pneumogastric nerve played an important part in acute rheumatism.

The following officers were elected:

President.—Dr. Henry M. Lyman, of Chicago.

Vice-President.—Dr. George Ross, of Montreal.

Secretary.—Dr. Henry Hun, of Albany.

Treasurer.—Dr. W. W. Johnston, of Washington, D. C.

Recorder.—Dr. I. Minis Hays, of Philadelphia.

AMERICAN ASSOCIATION OF ANDROLOGY AND SYPHILOLOGY.

Fifth Annual Meeting, held at Washington, September 22, 23, 24, and 25, 1891.

(Continued from p. 378)

THIRD DAY—SEPTEMBER 24TH.

DR. W. K. OTIS, of New York, read a paper on "Hematuria," in which he carefully considered the diagnosis. If the anterior urethra is the source of hemorrhage, the blood will flow continuously; if the posterior urethra—the pars prostatica—the flow of blood will be intermittent; the urine itself will be clear; if the bladder is the source of hemorrhage, the blood is intimately intermixed with urine. Blood-clots in the urine—the long coagula resembling worms—indicate renal hemorrhage, as they represent casts of the ureters. If the coagula are short and broad, they come from the bladder. A low specific gravity of the urine indicates renal hemorrhage; a normal or high specific gravity, vesical hemorrhage. Ammoniacal fermentation of the urine is indicative of vesical hemorrhage. The presence in the urine of hyaline casts, or casts containing blood-corpuscles, points to renal hemorrhage; but if only vesical epithelium is found, the hemorrhage is from the bladder. If examination of the urine furnishes negative information, instrumental examination of the bladder and the resorption-test are usually conclusive. In making the instrumental test, the bladder should first be washed out; then, if the catheter is moved about, the bleeding will be renewed if the bladder is the source of hemorrhage. In making the resorption-test, a solution of iodide of potassium is injected into the bladder by means of a soft catheter. If iodide of potassium is brought into contact with a free surface capable of resorption, iodine can be demonstrated in the saliva after a short time—not longer than fifteen minutes. In hematuria this would signify that the hemorrhage is from the bladder. If the bleeding is not too profuse, the electrocystoscope enables one to make a positive diagnosis.

DR. TAYLOR, of New York, stated that in severe cases of urethritis a little blood might flow from the anterior portion of the urethra as a result of the contractions of the muscular fibers upon the mucous membrane.

DR. BRYSON, of St. Louis, stated that he has seen many cases of renal hemorrhage in which the specific gravity of the urine was high, and he considered it best not to lay too much stress on that point.

DR. WILLIAM T. BELFIELD, of Chicago, read a paper entitled "Clinical Notes on (*a*) Hypertrophy of the Prostatic Sphincter; (*b*) Relation of Rectal Distention to Arterial Depression," in which he stated that hypertrophy of the prostatic sphincter, occurring secondarily to vesical irritation from stone, etc., is a well-known condition, but occurring as an apparently independent affection, without discoverable antecedent morbid changes, it is less generally recognized. He related the histories of two patients, aged nineteen and twenty-seven respectively, upon whom he had operated within the past year, and discovered a hypertrophied condition of the prostatic sphincter. The question was propounded whether in these cases there may not have been an antecedent morbid condition in the bladder, and whether hypertrophy of the prostatic sphincter may not be a frequent cause of vesical irritability.

At a previous meeting of the Association, Dr. Belfield had reported that in dogs irritation of the mucous membrane of the rectum caused a decided depression of arterial tension, amounting sometimes to 50 per cent. Since that time he has noticed that in a supra-pubic cystotomy or other operation in which the rectal bag was employed, there was marked arterial depression, which disappeared when the bag was withdrawn.

DR. WILLIAM N. WISHARD, of Indianapolis, read a paper entitled "Notes on the Surgery of the Prostate," in which he stated that the surgery of the bladder, particularly in recent years, suggests the following principles: 1. A large percentage of cases of prostatic cystitis, not susceptible of relief by palliative treatment, can be more or less permanently relieved by surgical interference. 2. Perineal and supra-pubic incisions are best calculated to accomplish the desired results. 3. Neither of these operations is suitable in all cases; both may sometimes be required. 4. The objects of a radical operation should be the removal of the mechanical obstruction to urination, and to secure rest and drainage for the bladder. Dr. Wishard stated that it must be borne in mind that at the time when many cases of disease of the prostate apply for treatment, the mechanical obstruction is by no means the most serious condition present. Resultant renal disease, loss of muscular power and thickening and diminution in the size of the bladder render more or less futile both palliative and radical efforts at relief.

DR. J. BLAKE WHITE, of New York, stated that a short time ago a patient came under his care who manifested very distressing symptoms of vesical irritability, frequent and painful micturition, etc.; the bladder and right ureter were made out to be dilated. Supra-pubic cystotomy was performed, and the prostatic sphincter

was found to be retracted. The sphincter was dilated with the finger, drainage was kept up for fifteen days, and the patient made a satisfactory recovery.

Dr. John P. Bryson, of St. Louis, stated that he did not consider as mechanical the failure of the heart that attends operations about the bladder, but as a general nervous disturbance, perhaps allied in some way to urinary fever, and which must be guarded against by the surgeon.

Dr. W. K. Otis, of New York, stated that he has reported a case in which a tumor of the prostate, about the size of the end of a man's thumb, was removed, and eight ounces of residual urine withdrawn. Eighteen months after the operation, the patient was still perfectly well.

Dr. Arthur T. Cabot, of Boston, read a paper entitled "Observations upon the Surgery of the Ureter," in which he reported the results of some investigations upon the anatomy of the ureter, with reference to its surgical accessibility in different parts of its course, and with the especial object of determining how best to reach and remove impacted stones in the ureter. When possible, it is always best to use the extra-peritoneal incision for the removal of a stone. The search for the ureter is greatly simplified by a knowledge of the fact—not mentioned in the usual descriptions of the anatomy of the ureter—that it is in relation with that part of the peritoneum that becomes adherent to the spine. After the ureter dips down into the pelvis, it is less easily located, because it does not bear any fixed relation to a bony landmark; but fortunately, in the cases in which a stone in the ureter is sought for, we have as a guide a hard body that is readily palpable. To reach the ureter in the upper part of its course, perhaps no better incision can be chosen than that proposed by Israel: A line is drawn from a point on the anterior edge of the sacro-lumbar mass of muscles, just below and parallel to the twelfth rib, toward the middle of Poupart's ligament, to the line of incision usually made for tying the iliac artery; thence again toward the middle line and ending at the external border of the rectus muscle. According to the seat of the calculus, the incision will be made on the posterior, middle or anterior third of this line.

Dr. Edmund E. King, of Toronto, made an "Exhibition of Complete Double Ureters of Both Kidneys." He also stated that at ten post-mortem examinations made, he had discovered three cases of supernumerary ureters.

Dr. George E. Brewer, of New York, read a paper on "The Dry Poultice in the Treatment of Epididymitis." He called attention to a method of treatment that he had found very useful in the management of acute and chronic epididymitis. The inflamed testicle is covered with a thick layer of cotton-wool, which is surrounded by a layer of rubber protective tissue extending beyond the cotton to the healthy skin of the scrotum; a gauze bandage is next snugly applied and the whole is held in place and supported by a suspensory bandage. By this means the heat and moisture, retained by the impervious rubber tissue, act in the same manner as an ordinary poultice. The relief to pain afforded by this method of treatment is often strikingly prompt; but its chief advantage lies in the fact of its marked influence in promoting the rapid dissipation of the inflammatory induration, often so difficult to accomplish. Between twenty-five and thirty cases of epididymitis had been treated in the manner indicated, with most satisfactory results. In nearly all, the relief of pain was prompt; and in all, the absorption of the induration was strikingly apparent.

Dr. John P. Bryson, of St. Louis, inquired whether this method of treatment caused the disappearance of the little fibrous nodules that form, or lessened the number of them.

Dr. James P. Tuttle, of New York, asked how much pressure should be applied in bandaging the testicle.

Dr. Brewer stated that he had not noticed the disappearance of the fibrous nodules referred to by Dr. Bryson. The cases were in hospital patients, and soon lost sight of. In reply to Dr. Tuttle's question, Dr. Brewer said that only a moderate degree of pressure should be employed.

Fourth Day—September 25th.

Dr. John P. Bryson, of St. Louis, read a paper on "The Radical Cure of Urethral Stricture by Restoration of the Mucous Membrane to a Healthy Condition." He defined stricture of the urethra as a chronic contracting peri-urethritis, caused by the leakage of the urine or of some of its constituents through a damaged or absent mucous membrane. Urethral stricture may be inflammatory or cicatricial. In the first the mucous membrane, damaged though it be, is still present; in the second the mucosa has been replaced by cicatricial tissue. Any therapeutic procedure, therefore, must aim primarily at a restoration of the mucous membrane to a normal condition.

Dr. Bryson said that his method of treating stricture was based upon the theory that if the mucosa could be restored to a normal condition while the constricting band was undergoing softening and inflammatory involution, a radical cure could be hoped for. Linear strictures are often permanently benefitted by the use of the sound alone, but this is entirely inadequate in case of annular strictures. Dr. Bryson then reported the history of a case of annular stricture that was treated by cutting and divulsion with only temporary relief, and that finally was permanently cured by intermittent dilatation combined with topical treatment directed to the restoration of the mucous membrane.

Dr. L. Bolton Bangs, of New York, read a paper on "The Treatment of Urethral Stricture." He defined as stricture an unnatural narrowing of the urethra in any part of its length. The bulbous portion of the urethra is the largest in caliber, not only in the adult, but also in infants, and is capable of the greatest degree of physiological distention. Dr. Bangs reaffirmed his belief in the principle formulated by Dr. Otis, namely, that the caliber of the human urethra is proportionate to the circumference of the penis. He considered the treatment of strictures by divulsion both unsurgical and unscientific. The influence of the instrument is distributed more or less beyond the strictured areas, and the resulting cicatrix is irregular and often decidedly contracting. He also does not approve of electrolysis. When a current is employed sufficiently strong to have any effect upon the tissues at all, it acts as an irritant and gives rise to inflammatory deposits. Dr. Bangs regards gradual dilatation as sufficient for soft, non-fibrous stric-

tures of the posterior urethra, or of the bulbous or penile urethra; but for all strictures of large caliber requiring interference, he advocates treatment by internal urethrotomy and thorough division. If the stricture is of small caliber, or is complicated by fistulæ, either in the penile urethra or perineum, or if there be indurated cicatricial deposits deeper than four and a half inches, he advocates, in conjunction with internal urethrotomy, an external perineal urethrotomy combined with prolonged perineal drainage.

DR. JAMES P. TUTTLE, of New York, read a paper on "The Treatment of Urethral Stricture and Its Resulting Conditions by Extreme Gradual Local Distention and Without Cutting, Including a Brief *Résumé* of Fifty Cases." He said that perhaps the best practical definition of stricture is that of Dr. White: "Stricture is an abnormal lessening of the caliber or the dilatability of the urethral canal, associated with changes in the mucous, muscular, or submucous structure constituting its walls." Dr. Tuttle stated that he had made measurements of the stretched mucous membrane of the urethra in fifty cadavers and in more than one hundred living subjects with healthy urethræ. In all cases certain constrictions and dilatations were found, more or less uniform, and no doubt perfectly normal. These natural anatomical conformations demand careful consideration and conservatism. Dr. Tuttle stated that he had practised internal dilating urethrotomy for eight years, but more recently he had abandoned the cutting operation in most cases, substituting extreme local dilatation at the point of stricture. To accomplish this end Dr. Tuttle devised a new instrument, called a urethral dilator, which he has used for more than a year, and with which he has obtained good results.

DR. ROBERT W. TAYLOR, of New York, stated that the profession is apt to run to extremes in the treatment of strictures. To Dr. Bangs is largely due the credit of introducing perineal urethrotomy, which is a most admirable and beneficial procedure in certain cases.

DR. W. K. OTIS, of New York, said that in cases in which the stricture was situated far back in the urethra, and surrounded by hard, cicatricial deposits, it seemed useless to attempt the removal of these by any but the surgical method of external urethrotomy.

DR. JOHN A. FORDYCE, of New York, stated that he considered Dr. Bryson's definition of stricture—a chronic contracting peri-urethritis—an excellent one, but, in his opinion, it did not always depend upon an infiltration of urine; in some instances, it was caused by the entrance of gonococci (or the chemical products to which they give rise) into the glandular or epithelial tissues.

DR. W. FRANK GLENN, of Nashville, read a paper on the "Treatment of Gonorrhea," in which he related that he has met with great success in the treatment of gonorrhea by the use of mild solutions of chloride and iodide of zinc. The strength usually employed is one-half grain of chloride and one grain of iodide to the ounce of water. This solution, which can be further diluted if necssary, is to be injected into the urethra three or four times daily.

DR. TAYLOR said that the personal element entered largely into the treatment of gonorrhea; others cannot always obtain similarly good results from the same course of treatment. He considered chloride of zinc useful in some cases in the declining stages of urethritis, but he would be loath to use it deep down in the canal.

DR. WILLIAM JUDKINS, of Cincinnati, stated that he has had great success in some cases by applying the yellow oxide of mercury on a sound, or by introducing it into the urethra on a pledget of cotton.

DR. OTIS said that he had given salol an exhaustive trial, but was only successful in discoloring the urine.

AMERICAN ORTHOPEDIC ASSOCIATION.

Fifth Annual Meeting, held at Washington, September 22, 23, 24, and 25, 1891.

(Continued from p. 382.)

THIRD DAY—SEPTEMBER 24TH.

DR. A. B. JUDSON, of New York, read a paper upon "Malignant Disease of the Vertebræ Simulating Pott's Disease." Three cases were reported in which Pott's disease and malignant vertebral disease had been confounded by himself and other observers. The first patient, a boy of four years, died three months after the appearance of the symptoms. The other patients, men, aged respectively thirty-five and forty-two years, survived the first symptoms one or two years. In each case an autopsy was made, correcting the *ante-mortem* diagnosis in two cases and confirming it in one. In no case was there distinct kyphosis. In two cases there was paraplegia, the paraplegia dolorosa of malignant disease and not that of Pott's disease. The chief symptoms were general prostration, pain, and disability, located in the back. These patients were very ill, which cannot well be said of most patients affected with Pott's disease. They had severe pain and extreme disability in the back, from which Pott's disease is so free that when we hear of pain in the back and spinal disability, the first thought is to eliminate spinal caries. In brief, the chief differential points are: (1) Deformity, present in Pott's, absent in malignant disease; (2) Local disability, and (3) Local pain, both absent in Pott's and present in malignant disease.

The paper of DR. CHARLES L. SCUDDER, of Boston, on "Paralysis in Pott's Disease," was read by Dr. WILLIAM L. BULLARD, of Boston. The case recorded by Dr. Scudder is unique from the existence of hydrocephalus, together with spina bifida, rotary lateral spinal curvature, while the mental condition was unimpaired. Dr. Scudder called attention to the necessity of dividing tendons, when possible, near enough to the muscular belly to maintain a connection between the severed tendon and its muscle, thus preventing a matting together of the tendons in their sheaths, as happens when the division is made lower.

Dr. Bullard expressed the belief that the contractures due to spastic paraplegia must be carefully distinguished from those due to other causes. They are totally different from the contractures found in old cases of anterior poliomyelitis, the so-called paralytic contractures, and are not to be confounded with the conditions existing in congenital varus and club-foot, which are usually due to wholly different causes. He is inclined to believe that the spastic paraplegia is not directly due to any effect on the cord occasioned by the spina bifida, but is the direct result of the accompany-

ing hydrocephalus. The exact steps by which this result is brought about are not yet wholly known.

Dr. Samuel Ketch, of New York, in a paper upon "Prognosis in Pott's Disease," considered the subject from the following standpoints: 1. Regional prognosis; 2, age of the patient; 3, etiology; 4, complications, and 5, thoroughness of treatment. Seventy-five cases taken from the case-books of the New York Orthopedic Hospital were analyzed with the following results: 37 were males, 38 were females; 28 cases were from 1 to 5 years of age; 31 cases were from 5 to 10 years of age; 16 cases were above 10 years of age.

The average time of treatment in obtaining a cure was: for disease in the superior region, $26\frac{1}{5}$ months; in the middle region, $64\frac{8}{25}$ months; in the inferior region, $47\frac{1}{25}$ months.

As a complication, abscess was frequent in disease in the middle and inferior areas, developing in the course of the disease in nearly 50 per cent. Paraplegia may be looked for more frequently in disease of the superior and middle areas; rarely in disease in the inferior.

In some cases recession of deformity had occurred under treatment, but the prognosis as to the recession of the kyphosis was uncertain. As a rule, better results, as regards deformity, could be expected in disease of the superior and inferior regions.

In order to obtain good and permanent results, treatment must be long continued. Dr. Ketch cautioned against the tendency to remove apparatus early. Under thorough mechanical treatment, abscess is frequently prevented, and, when present, often disappears, thus favorably influencing the eventual prognosis.

Dr. B. E. Hadra, of Galveston, read a paper entitled "Proposed Treatment of Pott's Disease by Wiring the Vertebral Processes." He described his method of wiring the spinous process, the subject being considered from a theoretical standpoint. The proposed method is already well known to the American profession.

Dr. De Forest Willard, of Philadelphia, read a paper on "The Operative Treatment of Tuberculous Caries of the Spine," giving as the indications for surgical interference: (1) Pus accumulations; (2) the removal of carious bone; and (3) the relief of paraplegia.

The following are the conclusions at which he had arrived: (1) After ankylosis has resulted, recumbency, extension, suspension and support of the diseased vertebræ are important means to obviate the necessity and to further the success of operative procedures. (2) Dormant and caseating foci may well be treated on the expectant plan. (3) Liquefying and caseating collections should be tested with the aspirator and injected with iodoform emulsion; the operation being repeated unless pus is discovered. (4) If sero-purulent fluid is withdrawn, injections may still be relied upon to assist the system in conquering and limiting the tuberculous process. (5) When pure pus is present the abscess should be incised, the cavity washed out by a long-continued flow of hot sublimate solution, but manipulation should not be practised upon the walls of the sac lest a fissure be occasioned and entrance of tuberculous poison into the system be facilitated. The incision should be carefully sutured and from thirty to sixty grains of iodoform dissolved in boiled olive oil should be injected and retained in the cavity. (6) When the situation of the abscess is in the lumbar region and the case permits of a thorough removal of the sac, the abscess should be incised and its walls, together with all tuberculous tissue, should be removed with knife, scoop and scissors. (7) Drainage-tubes should not be retained longer than necessary, as they may give rise to the formation of sinuses. (8) When excision of the wall is impossible, free incision and drainage, coupled with iodoform injections, are palliative and will assist in facilitating the removal of the diseased tissue. (9) Excision of diseased bone-tissue is feasible, when this is situated in the arches, and occasionally in the lumbar region when the articular and transverse processes or the side of the body is affected. (10) The preceding is an operation limited in scope, and should be practised only in the cases mentioned. For purposes of drainage, however, it is beneficial.

For the relief of pressure-paralysis the laminæ are to be removed only after a thorough trial and failure of long-continued horizontal extension, counter-extension and fixation, unless dissolution is rapidly threatened. In the majority of cases of pressure-paralysis, recovery takes place after extension and mechanical treatment. The removal of the laminæ is troublesome except in the upper dorsal region, and entails considerable risk to the patient. In caries of the arches, and when the cord is compressed from behind, it is certainly justifiable. When the pressure is anterior, either from deposit of caseous material, from tuberculous infiltration, or from inflammatory deposit, no permanent benefit will be secured, even though temporary gain is apparent.

Mr. Howard Marsh, of London, spoke particularly of laminectomy, which he considered of diagnostic value.

Mr. Howard Marsh, of London, read one of the most interesting papers of the session upon "Pott's Disease in Middle and Advanced Life." He admitted that in a large majority of cases tuberculosis commences between the ages of three and nine, but he had seen several instances in which it had developed in infants under a year old, and in at least two infants under eight months old. It may also occur (though more and more rarely as years advance) at any subsequent period up to extreme old age. At a still later period, in persons over sixty, surgical tuberculosis still occurs, though with increased rarity.

Mr. Marsh stated that his experience accorded with that of Sir James Paget, who, in a paper on "Senile Struma," remarks that persons over sixty are more often scrofulous than those between thirty and fifty, and adds that there is not one of the so-called seats of election of scrofula in the young (lymph-glands, bones, joints, the spine, the testis, and other parts) in which he has not seen the disease in persons over sixty. Of all the forms of tuberculosis in persons over sixty, however, Mr. Marsh found Pott's curvature the most rare.

In conclusion, he believed that the diagnosis between tuberculous disease and osteo-arthritis in these instances could readily be made.

Cases of tuberculous disease do not, as a rule, present disease of more than one part. It is not known that osteo-arthritis produces angular curvature. In many cases suppuration occurs, a result rare in osteo-arthritis. So trustworthy an observer as Sir James Paget states

that he has himself met with tuberculous disease of the spine in old subjects. In the College of Surgeons there is a specimen of the cervical vertebræ removed from the body of Dr. Buckland, dean of Westminster. The osseous structure of the lateral masses and adjacent parts of the atlas and axis is deeply eroded and excavated, and the two bones are displaced in relation to one another. Thus the appearances exactly accord with those that are found in caries of the spine in childhood. The dean at the time of his death was seventy-two. He died of general weakness and melancholia, and the spinal disease was not suspected during life. No statement is made in the museum catalogue as to the nature of the disease, but Mr. Marsh thinks there can be no reasonable doubt that it was tuberculous. There can be no doubt that tuberculous disease of other parts is by no means very rare in the old. These cases are exactly similar to cases of tuberculous disease of the spine as seen in the young.

DR. L. A. WEIGEL, of Rochester, read a paper upon "Cervical Spondylitis," and reported a case in a boy, eight years of age, in which the severity of the symptoms compelled the patient to maintain the recumbent posture; but no improvement in the paralytic symptoms followed. Subsequently a retro-pharyngeal abscess developed. After treatment by recumbency, combined with weight-traction, rapid improvement in the symptoms took place and in the course of a few months the boy completely recovered. The points of interest in the case are: 1, the long continuance of the paralytic symptoms, notwithstanding the enforced recumbency; 2, the simultaneous existence of paralysis and abscess; 3, the rapid improvement under treatment by extension combined with recumbency.

DR. BENJAMIN LEE, of Philadelphia, read a paper on "The History of the Use of Suspension in Pott's Disease." He claimed the distinction of having been the first to propose, and to use in the treatment of Pott's disease, self-suspension by means of a cord and pulley attached at some distance above the head, the other extremity of the cord being placed in the hands of the patient. He maintained that in all cases of paralysis accompanying or resulting from spinal caries, the use of some form of mechanical splint, in conjunction with suspension, will permit a successful result to be more rapidly, more surely, and more perfectly obtained.

DR. AP MORGAN VANCE, of Louisville, read a paper upon "Recumbency in the Treatment of Pott's Disease," in which he expressed the belief that surgeons often overlook the possible good of temporary treatment by recumbency, when mechanical treatment has failed to relieve the symptoms or when circumstances prevented the proper use of a portative appliance. Dr. Vance has seen more rapid improvement of the bony lesion in cases of paralysis in which recumbency has been enjoined, and in other cases in which intercurrent disease has necessitated this position for a long period. Objections to this mode of treatment are frequently made by practitioners and parents on the plea that the general health will suffer. Dr. Vance has yet to see any bad results from it, the children usually improving and particularly if attention is given to massage of the extremities and proper feeding. This temporary detention in bed, he believes, is often the turning-point toward recovery, and the difficulties otherwise experienced in the mechanical are no longer encountered.

DR. CHARLES C. FOSTER, of Cambridge, Mass., read a paper on "Extension in Bed in the Treatment of Caries of the Spine," in which he said that extension is applicable in caries of all parts of the spine, but is especially useful in caries of the cervical region. Extension reduces deformity, relieves pain, subdues inflammation and removes the liability to abscess, thus making the disease less exhausting to the patient, shortening its duration and minimizing the amount of repair necessary. Bed is the proper place for a patient during the active stage of caries. It is said that a child will pine if denied fresh air and exercise. Dr. Foster is sure that children *with carious joint-disease* will thrive in bed for months at a time; but when so confined they need constant attention. Motion must be reduced to a minimum, and the patient should be handled gently and carefully. The child soon learns the benefit of quiet and ceases its attempts to move.

Extension is obtained by weights, the cords running over the head and the foot of the bed, and being attached to waist-belts, chest-belts or Sayre head-straps. Surprisingly light weights are required. Such treatment cannot be carried out in out-patient or tenement-house cases; but this is the fault of the cases, not of the treatment. Such cases should not constitute a standard. Their treatment is, and must be, makeshift rather than ideal. From time to time the condition of the spine may be best studied and the progress of the disease appreciated by palpation of the affected vertebræ, a delicate and difficult procedure, but exceedingly valuable.

DR. REGINALD H. SAYRE, of New York, read an interesting and valuable paper on "Traction and Fixation in Pott's Disease," which will appear in a future number of THE MEDICAL NEWS.

The paper of DR. V. P. GIBNEY, of New York, upon "Traction and Fixation in Pott's Disease," was read by title, and will appear in a subsequent number of THE MEDICAL NEWS.

DR. E. H. BRADFORD, of Boston, read a paper on the "Comparative Value of the Prevalent Methods of Treatment of Caries of the Spine," in which he said that the treatment of caries of the spine must necessarily be based on the pathological conditions present; as these vary, the treatment must necessarily vary. The plan of treatment should also be adapted to the portion of the spinal column affected, for the caries of the spine differs somewhat in its course in different portions of the spinal column.

The methods of treatment may be grouped as follows: by recumbency; by mechanical appliances; and by plaster bandages and corsets.

Treatment by recumbency is of great value in the acute stages, and is indicated whenever patients find great disability in going about, and are disinclined to walk or run, and are more contented when lying or sitting down. The recumbency should, however, be thorough; the patient should be kept upon the back, with a proper arrangement of pads, so that sloughing be prevented. He should be fixed, by means of a frame or straps, so that sitting up or turning in bed should be impossible; and it should be so arranged that the patient can be carried about freely, so as to be given the benefit

of fresh air. Traction by weight and pulley applied to the limbs or to the neck is sometimes of great assistance. The necessary limits to the benefit to be derived from recumbency are determined by the patient's general condition. It is manifestly impossible that the patient should remain in the recumbent posture until cicatrization has taken place, as this process involves years. For this reason the treatment by recumbency is only the treatment of a stage. When patients begin to appear apathetic and listless, when general nutrition seems to fail, after they have been kept recumbent for a long time, this treatment should be discontinued. Recumbency, by which is also meant fixation, will be found to be the most efficient means of preventing increase of the curvature.

Mechanical appliances are an essential part of the treatment of caries of the spine; for whether recumbency is maintained or not, at some stage some form of mechanical appliance, either a corset or a brace, must be used in order to enable the patient to go about without danger to his back.

The form of mechanical appliance will necessarily vary according to the region of the spine affected, but Dr. Bradford has found one constructed upon the principle of the antero-posterior support most serviceable. When head-supports are necessary he uses both the jury-mast, the wire chin-support, and the Thomas collar, or the Taylor oval ring; the latter being on the whole preferred in the majority of cases in which care can be given in adjusting it. The jury-mast is equally efficient, but has the objection of unsightliness.

Treatment by mechanical appliances has the disadvantage of requiring skill and experience on the part of the surgeon, and attention on the part of the parents, Given these conditions, however, it furnishes the most efficient means of treatment with portable apparatus; and the patients can be thoroughly treated in this way. in many instances, without recumbency at all.

The value of plaster-jackets is very great, and for the ordinary treatment of hospital cases to which great care cannot be given by the parents, the plaster-jacket alone may be considered the most ready means of treatment. Skill and care are required to properly apply plaster-jackets, which have the disadvantage of uncleanliness and discomfort. The split corset, or leather corset, or wood corset, or cloth corset, stiffened by wire, is of value in the stage of convalescence, the latter being of the least value, but in the acute stages the permanent corset is preferable.

Caries of the spine is the most curable of affections, but requires treatment for a long time to insure a perfect cure, the disease running its course in from three to five years.

Fourth Day—September 25th.

Dr. Bernard Bartow, of Buffalo, read a paper on "Treatment of Pott's Disease, with Especial Reference to the Early Stage," in which he said that when treatment was begun in the early stage, better results would be obtained than when begun at a later stage. Then the focus of the disease was small; the shape of the vertebra was unchanged; restraint from movement was more likely to encapsulate the focus. Complete arrest of the disease, without the formation of angular deformity, might be expected in the greater number of cases.

Dr. V. P. Gibney, of New York, read a paper entitled "A Further Contribution to Typhoid Spine." He reported a case of typhoid spine in a man, aged forty-five, which had existed for twenty-three years, and in which the cervico-dorsal region was involved. The conditions presented were practically the same as those previously reported as characteristic of this condition.

Dr. E. H. Bradford, of Boston, read a paper on "The Treatment of Congenital Dislocations at the Hip," and showed photographs of appliances for the treatment of this condition after the method of Dr. Buckminster Brown. The modifications of Brown's method were such as to allow the patient to be carried about, but not to stand. When convalescence is established, protective walking-apparatus made of aluminum is applied.

Dr. Bradford also read a paper entitled "Means of Recording Rotation in Lateral Curvature," and showed photographs of his method of recording rotation in lateral curvature, and described the different methods of its application.

Dr. Bradford also read a paper entitled "Modifications in the Treatment of Lateral Curvature," and showed photographs of appliances for increasing the flexibility of the spinal column in lateral curvature as preliminary to the use of plaster-jackets or other corsets.

Dr. N. M. Shaffer, of New York, read a paper on "Elongation of the Ligamentum Patellæ as a Factor in the Production of Certain Knee Troubles and Difficulties in Locomotion," and reported a number of unique and interesting cases in which from various causes the patellar tendon had become elongated.

Dr. Royal Whitman, of New York, read a paper entitled "Observations on Torticollis, with Particular Reference to the Significance of the So-called Hematoma of the Sterno-mastoid Muscle," which is to appear in The Medical News. From a review of the literature, and from clinical observation, he had concluded that congenital torticollis was usually of intra-uterine origin, and not, as stated by many writers, the result of injury at birth. He presented a report of 264 cases of torticollis, showing the affection to be more frequent in females than in males, and that the sides of the neck are equally liable, although the opposite opinion usually prevails.

Dr. George W. Ryan, of Cincinnati, read a paper on "Rheumatic Spondylitis," in which he said that the symptoms were difficulty in locomotion, rigidity, and pain; later, a rounded kyphosis, suggesting tuberculous spondylitis, but distinctly different in its character. The prognosis is bad. The treatment is aimed chiefly to the relief of the pain, and consists of support, local blisters, the Paquelin cautery, and internal medication. A case was reported in detail, and photographs illustrating the deformity were shown.

Dr. V. P. Gibney, of New York, read a paper entitled "The Definition and Scope of Orthopedic Surgery," in which he endeavored to show that the limitations placed upon the orthopedic surgeons by Dr. Shaffer in his paper "What is Orthopedic Surgery?" were not acceptable to the majority of American orthopedic surgeons. Dr. Gibney maintained that the orthopedic surgeon should be competent and feel free to treat any case of chronic joint-disease or deformity by any means whatsoever, mechanical or operative, and without assistance to carry

it on to a successful issue. In many cases the mechanical after-treatment was of more importance in preventing a return of the deformity than was the operation, and it was not right to turn a case over to the operative surgeon for the operation when he lacked the knowledge to properly carry out the mechanical after-treatment. The orthopedic surgeon should feel competent to manage his cases himself, and independent of any assistance at the hands of the general surgeon.

DR. P. REDARD, of Paris, read a paper on "The Relation of Scoliosis to Club-foot." He insisted upon the importance of a study of the causes of spinal curvature from the point of view both of prognosis and of treatment. He maintained that in a large number of cases of scoliosis an evident relation exists between club-foot and the spinal curvature. The inequality of length of the lower extremities dependent upon club-foot occasions the assumption of vicious attitudes, which in turn are followed by actual scoliosis. Next to vicious positions assumed in writing, club-foot is one of the most frequent primary causes of scoliosis. In all cases of incipient scoliosis it is important to examine the lower extremities, so as to determine whether or not club-foot or any other cause of inequality of length of the members exists.

DR. F. BEELY, of Berlin, read a paper on "The Pathological Anatomy of Lateral Curvature of the Spine," in which he said that traction and pressure may cause an increase or a cessation of the development of osseous tissue in a vertebra, increasing the horizontal diameter, diminishing the thickness on the side of the pressure and increasing it on the side of the traction. The differences between the vertebræ of the adult and those of the child were pointed out, and it was shown how pressure and traction, acting during the process of growth, lead to the deformed vertebræ that are found in scoliotic spines. The differences in the mechanism of rotation in the kyphotic spine and in lordosis, and the causes of the narrowing and widening of the inter-spinous sulci, were pointed out.

DR. DE FOREST WILLARD, of Philadelphia, read a paper on "Operative Treatment of the Deformities Resulting from Infantile Spinal and Cerebral Spastic Paralysis," which will appear in THE MEDICAL NEWS. In illustration he reported five cases of anterior polio-myelitis and three of birth-palsy dependent upon organic cerebral disease. As a result of his observations he maintained that many apparently hopeless cases could by appropriate treatment be put upon their feet. However great the deformity, an attempt at correction should be made, so as to enable the individual to walk. Atrophied limbs can be straightened, and then be provided with apparatus for locomotion. Even greatly atrophied limbs may be developed by exercise. The improvement will be continuous. In most cases, however, better results are secured more quickly and more readily by surgical than by mechanical means. Treatment should be instituted early, in order to obviate pain and to save time. Tenotomy and myotomy cannot remove the causal disease, but the results obtained are promotive of the health and happiness of the individual. The deformities of infantile paralysis are preventable by the use of suitable apparatus; but when the deformity has occurred, such surgical measures should at once be instituted as will enable the patient to walk. Deformity is more apt to recur in cases of spastic paralysis than in cases of infantile paralysis.

DR. L. A. WEIGEL, of Rochester, read a paper entitled "The Operative Treatment of Spastic Paralysis," in which he reported a case in the person of a girl of fourteen years, upon whom he had operated and then applied a brace, with most satisfactory results. The paper is to be published in THE MEDICAL NEWS.

DR. BENJAMIN LEE, of Philadelphia, read a paper on "Injuries to the Sacro-iliac Junction." Such injuries, attended with imflammation, he maintained were apt to occur in obese women, especially as a result of falls upon the buttock or hip. Lameness and sciatica are the most conspicuous symptoms. The best treatment is strong lateral compression of the pelvis—splinting the pelvis. To avoid the necessity of stooping on the part of the patient, Dr. Lee has devised an appliance called a "teledactyl" (long finger), consisting of a spring-forceps at the end of a cane, operated by a cord passing to the handle and provided with a ring for the index-finger. By means of this device objects of moderate weight, and as small as a pin, can be prehended.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF THE MEDICAL CORPS OF THE U. S. NAVY FOR THE TWO WEEKS ENDING SEPTEMBER 26, 1891.

HOEHLING, A. A., *Medical Inspector.*—Ordered as a member of Medical Examining Board.

HARMON, G. E. H., *Surgeon.*—Ordered to the U. S. S. "Yorktown."

BOYD, JOHN C., *Surgeon.*—Detached from the U. S. S. "Yorktown," and granted leave.

DUBOIS, F. L., *Medical Director.*—Detached from Navy Yard, Portsmouth, N. H., and wait orders.

AYERS, J. G., *Surgeon.*—Detached from the U. S. S. "Wabash," and ordered to Navy Yard, Portsmouth, N. H.

CORDEIRO, F. J. B., *Passed Assistant Surgeon.*—Ordered to the U. S. S. "Wabash."

NORTON, O. D., *Passed Assistant Surgeon.*—Ordered to the U. S. S. "Petrel."

HALL, JOHN H., *Surgeon.*—Ordered to appear before the Retiring Board.

MARSTELLER, E. H., *Passed Assistant Surgeon.*—Detached from the U. S. S. "Petrel," and granted one month's leave.

NORTON, O. D., *Passed Assistant Surgeon,*—Detached from special duty at Naval Academy, and ordered to the U. S. S. "Petrel."

HALL, J. H., *Surgeon.*—Detached from Naval Hospital, Chelsea, Mass., and placed on waiting orders.

BRADLEY, G. P., *Surgeon.*—Ordered to Naval Hospital, Chelsea, Mass.

GRAVATT, C. U., *Surgeon.*—Ordered to Naval Hospital, Brooklyn, N. Y.

GARDNER, J. F., *Passed Assistant Surgeon.*—Detached from Naval Hospital, New York, and ordered to the Naval Station, New London, Conn.

NORTH, J. H., *Assistant Surgeon.*—Detached from Navy Yard, New York, and wait orders.

LUNG, GEORGE A., *Assistant Surgeon.*—Detached from Naval Station, New London, Conn., and ordered to the Navy Yard, New York.

SIMONS, M. H., *Surgeon.*—Detached from the "Enterprise," and to hold himself in readiness for sea-service.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment, provided that the request for reprints be noted by the author at the top of the manuscript. When necessary to elucidate the text, illustrations will be provided without cost to the author.

Address the Editor: GEO. M. GOULD, M.D.,
1004 WALNUT STREET,
PHILADELPHIA.

ORIGINAL ARTICLES.

A CASE OF FRACTURE OF THE TWELFTH DORSAL VERTEBRA, FOLLOWED BY INJURY TO THE SPINAL AND SYMPATHETIC NERVE-SUPPLY OF THE BOWEL IN THE REGION OF THE ILEO-CECAL VALVE;

Intestinal Hemorrhage and Death on the Seventh Day.[1]

BY J. T. ESKRIDGE, M.D.,
OF DENVER, COLORADO.

M. J. A., male, thirty-three years of age, born in Illinois, by occupation a carpenter, a robust, muscular fellow, had enjoyed excellent health until the time of the accident that was the cause of his death. On July 9, 1890, whilst engaged in work on a large nine-story building in Denver, a cage with its contents of brick, weighing about two thousand pounds, as it was passing over him only a few feet above his head, fell, striking him on the crown of the head, and carrying his head between his feet and bending the spine sharply backward in the dorso-lumbar region. The rope by which the cage was suspended did not allow it to descend nearer the floor than about eighteen inches. The man was imprisoned between the cage and the floor only a few minutes, but when released he was unconscious and remained so about half an hour. On regaining consciousness his legs felt numb and were paralyzed for two hours. He was removed to the Arapahoe County Hospital, where I saw him four hours after the occurrence of the injury. An examination showed that there were neither paralysis, sensations of numbness, nor loss of tactile sense in any portion of the body or limbs. There was no incontinence of urine, but he was unable to expel the contents of the bladder. The back, at the junction of the dorsal and lumbar vertebræ, was arched backward and the soft tissues over the upper lumbar and four lower dorsal spines were greatly swollen and acutely sensitive to the touch. He complained of great pain in this portion of the back and said that he had uncomfortable sensations in the lower portion of the abdomen. His temperature was 100.4°; the pulse, 100; respiration, 24. A cloth saturated in a lotion of equal parts of laudanum, arnica, and aconite (tincture) was applied over the sensitive portion of the back, and a surface, ten by four inches, was covered with a thick ice-poultice (equal parts of pounded ice and bran). His suffering was so great that it required half a grain of morphine, hypodermatically, to relieve it. The next morning he was feeling quite comfortable. The back was free from pain so long as he was left undisturbed. He evacuated his bladder without assistance. The urine was free from albumin and sugar. He enjoyed his breakfast, which consisted of eggs, toast, and milk. His temperature was now 100.4°; respiration, 18; and pulse, 80. In the evening his temperature went up to 101°, but he felt comfortably and ate well. No morphine had been required since the night of his admission into the hospital. The ice-poultice was continued.

During the next four days he continued to improve. His temperature varied from 99° to 100.3°. He ate well and had no difficulty with the bowels or bladder. By the end of the fifth day (July 13th) the swelling and tenderness in the back had nearly all disappeared, and slight crepitus could be detected over the spine of the twelfth dorsal vertebra. The temperature in the morning was normal and in the evening was 99.5°. The improvement continued until about noon of the sixth day after the accident, when he ate quite freely of boiled cabbage, which, contrary to orders, had been served to him by one of the porters of the hospital. Two hours after partaking of the cabbage he began to vomit and continued to do so every few minutes for several hours. The vomitus, at first, consisted of undigested food, including cabbage, then of mucus, and lastly of a dark coffee-grounds-looking substance. He complained of great pain in the stomach and in the lower portion of the abdomen. His strength failed rapidly, and the next morning he was in a state of profound collapse. I saw him at 11 o'clock. His temperature was 101°; pulse, 160; and respiration, 48. His bowels had been opened twice the day before, after eating the cabbage, but not at all that morning. His abdomen was irregularly and greatly distended, especially from the umbilicus downward and to the left. Death took place twenty minutes later (11.20 A.M.), consciousness continuing to the last.

Sectio cadaveris at 12.30 P.M., one hour after death, in the presence of Drs. Davis, Boice, and Baker. The brain was not examined. The heart and lungs were nearly normal in appearance and free from disease. On opening the abdominal cavity no peritoneal inflammation was found and the cavity did not contain an undue amount of fluid. On superficial inspection, the stomach, bowels, and other viscera presented a normal appearance, except the lower portion of the ileum and the upper portion of the colon. This portion of the bowel was enormously distended, almost black in color, and accounted for the irregular distention of the abdomen that I had observed a few minutes before death. The stomach was not inflamed, but it contained several ounces of watery fluid stained with blood. On slitting open the small intestine from above down-

[1] Paper read at the meeting of the American Neurological Association, held in Washington, D. C., September 22–25, 1891.

ward, nothing abnormal was found except a small quantity of fluid colored like that found in the stomach, until the lower portion of the ileum was reached. At a point five inches above the ileo-cecal valve, the bowel was abruptly distended to its utmost, and the swollen mucous membrane seemed to completely occlude the caliber of the bowel at this point, so that none of the contents of the distended portion of the intestine could reach the undistended portion. The distention reached from a point in the ileum five inches above the valve to a point in the colon six inches below the valve, and ended as abruptly below as it had begun above, and the swollen mucous membrane below prevented the escape of the contents of the distended bowel into the gut below as effectually as was the case at the upper portion of the distention. A ligature was thrown around the bowel above and below the distended portion, which was excised for further examination. The remaining portion of the colon was examined and found normal. It was not stained with blood. The intestine immediately above and below the seat of distention seemed contracted and considerably smaller than normal. On examining the excised portion of the bowel, which was of a bluish-black color, it was found to be eleven inches in length and six inches in diameter at the seat of greatest distention, a point just below the ileo-cecal valve. This portion of the bowel contained a little over two quarts of dark, semi-fluid blood. The mucous membrane and other coats of the bowel were almost black, soft, and everywhere infiltrated with dark, fluid blood. The vermiform appendix was dark and everywhere infiltrated with blood, but its blind pouch was not enlarged. None of the other viscera of the abdomen presented anything abnormal.

On exposing the spinal column, both in front and behind, the bone-lesion was found to involve the twelfth dorsal vertebra. After examining the cord, the sixth dorsal and lower lumbar vertebræ were sawn through and the intervening portion of the spinal column with the posterior third of the lower five ribs was removed and a careful dissection made. The soft parts around the body of the twelfth dorsal vertebra were considerably infiltrated with blood and inflammatory products. The twelfth thoracic ganglia of the sympathetic nerve, one of which lies on either side of the body of the vertebra, were surrounded by bloody infiltration and inflammatory products. The ganglia themselves were discolored, softer than normal, and apparently partially or completely disorganized. It was impossible to dissect out the ganglia owing to the infiltration of the parts and to their disorganized condition, hence they could not be obtained for microscopic examination. On further dissection it was found that the anterior portion of the body of the twelfth dorsal vertebra was crushed and a horizontal fracture extended through the entire body of the vertebra, and allowed the bodies of the eleventh dorsal and first lumbar vertebræ to approach anteriorly within half an inch of each other. There was also a backward subluxation of the upper portion of the twelfth costal vertebra, exposing the two superior articular processes of the vertebra, which projected backward nearly half an inch further than the inferior articular processes of the eleventh costal vertebra. As well as could be determined, the ligamentum subflava, the supra-spinous, inter-spinous, and capsular ligaments between the eleventh and twelfth costal vertebræ were ruptured. The ends of the spinous processes of these two vertebræ were separated a distance of about two inches from each other, causing a sharp curve in the spinal canal. The size of the spinal canal was further lessened by the projection backward of the upper and posterior portion of the body of the twelfth costal vertebra. The spinal cord was stretched and flattened from before backward by the angular curvature of the spine and by the fragment of bone projecting into the canal. Only a few drops of blood were found in the spinal canal. Neither the cord nor membranes seemed to be congested or inflamed. The spinal nerves were not compressed by the displaced or fractured bone. That the functions of the cord had been only temporarily affected by the accident, was substantiated by the symptoms. Had the patient survived the accident a few weeks or months, meningitis (local) and myelitis (transverse) would have been the inevitable results of compression and caries.

This is not the time or place for extended comments on the above case, which, so far as my information goes, is unique. I am not aware that any case has been previously recorded illustrating the spinal and sympathetic nerve-supply to the bowel in the region of the vermiform appendix and ileo-cecal valve. The twelfth pair of thoracic sympathetic ganglia receive fibers from the eleventh pair of dorsal nerves, and none from any other of the spinal nerves, if the illustrations in Gray's *Anatomy* are correct. In works on anatomy considerable is said about the distribution of the branches of the sympathetic nerve, but almost nothing, so far as the contents of the abdomen are concerned, in regard to the localization of the spinal and sympathetic nerve-supply of any viscus or portions of the hollow viscera. It is probable that irritation of the eleventh thoracic and first lumbar sympathetic ganglia, caused by infiltration of blood in the soft parts, was the cause of the contraction of the bowel immediately above and below the distended portion. The contraction was so great in the colon immediately following the seat of distention that it made this portion of the bowel appear like a piece of the small intestine.

That internal hemorrhage was the immediate cause of death I do not think there can be any doubt. The cause of the hemorrhage may not, in the opinion of some, be so easily accounted for. It seems to me that in the absence of any other apparent cause, the injury to the twelfth thoracic sympathetic ganglia (which contain both spinal and sympathetic fibers, the one supplying the muscular coats of the bowel and the other the bloodvessels,

glands, etc.), is sufficient to account for the muscular and vasomotor paralysis of the bowel; and probably the irritation set up by the presence of the cabbage and the general disturbance caused by the vomiting were all factors in producing the fatal and localized hemorrhage.

DIABETES MELLITUS GRAVIDARUM.[1]

By HENRY D. FRY, M.D.,
of Washington, D. C.

Gravidity increases the susceptibility of woman to certain diseases, and often changes the type of the malady by accentuating its dangers.

The physiological changes in the blood, in the secretions and excretions, and the nervous and physical alterations that occur in normal pregnancy, present new soil for the development and growth of pathological conditions.

The significance of changes in the urinary excretion is generally limited to considerations of the danger of convulsions. The presence of albumin and casts in urine, with low specific gravity and deficient elimination of solid ingredients, are the changes that warrant such a conclusion. Attention, at present, is claimed by the importance of different alterations: increased flow of urine, increased specific gravity, and the presence of sugar. Augmented flow of urine, with consequent low specific gravity, is considered a normal condition of pregnancy. The presence of sugar in small quantity was found by Blot to exist in one-half of all pregnant women. All nursing and lying-in women had glycosuria, and the proportion of sugar in the urine bore some relation to the activity of the mammary glands. When lactation ceased the sugar disappeared. Diabetes insipidus has been observed to occur during, and apparently dependent upon, pregnancy. Conjugal diabetes is described as a form of the disease affecting husband and wife simultaneously.

Physiological glycosuria and different forms of diabetes must not be confounded with diabetes mellitus gravidarum. Under the title "Puerperal Diabetes," Matthews Duncan reported several cases of his own and as many others as he was able to collect. The report comprises the histories of twenty-two pregnancies in fifteen women, and a study of these contributes mainly to the deductions formed in the present article.

The following case came under the observation of the writer:

The first pregnancy and labor were normal. Diabetes developed about the fifth month of the second pregnancy, followed by death of the child at the seventh month. Premature labor followed, and the mother died on the fifth day.

Mrs. P., thirty-one years of age, a secundipara, with good family history, gave birth to her first child after a normal pregnancy and labor. Subsequently her health remained good, but she was unable to nurse her baby, as the milk did not agree with it. In June, 1880, she became pregnant a second time. In the early part of October she first noticed that she was troubled with thirst, but attributed it to the warm weather. Frequent desire to pass urine next attracted her attention, and this symptom increased until the middle of October. She complained of being easily tired and had great difficulty in walking. In the latter part of October, and several times during November, she suffered from what were supposed to be bilious attacks.

The patient came under the writer's observation on November 18, 1880, complaining of severe headache, slight nausea, and constipation. A specimen of urine, that had been requested for examination, was sent on November 23. Seventy-four ounces had been passed in the twenty-four hours, with a specific gravity of 1045. There were no casts or albumin, but it contained 9 per cent. (nearly half a pound daily) of sugar. Dietetic and medicinal treatment were prescribed. After the latter part of November she was more easily tired, and expressed anxiety about her condition. She went out daily until the early part of December, but spent much of the day lying on the lounge. Dyspnea was complained of on slight exertion and was noticeable in talking. She also complained of a stuffed feeling in the ears and of nausea, which were relieved by the recumbent position. A bright, circumscribed spot was generally visible upon one or other cheek—usually the left. Her pulse was 120, appetite poor, skin dry, and mouth dry and sticky. The average daily excretion of urine and proportion of sugar contained, from November 24th to December 10th, inclusive, were ascertained to be as follows: urine, 79 ounces; sugar, 5 per cent. December 10th, emaciation and weakness increased and breathing more difficult. Weight seven pounds less than in August. December 11th, patient passed a miserable night, and her husband, being alarmed about her condition, sent for me at 9 A.M. I found the pulse rapid and feeble; the breathing short, and the speech jerky. The fetal heart-sounds could not be distinguished. Examination revealed the head presenting, cervix effaced, and os dilated as large as a silver dollar. Labor pains had not been felt. Her condition was so serious that an appointment was made to meet Dr. Busey at 2 o'clock in the afternoon to consider the advisability of emptying the uterus. At 11 o'clock an urgent summons was sent to return to the house, and on arrival I found the head of the infant born. The birth had been painless, and the only sign to attract attention to the fact that labor was progressing was the discharge of liquor amnii about an hour before its termination. The body of the child was delivered and the placenta readily extracted. The uterus contracted well, and very little blood was lost. The infant, a male, was small but well nourished. It had evidently been dead

[1] Abstract of paper read at meeting of American Gynecological Society, held in Washington, D. C., September 22–24, 1891.

for some days, as the epidermis peeled off easily. The mother was greatly prostrated; pulse 150, and feeble, and extremities cold. She was wrapped in blankets, hot applications applied, strophanthus and whiskey given by the mouth, and later, hypodermatic injections of whiskey and digitalis. An injection of morphine and atropine was also administered hypodermatically. The patient slept some, felt relief, but still complained of shortness of breath. At 2 o'clock Dr. Busey saw the case in consultation, and continued to meet and advise with me daily. Stimulants and warm applications were continued, and two and a half grains of extract of ergot in suppository were given every four hours. During the day the pulse was from 120 to 130, axillary temperature 98.2°, and surface cool. Thirst was a promiment symptom; the urine passed in large quantities; the breathing was less labored; the lochia normal; the mind dull, but when aroused, clear. On December 12th the symptoms were milder, and on the 13th the pulse was weaker, the temperature normal, the abdomen tympanitic. In the afternoon the mind was dull and one eye half opened in sleep. The mental condition was that of low typhoid. On December 14th the bowels were moved three times from the effect of calomel triturates. The abdomen was tympanitic. Milk diet was stopped and she was given animal broths and scraped raw beef. The mind became heavier; temperature 99.7; lochia normal. On December 15th the condition was worse; respirations were deep and labored, but not accelerated; eyes retracted; clonic contraction of muscles of chest and arms. At 10 A.M. she was unconscious, almost pulseless, and later in the day died.

FREQUENCY AND DIAGNOSIS.—Judged by the paucity of literature on the subject, we might infer that diabetes occurring during the child-bearing period is an extremely rare complication. We believe, however, that the disease is not so uncommon as it is unrecognized. It may develop during pregnancy, the latter exercising a causal influence, or pregnancy may occur in a woman already diabetic. That peculiar condition of a pregnant woman that is responsible for the development of the disease in one case is likely to be the factor in adding malignancy to a preëxisting mild attack in the other. In explanation of the presumable infrequency of the occurrence of pregnancy in diabetic women, it is asserted that the disease exercises a direct influence upon the female generative functions, producing diminution of sexual energy. Local diseases, inflammatory in character, are common in diabetic women and may lead to sterility. That the complication may occur more often than we are led to suppose, and be overlooked, is evident from the histories of the cases collected by Matthews Duncan. In the first case met with by that observer, the urine was not examined for sugar until after labor, although well-marked symptoms of diabetes were present and the patient's appearance created the gravest alarm. There were marked thirst and polyuria, but it was not until the day after labor that the urine was examined for sugar and its presence revealed the nature of the malady. Death occurred two days later. In many other reported cases the disease was unrecognized, and in some of them during repeated pregnancies, although well-defined symptoms pointed to the probable existence of glycosuria.

In W. L. Reid's case the symptoms of the disease were well marked during pregnancy, and after labor the thirst became so "frightful" that the woman crept on her hands and knees to the water-bottle. Two months afterward her emaciation and weakness led to the suspicion that she was suffering from diabetes. Examination showed that she was passing twenty-two ounces of sugar in the twenty-four hours.

DIAGNOSIS.—To aid in recognizing the affection, glycosuria should be suspected and the urine examined for sugar in all cases of pregnancy presenting obscure symptoms, weakness, emaciation, short breathing, etc. It is a good rule to suspect diabetes whenever a dead child is born without apparent cause. Syphilitic poison is no more certain to destroy fetal life than the diabetic condition. The subjective symptoms of the affection are of little diagnostic value, because they seldom attract the attention that their importance demands. When a woman is suffering from diabetes under other circumstances she consults a physician about her ill-health, but when occurring during pregnancy, the symptoms are made light of, attributed to other causes, or considered incidental to her condition. In my case the patient did not complain of any symptom that led to a suspicion of diabetes, although the disease had undoubtedly existed a month before she came under observation. The diuresis was attributed to the thirst, and the thirst to the warm weather. The importance of the symptoms in connection with her ill-health was not suspected.

In several of the reported cases, disturbance of vision led to the detection of glycosuria.

From the evidence that cases have been overlooked and others accidentally discovered, it is more than likely that diabetes occurring during pregnancy is often unrecognized. Some fatal cases are probably classed among deaths due to unaccountable causes, to shock, embolism, the entrance of air into the veins, etc.

Before taking up for consideration the effect of diabetes upon the pregnant, parturient, and puerperal woman, attention is again called to the influence of the child-bearing process upon the disease. When a predisposition exists to diabetes, pregnancy is liable to act as an exciting cause. It may develop in the beginning of gestation, or be deferred until later, usually about the period of quickening. When

preëxisting, the type of the malady is changed for the worse. The disease is less responsive to treatment than under other circumstances. If, however, it do not progress to a fatal termination before confinement, some hope may be entertained that a favorable change will take place at the end of pregnancy. Often the improvement is marked, and the disease seems held in abeyance until a succeeding pregnancy or some other cause starts it up with renewed activity. Cases are reported of disappearance of sugar from the urine after labor, and with it of diabetic symptoms. Some of the patients remained in good health, while others suffered relapses in a few months, or in subsequent pregnancies.

The aggravation of diabetes by pregnancy sometimes causes the disease to assume an acute form. In the case reported by myself, the duration of the disease, from the appearance of the symptoms to the fatal termination, was only ten weeks.

Other cases reported present well-defined attacks of the intermittent type. Authorities on the subject contest the existence of an intermittent diabetes, and attribute cases reported as such either to the result of malarial poisoning or to a benign type of diabetes, in which sugar disappears temporarily, and reappears on slight provocation. The case mentioned by Bennewitz is stated to be unique in this respect. Other cases of intermittent type are reported by Matthews Duncan, John Williams, and F. A. Packard, which confirm the statement that diabetes, occurring in the child-bearing woman, may assume an intermittent form, notwithstanding the admitted rarity of that type of the disease under other circumstances.

The Effect of Diabetes on Pregnancy, Labor and the Puerperium.—In studying this part of the subject one is immediately impressed with the pernicious influence exerted by the disease upon the function of child-bearing. Pregnancy is frequently interrupted by miscarriage or the premature birth of a dead child. The death of the fetus generally occurs at about the seventh month, but the fetus may not be expelled for one or two months afterward. Excessive development of the child is mentioned in a number of cases. It is impossible to state the exact proportion of pregnancies that end in miscarriage and premature labor, because of the incomplete information furnished in the reported cases. Seventeen women who were affected with diabetes at some time of their child-bearing period, gave a total number of seventy-nine pregnancies. The result was not mentioned in thirty-seven pregnancies. Of the remaining forty-two pregnancies only twenty (48 per cent.) terminated naturally. In two of these the children were feeble and died soon afterward; nine, or 21 per cent., of the pregnancies, ended in miscarriage, and thirteen, or 30 per cent., in premature death of the child. While demonstrating the harmful effect of diabetes upon pregnancy these figures do not represent the exact state of the case. Some of the pregnancies included in the above list occurred in women before they became diabetic; and, on the other hand, it is likely that the result, in most of the thirty-seven cases not mentioned, was normal.

Labor at term, in a diabetic woman, does not appear to deviate from the normal, except when influenced by the large size of the child and excessive quantity of liquor amnii.

Complications arising from a distended bladder are liable to occur during labor and the puerperium.

In cases that change for the better after confinement the symptoms improve in a few days. Sugar disappears from the urine (except the small amount considered physiological) after the first week—sometimes almost immediately. Cases recovering after labor should be carefully watched to prevent a relapse of the disease.

The symptoms after labor in severe cases of diabetes, especially when the child is dead, are those of exhaustion and threatened collapse. The pulse is feeble, and varies from 120 to 150, or more. The surface and extremities are cold. The temperature is normal or subnormal until the approach of the fatal termination, when it rises to 100° or 101°. The labored respiration is generally relieved after the birth of the child. The mental condition is generally blunted, the patient talks incoherently, and is restless. Death is generally preceded by coma for from a few hours to several days.

Prognosis.—The unfavorable prognosis of diabetes is accentuated by the coëxistence of pregnancy. Mild cases assume acute forms, and acute cases rapidly progress to a fatal termination. To this general statement exceptions are met, and cases remain mild and extend through repeated gestations. When the disease exists to an degree sufficient to cause the death of the child the gravest apprehension must be felt for the safety of the mother. Of ten such cases, nine died within eight months after labor, and only one survived with persistent diabetes. The birth of a healthy child at term, in a diabetic woman, indicates that the disease has not reached a critical stage. In such cases, therefore, a favorable prognosis may be given so far as immediate danger is concerned.

Intercurrent diseases during pregnancy or the puerperium possess additional gravity.

The great danger to the child's life has already been stated. Over half of the pregnancies ended in miscarriage or premature death of the child.

An important question now comes up for con-

sideration. Should a woman marry who is suffering from diabetes? From the evidence that has preceded the reply must be in the negative. The disease under favorable conditions, and with proper medicinal and dietetic treatment, holds out encouragement of a comfortable existence for several years at least. The intervention of pregnancy would remove any favorable conditions that were present, and jeopardize the expectancy of a life that at best is none too good. It is even questionable if marriage be advisable in a woman who has a strong hereditary predisposition to diabetes.

TREATMENT.—The obstetrical treatment of this subject pertains to a consideration of the advisability of the induction of premature labor. The question is entirely a new one, and we have not sufficient knowledge at hand to decide it. In the milder cases of the disease, when there is reason to think that pregnancy will terminate naturally, interference is not justifiable. But when the symptoms are acute, rapid emaciation and exhaustion of the mother threatening the existence of the child, prompt action is demanded in the interest of both. The period at which the child usually succumbs is about the seventh month; labor must, therefore, be induced at the earliest period of viability.

SUPPLEMENTAL TREATMENT OF THE PARALYSIS OF ACUTE ANTERIOR POLIOMYELITIS.[1]

BY V. P. GIBNEY, M.D.,
OF NEW YORK.

THE frequency with which cases of paralysis dependent upon poliomyelitis apply at an orthopedic hospital for treatment suggests to me the propriety of presenting to the Fellows of the American Orthopedic Association a paper on the subject of acute anterior poliomyelitis.

With the pathology and the clinical history of the affection I have on the present occasion nothing to do. I have long since become acquainted with a point in the therapeutics of this affection, a point with which all my hearers are more or less familiar. It is this: A palsied muscle or a group of palsied muscles is often very much handicapped by contractured tendons or muscles on the opposite side of the limb. Because of these contractures local treatment is often inefficient. However efficient the galvanic or the faradic current or even massage may be, if the muscle is overstretched this efficiency is certainly minimized. Another point that has forced itself upon me is this: A palsied muscle or a group of palsied muscles responds better to local treatment after a period of rest, or, at least, after being retained for a long time in normal position. These points can be illustrated better, I think, by the narration of a few cases taken at random from my notes.

CASE I.—A girl, fourteen years of age, was admitted to the hospital on January 10, 1888. The diagnosis was paralytic talipes equinus. She gave the usual history—the fever came on when she was twenty-one months of age, followed on the next morning by paralysis. She had the usual out-patient treatment. At the time of her admission, then twelve years after the date of the paralysis, the heel of her right foot was raised several inches from the floor, the toes were hyper-extended, and she bore her weight on the distal extremity of the metatarsal bones. Any attempt at dorsi-flexion of the foot caused hyper-extension of the toes, the flexion of the foot being resisted by a shortened tendo Achillis. The calf measured 10½ inches, as against 14 for the opposite side. While there was no absolute paralysis of the perineal group, there was certainly paresis, with apparent paralysis of the anterior tibial group. Two days after admission the tendo Achillis was divided, and the foot immediately flexed to a right angle, the space between the severed ends of the tendon being about 1½ inches. A convex pad was placed over this space to avoid the pressure of the bandage, the foot and leg encased in plaster-of-Paris, which was not removed until eleven days after the operation. The deformity was then over-corrected; another plaster bandage was applied, and, on the 8th of February, a steel apparatus without any joint at the ankle was used for convalescence. This enabled us to afford the palsied group of muscles rest, and on the 9th of April the girl was able voluntarily to flex the foot beyond an angle of 90°.

CASE II.—A boy, eleven years of age, presented paralysis of the right lower extremity, with anterior tibial paralysis of the left side. He was six years of age when attacked with poliomyelitis, and for at least a year after the attack was unable to stand. He moved about on crutches; finally contractures appeared, and for a year or two it was very difficult for him to walk with crutches. There was very marked lordosis, and in the dorso-lumbar region a lateral curvature to the right side; he bore his weight on the left limb, the right limb being practically a dangling leg. The anterior tibial muscles on the right side were very nearly powerless, and the quadriceps femoris was weak. The thigh-flexors on the left side, as well as the leg-flexors, were very nearly completely palsied, although the boy was able to move the knee and hip-joints with the assistance of associate muscles. The thigh-flexors, including some of the deeper fascia, were shortened, and it was impossible to extend the thigh beyond an angle of about 135°. Under ether, on the 29th of September, an open incision was made just below the anterior superior spinous process, and pretty free division of the muscles and fascia made, until the limb could be brought down to an angle of about 160°. The tendo Achillis was divided, and the leg was put up in plaster-of-Paris. On October 30th, under ether, a still further correction of the de-

[1] Read at the meeting of the American Neurological Association held in Washington, September, 1891.

formity was made, this time by manual force. On the 14th of February, 1889, the boy was discharged, able to walk without crutches, but with the limb supported at the knee by apparatus. While no electrical tests were employed in this case, it was the general impression of the hospital staff, as well as of the patient's friends, that he had much better control of his muscles than before the operation.

Case III.—The following case got about the hospital the soubriquet of the "Kangaroo Case." He was a boy, eight and a half years of age, referred to me by a distinguished orthopedic surgeon, in order that I might give him a home. A good many physicians and surgeons still hold to the idea that the hospital is a kind of a home for incurables. This boy's case seemed so interesting to me that, on November 26, 1888, I gladly admitted him to the hospital, and placed him under treatment in the wards. He presented the following history: When eighteen months of age he had "pneumonia," which lasted a month. On recovery it was found that his legs and arms were paralyzed. The arms gradually recovered power, the left leg improved a little, the right not at all. Three or four years later, he had a second attack, so the mother reports, and another attack last winter. I found his body and upper extremities well developed. He was unable to stand; the lower limbs

Fig. 1.

Representing the appearance of the boy when brought to the hospital.

were almost devoid of muscular power; what muscles remained were small and attenuated. There was slight power to move the toes of the left foot, but no such ability on the right side. The right thigh could be extended to an angle of 145°, the left to 135°. He presented a form of club-foot known as calcaneus. The internal condyles of both femoræ were were quite prominent, and there was a marked degree of genu recurvatum. I have not transcribed the comparative measurements, because they are unimportant. Under ether, on the 18th December, 1888, I made a vertical incision, one and one-half inches in length, just below each anterior superior spinous process, and while an assistant attempted to extend the thighs I divided with a scalpel and scissors (using my fingers as probes) all muscles and fascia offering resistance. I found that I came quite down to the capsular ligaments. I made counter-openings behind the major trochanters, and for drainage inserted a small strip of iodoform gauze, closing the primary incisions with catgut. By this time I was enabled to extend the thighs to an angle of 180°, bringing them down parallel, and after putting on a full antiseptic dressing I applied a plaster-of-Paris bandage extending from the axilla to the balls of the feet. By the 18th of January, the incisions had entirely healed, and without any apparatus the limbs lay parallel in bed. I soon put on a pair of long springs, without joints at the knees, but with a limited joint, that is, a small range of motion at the ankles. These springs were attached to a pelvic band. With these springs and a pair of axillary crutches the boy was soon walking about, and his appearance is shown in the accompanying photograph. He remained in the hospital until September 5, 1889, when an examination was made prior to his discharge. There was no appreciable increase in the power of the muscles

Fig 2.

Appearance of the boy as he left the hospital.

of the right lower extremity. He could move the left leg and also the foot, as well as the toes. The psoas and iliacus had evidently gained power. He has reported from time to time in the out-patient department; he attended school, and from a condition of helplessness he has become quite helpful to himself. Instead of walking like a kangaroo, he walks like a human being.

Examined September 2, 1891, he was found able to get about with the braces extending only above the knee, and with crutches. He goes to school. His

limbs are in very good position. The left thigh is extensible to an angle of 180°, the right to about 170°.

CASE IV.—A very helpless girl, cursed with an excess of adipose tissue, and only eight years of age, was admitted to the hospital January 27, 1890. Her poliomyelitis came on at two and a half years of age. This was followed by paralysis of the neck, and of the upper and lower extremities. She recovered the use of her neck and upper extremities, but her lower limbs remained more or less palsied, and the ligaments about the knee-joints became relaxed, so that when she came under hospital treatment she was very unwieldy, and was only able to balance herself on crutches. The thigh-flexors were shortened, the knees were in recurvatum and valgum, the right foot presented calcaneo-valgus, and the left foot varus. As she lay on the table for examination there was very marked lordosis of the spine—that is, when extension of the thighs was attempted. With the thighs flexed, however, this lordosis was overcome. The limit of extension of the left thigh was 140°. The right knee could be extended to an angle of 150°, the left was hyper-extended; there was very little power of flexion or of extension of the legs. There was a moderate amount of power in abduction, none in adduction, and no power of rotation. These movements pertained to the thighs. The legs and feet presented more or less paralysis in certain groups. The details are omitted as not pertinent to our subject. Suffice it to say that on February 4th she was subjected to about the same operation as in the preceding case. The left hip was found to be easily disarticulated, so that it was necessary to retain the dressings and plaster longer than is ordinarily done. By the first of April she was in a pair of long springs (without any joint at the knee) and on a pair of axillary crutches. She was discharged on the 12th of May. Recently she reported, to have her apparatus put in order, and she was found to be much more self-helpful. The mother states that the girl gets about comparatively well.

CASE V.—In March, 1889, a merchant of St. Louis brought his daughter, seven years of age, to New York in the hope of getting some relief from a paralytic deformity that made the child quite helpless. She had not stood alone or walked since she was fifteen months of age. At that time she had an attack of poliomyelitis. I found a great loss of power in the external rotators of the right limb; indeed, the paralysis was about complete. The internal rotators were also weak. The extensors of the leg were palsied, although the tensor vaginæ femoris and the sartorius seemed sufficiently strong to enable her to hold the limb extended for a minute or two. The flexors were weak, though not completely palsied. The extensors and flexors of the feet were palsied. By making a strong effort she could barely flex the toes. The flexors, especially the tensor vaginæ femoris, were shortened, so that it was impossible to extend the thighs beyond an angle of about 135°. In the left limb the gluteals were practically absent, the external rotators very feeble. The head of the femur rolled out of the acetabulum with a thud; the flexors and adductors were especially strong and shortened, preventing extension beyond 135°. The extensors of the leg were palsied, the flexors good. The gastrocnemius was weak, but the girl could flex and extend the foot fairly well, although the limb was much atrophied. I advised an operation, and on the 24th of September, 1889, the shortened tissues were divided, the limbs brought down parallel with each other, and the deformity fully corrected. There was no reaction to speak of. Within a month she was fitted with apparatus and was soon in the upright posture, walking with the aid of crutches and splints. Soon after this she returned home and became quite active. I saw her on April 8, 1890, and made a careful observation of her condition. The thighs could be extended to fully 180°. The father gave me a report of her condition last November. She was still improving in the power of the ligaments.

CASE VI.—The most extraordinary case in the way of deformity was operated upon by me in October, 1890. It was that of a boy ten years of age, palsied when eighteen months old. The paralysis affected the muscles in the loin, right side, and both lower extremities. He had an enormous curve of the spinal column to the right. The right thigh was held flexed at an angle of nearly 90°, with the head of the bone resting on the dorsum ilii. The limb could be extended to an angle of 135°, though the muscles and tissues about the front of the hip were very short. The external hamstrings on this side were quite tense, not allowing extension of the leg beyond 130°. The tendo Achillis was short; the foot was in varus. On the left side the flexors of the thigh were shortened, but not to such an extent as those on the right side. The hamstrings were also shortened to a moderate degree; the tendo

FIG. 3.

Appearance before coming under treatment.

Achillis was shortened. The thighs were much atrophied. (See Fig. 3.) I made an examination in my office and sent the boy to the hospital for operation. The impression made on my mind as he walked up the avenue on his crutches, with his right limb flexed, abducted, and rotated outward, was very painful. I wondered to myself if anything could be done to put that boy in better shape. By dividing the shortened tissues, pulling the limbs down into the best possible position, at the same time correcting the lateral curvature by manual force, I was enabled to hold him in plaster-of-Paris for several weeks. Then he was fitted with apparatus, put on crutches, and the result has been most gratifying. He walks erect, his limbs are parallel, he is growing, and his spinal deformity, which seemed to me almost hopeless, has improved at least 50 per cent.

I am aware that these case are incomplete from a strictly scientific point of view. I would hesitate to present them to a neurologist without a record of the electrical examination, the actual power (as measured by the dynamometer) remaining in the different groups of muscles, and also a record of these two points subsequent to the operation. Many years ago I reported my cases in this way, but of late years I confess that my examinations electrically have not been so precise. All I advocate is the correction of deformity, the removal of tension from a weakened muscle, the replacement of the joint-surfaces in normal apposition, and the assistance generally given to a limb the muscles of which are weak and palsied. In a number of cases I have been fortunate enough to secure the assistance of a neurologist, I first supplementing his work, he subsequently supplementing mine.

This crude paper is presented to the members of this Association merely as a contribution to the management of a very difficult class of cases—cases before which the neurologica heart often recoils.

THE PRE-TUBERCULOUS CONDITION.[1]

By J. HILGARD TYNDALE, M.D.,
of New York.

Consumptives may be divided into three classes:

1. Those with infiltration caused by mechanical pressure—the result of fixed pleuritic adhesions on the one hand, and on the other of connective-tissue proliferation and contraction in the lung itself—so-called chronic peribronchitis.

2. Those with infiltration as a remnant of acute disease, or with tuberculosis as yet strictly *localized*, the bacillus having forced an entrance into non-resisting cells.

3. Those with more or less rapidly diffusing tuberculosis, *preceded* by a lowering of the general condition.

The first two start with *local* conditions at a time when there is a good, or a fair, general condition. The third class takes its starting-point from an *impaired general condition*, and it is of this I wish to speak.

I hold it as a maxim that *localized* tuberculosis does not of itself endanger life, so long as the general nutrition begets a *reasonable resisting power of the lung tissues*. Hence when the starting-point is an impoverished nutrition, we are dealing with the true pre-tuberculous condition.

My starting-point is, therefore, *general malaise*, as yet unaccompanied by any physical signs in the lungs, not even by modifications in rhythm or pitch of breathing. I will not dwell upon predisposition or acquisition any more than to say: Beginning with fetal life, colinization of the bacillus in early life is favored by:

1. Transmission with the ovum, kept in latent abeyance.

2. Inherent inability, in bodies built after the type of phthisical habitus, of the leucocytes to digest the bacillus tuberculosis.

Acquisition of the bacillus in later life is in the apparently healthy favored by:

1. Insufficiency in anatomical development of the thorax.

2. Insufficiency in physiological expansion, as *e.g.*, in the ossification of the cartilages. These two conditions of lessened mobility of the chest and a consequent stagnation of air, is shown in a tendency of the *upper* lobes to tubercular invasion.

3. Parts of lung being confined by pleuritic adhesions and thus affording facility for a prolonged lodgment of the bacilli—these receiving both board and lodging for a term sufficient for their development. This is especially true of the *lower* lobes.

From the above causal elements I now coin this general maxim: *Constructive or destructive metabolism is inherent in the person.*

Now as to the true pre-tuberculous condition, both in the constructives and the destructives, let me first clear my path of obstructions by excluding considerations of age, sex, or race; influences of previous general disease (typhoid fever); or of still present general trouble (syphilis, diabetes); also remnants of acute lung disease; suppurating wounds or other septic sources within the body; and cheesy glands in the neck or axilla,—as sources of *direct* infection. All these are centers of infection from demonstrable local sources.

Excluding thus all general and local disease enumerated above, we see our way clear to a conception of the true pre-tuberculous condition. We are consulted by a person that complains first and foremost

[1] Read before the American Climatological Association at Washington, D. C., September 25, 1891.

of *general malaise*. This general malaise is readily shown to be composed of partial failure of several or of all functions of the body; inability to exercise the motive power; muscular debility known as feeling "sawed-off in the legs;" sensation either more acute or dulled; sleep either fitful or too profound—always extremes; variable digestive capacity; superficial breathing; and last, but not least, a rapid heart-action. In other words, there is a falling off in the daily routine of eating, breathing, elasticity in walking, refreshing sleep, a buoyant mind, to which is added vague disturbances of sensation. As yet there is no elevation of temperature. This is the rough picture of the *general* condition—by inclusion, if I may so call it. By exclusion, you will now find *acute* diseases (typhoid fever, for example) absent; likewise *chronic* ones—of which diabetes may serve as an example.

Approaching the local condition we find that, *as yet*, inspection, auscultation, and percussion furnish no clue whatever, not only as to dry and moist râles, but even as to changes in the respiratory elements of quality, pitch, or even of rhythm. This leads us to our second maxim: All more than temporary departures from well-being, of which the patient has been conscious for weeks or perhaps even months, and which by careful diagnosis cannot be made to fit into the frame of a recognized trouble, acute or chronic, functional or organic, represent the true pre-tuberculous condition. Correct appreciation of the pre-tuberculous condition can only be reached by exclusion.

Nothing now remains except to sharply outline the exact sequence of events in the pre-tuberculous condition, and in order to make the picture as clear and as distinct as possible, I shall divide the events into stations. Please bear in mind that I aim to give, in a few words, the whole course of the pre-tuberculous disease from beginning to end, and desire this to be remembered: The first station is entirely made up of *subjective* symptoms, and represents the true pre-tuberculous condition. The second and third stations are made up of the same subjective malaise, *plus* the objective findings in the lungs—and these merge into well-known types of tuberculous invasion.

Station First (*subjective*). General malaise, not fitting into the frame of recognized acute or chronic disease—in this respect comparable to neurasthenia, which is also diagnosticated by exclusion. As stated above, "general malaise" is a falling off from the individual norm of eating, breathing, muscular power, refreshing sleep, buoyant mind, etc. This impaired *general* condition leads up to the *local* lesion, both subsequently uniting to bring about destruction.

Station Second. This consists in the above subjective symptoms *plus* the objective change in the character of the respiratory elements, but as yet without râles, either dry or moist. The general condition advances to noticeable loss of adipose tissue in some, or, in others, of red blood-corpuscles, up to the verge of pernicious anemia—or to both combined. The order of importance in respiratory changes is, in auscultation: quality, pitch, and rhythm. The changes now occurring are in the reverse order of their importance: rhythm first, then pitch, then quality. This is the main point I wish to emphasize. As to *rhythm:* Interrupted (cog-wheel) inspiration (a pause not existing in the norm), a prolonged and audible expiration. As to *pitch:* Higher than the original vesicular low pitch. This holds good of both auscultation and percussion, and is in accord with Dr. Leaming's great law: Low pitch denotes porosity, high pitch denotes density. As to *quality:* From vesicular to broncho-vesicular, and finally bronchial, or, as I prefer to call it, tubular.

Station Third. Dry, followed by moist râles and gurgles, according as the tuberculous invasion begets a localized or a widespread bronchiolitis or local excavation. The third station of pre-tuberculous patients is, therefore, either a direct rush into diffused tuberculosis (general bronchiolitis, or tuberculous pleurisy) in those of destructive metabolism; or, in those of constructive metabolism, a more gradual destruction by infiltration and excavation, perhaps with subsequent limitation.

In conclusion, I offer the following maxim: The pre-tuberculous condition is a tuberculous invasion as yet undemonstrable, engrafted upon those whose nutritive changes have brought them to a condition below par as compared with their usual physiological condition. This physiological unit is strictly and absolutely individual.

INHERITED SYPHILIS OF THE LARYNX.

BY S. G. DABNEY, M.D.,

CLINICAL LECTURER ON DISEASES OF THE EYE, EAR, AND THROAT, AT THE HOSPITAL OF THE COLLEGE OF MEDICINE; VISITING SURGEON TO EYE, EAR, AND THROAT DEPARTMENT, LOUISVILLE CITY HOSPITAL, LOUISVILLE, KY.

THOUGH much has been written on the subject of laryngeal disease due to acquired syphilis, we find in the text-books but little descriptive of the inherited form of syphilis manifesting itself in the larynx. Thus Mackenzie says: "Hereditary syphilis (of the larynx) is occasionally met with in children, though I have never seen a case in a child younger than seven years. In each of the five examples I have met with there was ulceration of the edge of the epiglottis, with exposure of the cartilage." Lennox Browne is of the opinion that "as a rule the ulceration of congenital syphilis is limited to the palato-pharyngeal and naso-pharyngeal tissues,

and that laryngeal mischief is a comparatively rare sequel." The following cases, therefore, seem worthy of report as illustrating hereditary syphilis of the larynx, and perhaps as possessing some points of interest in themselves:

Case I.—Miss B., aged sixteen, consulted me in November, 1890. The medical history given by her mother was as follows: The patient was the oldest of five children, all of whom had been fairly healthy. In November, 1889, she had diphtheria, several other children in the neighborhood being affected at the same time. For this she was attended by my friend Dr. A., who corroborates this part of her story. After recovery her throat remained weak, and in the spring of 1890 it gradually became much worse. From that time until her visit to me her symptoms had gradually increased in intensity, although she had during this time been treated by three physicians.

On examination I found the patient to be marked by the doughy skin, facial cicatrices, and peg-shaped, notched, upper incisor teeth, described by Jonathan Hutchinson. Her voice was so rough and hoarse and low, that it was difficult to understand what she said. She suffered no pain, but had great discomfort in swallowing, and even in speaking. Her mother said that her breathing when asleep was noisy and difficult. Examination of the nose showed only some hypertrophy over the turbinated bones. The uvula was long and club-shaped, and quite deeply ulcerated on its lower posterior surface. The laryngoscope showed the epiglottis to be eaten away in perhaps one-fourth of its extent, the ulceration having proceeded from the edge. What remained was much thickened and of nodular surface, somewhat resembling lupus. The ary-epiglottic folds were also thickened, and on and above the ventricular band of each side was deep ulceration. It was impossible at this time to see the cords.

The diagnosis lay between tuberculosis and syphilis, acquired or inherited. Careful examination gave no evidence in favor of phthisis, and absolutely no history in any way suggestive of acquired syphilis could be obtained. The age and social standing of the patient, and the character of the lesions, which could only be tertiary if acquired syphilis produced them, made this supposition altogether unlikely, though of course not impossible. I was thus led to regard the case as one of inherited syphilis attacking that part whose power of resistance had been lately lessened by diphtheria. This tendency of hereditary disease to invade a weakened organ is well known.

Dr. Adolf Bronner, at a meeting of the British Ophthalmological Society, lately called attention to the appearance of congenital syphilis in injured eyes. In the case just related rapid improvement took place under the daily administration of sixty grains of iodide of potash and one-sixth grain bichloride of mercury, together with the use of detergent sprays and nitrate of silver locally.

Case II.—Miss B., aged seventeen. Her father and mother died when she was five years old. Their medical history is unknown. She has one brother, two years her senior, and reported healthy. Miss B. became almost absolutely deaf at fourteen years of age, the deafness being permanent, unattended by pain, and attaining its maximum in about three months. At the same time she suffered from diffuse inflammation of each cornea, whose traces as well-marked opacities are still visible. She came to see me on account of her throat. I found a long perforation in the anterior faucial pillar of the right side, deep and ragged ulceration of the pharynx, and one large irregular ulcer on the right ventricular band of the larynx. Here the diagnosis was unmistakable. Appropriate treatment was followed by speedy improvement.

CLINICAL MEMORANDA.

CASE OF COMPARATIVELY LATENT AND QUICKLY ENDING DIABETES AFTER INFLUENZA.

By M. MAGELSON, A.M., M.D.,
of Fergus Falls, Minn.

Mr. K. F. L., a farmer, thirty-three years old, sought my advice on the 26th of June, saying that he had previously enjoyed good health; until the beginning of last April he had pains in the back of his head, with sneezing, soreness of the eyes, lancinating pains in the arms and legs, fever and a feeling of general weakness. In fourteen days this attack left him, and he was then very weak, had considerable cough, lost his appetite and ran down in flesh. He spat some blood one week in May, and sought medical advice on account of his lungs. He grew weaker, the cough got more and more annoying, and he raised more and more of a thick greenish expectoration. In the middle of May he had some night-sweats. Examination showed a chronic bronchitis in both lungs. He complained of weakness, loss of appetite and a steady cough that disturbed his sleep. His tongue was markedly dry, and this, as well as the upper part of his throat, had a glazed appearance. He was not very thirsty, and did not pass his water frequently, and it is especially to be noted that he did not have to pass it in the night. There were no symptoms of itching or impairment of sight, no odor from his skin or breath, and no sweating. His bowels moved regularly every day. His urine was clear in color, reddish yellow, and had a specific gravity of 1042. The amount passed in twenty-four hours was 1760 c.c. By approximate valuation of the amount of Fehling's test solution, the percentage of sugar was estimated as between 20 and 25 per cent. As the amount seemed to me to be extraordinary, two drops of the urine were evaporated at common summer temperature upon an ordinary glass slide, and photographs made of the sugar deposit in each drop magnified 22.5 diameters. I will remark that the height of the deposit was fully proportioned to the extension. He stayed a week under a treatment of opium and Carlsbad Sprudelwasser. The cough stopped and he slept well, but there was no lessening of the amount of sugar in the urine. On the 30th of June he went home to Dakota, about seventy miles

from me, as I had told him that I thought his disease was incurable. On the 3d of July he died. From the description that his wife gave me in a letter, I think he died in diabetic coma. The case is interesting from the facts of its short duration, its comparative want of symptoms, and as a direct result of a rather moderate attack of influenza. Because I did not have sufficient time to make exact and repeated quantitative analysis of the amount of sugar, I will not discuss the amount but only say that I was convinced that it was surely 25 per cent.—larger, indeed, than in that of any other case that I have seen reported.

STEEL IN THE IRIS FOR TWENTY-SEVEN YEARS.

BY F. C. HEATH, A.M., M.D.,
OCULIST TO ST. ELIZABETH'S HOSPITAL, LAFAYETTE, IND.

SOME time in 1864, Mr. P. E. H. was engaged in reaming a tire on a locomotive engine, when a small piece of steel, about two mm. long, from the reamer, penetrated the cornea of his right eye, lodging in the iris, about midway between the pupil and the outer margin. In about four weeks the "irritation" fully subsided. It gave no further trouble until five years ago, when inflammation arose, as he thought, from irritation of the eye by gravel. This quieted down after a week's treatment by Dr. J. L. Thompson, of Indianapolis.

The patient came to me in June last with a well-marked iritis that had started five days before. He again made a good recovery, under two weeks' treatment with atropine, leeching, etc., and the eye has been free from pain, ciliary injection, or other symptoms of iritis ever since. The vision is unaffected.

It is exceptional for a foreign body to remain so long in the iris and produce so little trouble. Noyes mentions a similar case of *nineteen* years' duration, but this is *twenty-seven*.

BLACK STAINING OF DIAPERS FROM THE USE OF SALOL.

BY S. RUSH KETCHAM, M.D.,
OF PHILADELPHIA.

IT has been my custom to use salol considerably in diarrheal diseases of children, and in the case of a child six months of age I used two-grain doses three times daily. In about forty-eight hours the mother was greatly excited, and told me her child was passing blood in the urine. I immediately called for the diapers, and finding numerous stains of a dark-pink and black color, I concluded that they positively were not blood-stains, but that they were produced by carbolic acid, as salol is chemically a salicylate of phenol. No other symptoms were present, and, after ceasing its administration, the staining of the diapers disappeared in twenty-four hours.

MEDICAL PROGRESS.

Esophagotomy.—KRÖNLEIN (*Corresp.-bl. für Schweizer Aerzte*, August 15, 1891) presented to the Society of Physicians of Zurich the case of a man, fifty years old, who swallowed a bone, which became impacted in the esophagus. Subsequently the stools were bloody and the man became anemic. Attempts to remove the obstruction failed. Twelve days after the accident, esophagotomy was performed. The only complication encountered was hemorrhage from the eroded superior thyroid artery, which was readily controlled. The sharp-cornered foreign body was removed. The wound of the operation healed satisfactorily, but exhausting hemorrhages took place. Nevertheless, complete recovery ensued in the course of six weeks, the patient, however, being still anemic. Krönlein took occasion to state that he had already performed esophagotomy for foreign bodies in four cases.

Traumatic Communication of Carotid Artery and Cavernous Sinus.—WHERRY (*Lancet*, August 29, 1891) reports the case of a lad, thirteen years old, who, after a traumatism, presented the symptoms of concussion of the brain. Double ptosis, with dilatation of the pupils, developed. Three weeks after the injury, the boy was seized with tetanic spasm of the head and neck. On the day following, the eyelids were edematous, with proptosis of the left eye. Under energetic treatment some improvement took place. At the end of another three weeks there occurred an attack of severe pain in the left orbit, with increased proptosis. An incision disclosed an extravasation of blood in the cellular tissue of the left upper lid, with distinct pulsation. On auscultation of the forehead, a loud bruit was detected. The sound was continuous, but was reinforced with the pulse, and could be obliterated by compression of the left carotid artery. On ophthalmoscopic examination, evidences of double optic neuritis were found. It was held that the base of the skull had been fractured and a communication established between the carotid artery and the cavernous sinus. A certain degree of improvement took place, but ultimately it was determined to ligate the left common carotid artery. This was accordingly done. The bruit at once ceased, but alarming symptoms developed. For a month there was coma, with dysphagia, incontinence of urine and feces, paralysis and rigidity, but recovery ultimately took place.

Gumma of the Retina.—LEWIN (*Berl. klin. Wochenschrift*, July 13, 1891) presented to the Dermatological Society of Berlin the case of a man twenty-six years old, in which, thirty days following infection and two weeks after the development of a chancre, an echthymatous eruption, drying into black crusts, appeared all over the body and face. At the same time retinitis pigmentosa was detected, as well as a bean-sized prominence in the lower left quadrant of the retina, which it was concluded was a gumma. Obstinate at first, the condition gradually yielded to subcutaneous injections of iodide of mercury.

Treatment of Hyperidrosis.—In the *Revue Général de Clinique et de Thérapeutique*, the following prescription for sweating of the hands and feet is given. The application is to be made night and morning. The part is first washed with hot water and immediately afterward the following ointment is applied:

℞.—Ichthyol . . . . . 1 ounce.
Vaselin . . . . . 1½ ounces.

The Medical News.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to The Medical News will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment. When necessary to elucidate the text, illustrations will be provided without cost to the author.

Address the Editor: GEO. M. GOULD, M.D.,
1004 Walnut Street,
Philadelphia.

Subscription Price, Including Postage in North America.

Per Annum, in Advance . . . . . $4.00.
Single Copies . . . . . 10 cents.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
Nos. 706 & 708 Sansom Street,
Philadelphia.

SATURDAY, OCTOBER 10, 1891.

THE THERAPEUTIC VALUE OF HYPNOTISM.

Several important books upon Hypnotism have appeared during the current year in France and Germany, and the question of its therapeutic value cannot be considered as settled. All, however, agree that the method has great dangers if its unrestricted practice be allowed, and that the eye of the law must be kept sharply on the watch to guard against easy abuse and invited danger. Preyer's book (*Der Hypnotismus*, etc.) of 217 pages accepts almost none of the modern additions and claims; it rests essentially upon the development of the "science" as given by the older masters, Braid, Heidenheim, Charcot, etc. Bernheim's 500-page octavo (*Hypnotisme, Suggestion, Psycho-thérapie : études nouvelles*) is the completest and latest exposition of the leader of the Nancy school. The volume is largely devoted to the clinical histories of cases in which, according to the author, hypnotic suggestion has been able to effect cures in a multitude of cases of multiform nervous disease. Wetterstrand of Stockholm (*Der Hypnotismus und seine Anwendung in der praktischen Medicin*, 122 pages), is also an enthusiastic believer in the power of suggestion to cure disease. He has had an immense clinical experience—over 3000 cases. He describes in detail and with perfect sincerity the histories of cures of rheumatic disease, epilepsy, morphinomania, and many other types. Ringier's volume of 200 pages has a double interest, in that the author is a country practitioner and that he is a conscientious and earnest character, carefully trying to get at the truth of the value of suggestion-therapeutics. He subjects his 210 cases to careful scrutiny and gives as close an analysis of his failures as of his successes. He divides his cases into seven groups: 1. Those neuroses pertaining to the motor, vasomotor, or secretory systems; 2. Neuroses of the emotions, or neuralgias; 3. Insomnia; 4. General cerebral neuroses or psychoses; 5. Rheumatic affections; 6. Intoxications; 7. Sundry affections. Liebeault's *Thérapeutique Suggestive* (300 pages) will have especial interest for students of animal magnetism. He frankly confesses that his former experiments of this kind upon children have proved mere illustrations of suggestion-hypnotism. There is also a free confession of many injuries to patients committed by him in hypnotic experiments.

Those interested in the question of the influence of drugs upon the suggestibility of the patient, especially its increase by cannabis, may consult Schrenk-Notzing's *Die Bedeutung narcotischer Mitteln für den Hypnotismus*. The psychological aspects of hypnotism are especially treated in Janet's *l'Automatisme psychologique* and Dessoir's *Experiment. Pathopsychologie* (*Vierteljahrsschrift für wissensch. Philos.*, Jan. 15, 1891).

A thoughtful and conservative practitioner, Dr. Eskridge, delivered an excellent address upon this subject before the Colorado State Medical Society, which is published in the *New York Medical Journal*, August 1, 1891. The whole subject is reviewed in the light of a not inconsiderable personal experience. The value of hypnotism as a therapeutic agent is found to depend upon mental impression and the permanency of the same. No mysterious influence other than this is exerted over the subject, and the state of hypnosis, so far as the physician is concerned, is simply a condition of greater sensibility to impressions. Indeed, repeated impression without the abnormal suggestibility of hypnosis is often quite as effective. Dr. Eskridge rightly emphasizes the dangers of hypnotic practice in the hands of the ignorant or incompetent, and strongly urges the legal restriction of licenses to physicians and scientific investigators.

It remains an open question whether the unpre-

ventable dangers of hypnotic practice will be found to outweigh the therapeutic use and value. The domination of a weak will by a strong one, the control of attention either by another's or by one's own will, the direction of emotion by effort and resolve—these are the commonest facts of every-day life. It would seem that much of the philosophy and mystery of hypnotism come down to this simple explanation: viz., that it consists in renunciation of self-control and in heightening and emphasizing the power of the attention, and in fixing the will-less mind in determinative control of in-coming sensation and out-going innervation. When the attention is absorbed by one thought or act or sensation, others that come to the consciousness are unnoticed. Again, when the will is absorbed in one act, another may be carried out without consciousness. These are normal, every-day facts; hypnosis simply morbidizes the condition. It is usually only diseased and weathercock wills that the breezes of external suggestion can blow hither and thither, and though such wills are sad enough and common enough facts, the ideal of true character must consist in self-control and autocracy. Consequently the physician that uses hypnotic suggestion or plain common-sense advice and encouragement, must do it with the distinct object of righting the diseased will and strengthening it in self-control. It can hardly be doubted that the hypnotizing therapeutists have often been more occupied with the psychology than with the cure, and that the education of the patient's self-control has not always been a primary object. Hysterical condition has been produced in order to cure hysteria, and neurosis *b* has replaced neurosis *a*. If human vivisection, practised with the clearest and most earnest desire to thereby further human weal, is squarely criminal, it may be conceded that to play and juggle with the profoundest mysteries of neurological and psychic life is the most wanton cruelty. About the inter-relations of will and sensation, mind and body, consciousness and nerve-centers, we know quite as much as a Hottentot savage would know about the use of the instruments at the Lick Observatory. The tricks of the hypnotist with the enslaved consciousness remind one of what the savage might do among the telescopes. We must have a better psychology and an infinitely more perfect pathology and pathogeny of psychic disease, before we shall be capable of intelligent use of hypnotic control and suggestion as justifiable methods of cure. Let us make haste very, very slowly.

EMPLOYMENT OF INSANE IN THE EASTERN MICHICAN ASYLUM AT PONTIAC.

IT gives us pleasure to excerpt the following from the biennial report of the Medical Superintendent of this institution:

"The policy long ago inaugurated and carried into execution in respect to employment of patients has been continued and extended on certain lines. In addition to the employment of male patients in the care of stock, upon the farm, in the shops, and in working-parties of the more trustworthy, under the direction of an out-door attendant, the plan has been adopted of sending out, in rotation, parties from each of the 'disturbed' halls in the male department, once a week in the summer season, to do odd tasks of weeding, raking, grading, wheeling cinders, road-making, and similar light work. This exercise has taken the place of the purposeless walk, and has been found to operate favorably in promoting the quiet and comfort of the halls and the welfare of patients as well as beautifying and adorning the Asylum premises. Under this system it is practicable to give employment to nearly all male patients who are physically able to undertake work out of doors. The enlargement of the kitchen has afforded additional room for the employment of patients in this department, and the increased numbers under treatment have rendered it necessary that this help should be supplied to the kitchen. For female patients an ironing-room has been fitted up at the laundry, and parties from the different halls assist regularly in ironing. The substitution of gas heaters for the large stove formerly in use for heating flats, has economized the time of employés and patients, and has rendered the accomplishment of laundry work less difficult. It has been found practicable also to employ in connection with the wash-room in the laundry several female patients of vigorous constitution.

"These additional opportunities for employing patients have been of the utmost value in treatment, and their importance cannot well be over-estimated. It is contemplated during the coming biennial period to introduce broom- and brush-making, and thereby furnish in-door employment to certain male patients in unpleasant weather.

"On the day that this is written, there are actually employed out of doors and in different outside departments of the Institution 248, out of a total of 518, male patients, and this is in addition to those regularly employed in in-door occupations and hall work."

AN ERA OF PREVENTIVE MEDICINE.

THE world is progressing. It is not sufficient to be provided with remedies for correcting existing

evils; the demand of the hour is for means that will prevent their occurrence. As our knowledge of disease grows, not only are we better fortified to combat it, but we are also placed in a position in which we can obviate its development or extension. It is especially the etiology of disease from which we can hope to learn the prophylaxis. An era of preventive medicine has set in—not with any abruptness, it is true, for the prophylaxis of disease is as old as medical practice itself, of which it forms but a part; but the subjects of hygiene and sanitation and vital statistics have become matters of popular education.

As we learn more of disease, and as the superstitions surrounding it and its therapeutics are dispelled, the conviction becomes stronger that with some notable exceptions we can do little to overcome the disease-process. The most we can hope for is to assist and encourage Nature in her efforts to bring about recovery, removing complications and meeting emergencies as they arise. It thus becomes quite as important to know when to abstain as when to interfere.

What has been said in the foregoing is borne out by the proceedings of the Seventh International Congress of Hygiene and Demography recently held at London. The meeting occupied an entire week, was patronized by the highest authorities of England, and was participated in by some of the most brilliant minds, both lay and medical, of many countries. A glance at the work of the Congress, but a brief summary of which we have been able to present, will show how far-reaching were the subjects discussed, of which a pleasing feature is that they deal not only with disease and causes of disease, but with the relations of these and of environment and occupation to individuals and to communities. They enter into the very lives of the people. The hope is justified that much good may result from the deliberations of a body so strong, both intellectually and politically, as was this last Congress. While there may be a want of unanimity of opinion as to the immediate causes of disease, there is less diversity as to the general measures to be adopted to prevent its spread.

THE QUACK AND THE POSTMASTER.

We have received copies of circulars presumably sent to all the postmasters of this country, in which extraordinary inducements are offered them in order to secure, by their aid, lists of persons that receive their mail at a specified office. The lists are to be of two kinds: all those not invalids, and those that are suffering from any chronic ailment. The postmaster is especially instructed to give "the names of persons suffering from rupture (breach), for which we possess a new and radical means of cure; also, those suffering from piles, or from fistula-in-ano, for both of which diseases we have new, improved, and radical methods of treatment, or of those afflicted with diseases of the throat and chest; or of the digestive organs, heart diseases, diseases peculiar to women, scrofulous diseases, as fever-sores, white swellings, and old sores or ulcers; also, the names of any sufferers from diseases of the urinary organs, as diabetes, Bright's disease, gravel, inflammation of the bladder, stone in the bladder, strictures, and kindred affections; or from epilepsy, or fits, chorea or St. Vitus's dance, paralysis, curvature of the spine, nervous debility, or from tumors, or any other chronic diseases, for all of which our Institution offers special advantages and facilities for treatment. Please to be particular to indicate opposite every name, 'in the Invalids' division of the list,' the disease (if known to you) with which the party [*sic!*] is supposed to be afflicted."

Upon the receipt of the list the presumption is that the people will be deluged with testimonials and promises to cure, from the proprietors of the "Cosmic Dispensary and World's Therapeutic Institute."

The only law or ruling pertaining to this abuse of the United States Postoffice for the purpose of preying upon the gullible, is contained in the following Postoffice order: "Complaints having been made to this Department that the names of persons within the delivery of postoffices are frequently furnished by postmasters upon the application of parties desiring to mail to the addresses so furnished improper matter, covering, in many cases, indelicate advertisements or cunningly devised schemes to defraud, postmasters are hereby forbidden, in any case, to furnish such lists, until they are satisfied the parties making the application will not use the names for improper purposes, and reasonable assurance has been given that such lists will not be offered for sale or transfer."

It would appear that this lax instruction is not by any means sufficiently explicit and inhibitory. The execrable business should not be thus even indirectly aided by the General Government. The physicians of each village and town should see that the postmaster does not thus disgrace his office.

EDITORIAL INDEPENDENCE.

WE trust that no reader of THE NEWS will fail to reflect upon the striking condition of medical journalism, at least in one instance, illustrated by the incident related in DR. DILLER'S letter, published in another column of the current issue of THE NEWS. It remains wholly within the power of the conscientious physicians of this country to determine whether their professional journals shall be solely devoted to unbiassed medical truth and science, or whether these journals shall be the hypocritical mouthpieces of concealed control or of financial scheming. What a shame that the editor in question did not at once resign rather than write that second letter!

SOCIETY PROCEEDINGS.

AMERICAN NEUROLOGICAL ASSOCIATION.

Seventeenth Annual Meeting, held at Washington, September 22, 23, and 24, 1891.

FIRST DAY—SEPTEMBER 22D.

DR. WHARTON SINKLER, of Philadelphia, delivered the President's Address. He recommended that an effort be made each year to obtain papers from some of the foreign honorary and associate members. He announced that since the preceding annual meeting twelve books and one hundred and seventy-seven papers had been published by Fellows of the Association.

Dr. Sinkler reported "A Case of Acute Spinal Paralysis; Death on the Twelfth Day; Autopsy Showing Transverse Cervical Myelitis, with a Report of the Microscopical Examination by Dr. C. W. Burr." The full text of the paper is to appear in a subsequent number of THE MEDICAL NEWS.

DR. W. C. KRAUSS, of Buffalo, read a paper on "Poliomyelitis Acuta Adultorum," in which he reported a case in a man, forty-three years of age, previously strong and healthy and with a good antecedent history. Two of the grandparents had severe attacks of measles between thirty-five and forty years of age. The father also had a severe attack of measles at thirty-four. Some members of the family displayed evidences of insanity. The patient had a severe attack of measles when thirty-eight, from which he failed to recover perfectly. At forty he was seized with fever and pain in the neck, extending down the spine. Subsequently paralysis of the trunk and extremities developed, without apparent sensory disturbance. Some improvement took place in the course of the subsequent three or four weeks. Nine months after the onset of the attack, however, the four extremities were still palsied, with atrophy, cyanosis, and edema, and with loss of faradic irritability. The reflexes were wanting; some power in the back had been regained. Dr. Krauss was unwilling to admit that the attack of measles was sufficient to precipitate a profound spinal lesion, but believed that when a neuropathic or psychopathic heredity existed, any infectious disease may induce derangement of the nervous system. In the case reported, little or no improvement followed the subsidence of the general symptoms.

DR. CHARLES K. MILLS, of Philadelphia, stated that the association of poliomyelitis and multiple neuritis is comparatively common. He related a case occurring in a child, seven years of age, in which an attack of diphtheria was followed by peripheral pains and paralysis of a group of muscles in one leg. The question of infectious diseases causing multiple neuritis in association with poliomyelitis is an interesting one. Such a result is more likely to be brought about by various toxic agents. In one case under the observation of Dr. Mills the paralysis was general, but recovery took place. There was probably an association of both lesions. Years ago Dr. Mills had directed attention to this concurrence, particularly in arsenical poisoning.

DR. ROBERT T. EDES, of Washington, thought that this concurrence might also result from the action of alcohol.

DR. G. L. WALTON, of Boston, referred to a case of multiple neuritis dependent upon lead-poisoning, with atrophy, ataxia, etc., in which death took place after spinal symptoms and cystitis. Owing to their coexistence, absolute differentiation of spinal and periphera lesions is sometimes unnecessary.

DR. C. L. DANA, of New York, stated that in all cases of acute or subacute neuritis from alcohol, rheumatism, etc., the lesion is confined almost exclusively to the peripheral nerves. He has numerous specimens to substantiate this view, in connection with the clinical histories. The condition in chronic neuritis is not so certain.

DR. G. L. WALTON, of Boston, reported "A Typical Case of Thomsen's Disease." W. C., twenty-nine years old, a printer, had suffered since boyhood from difficulty in using his muscles after a period of rest. As a child he was clumsy, and often stumbled. The trouble reached its maximum at fifteen, and has since remained stationary. Practically, all the muscles are affected, including those of the eyelids and of deglutition. The patient starts with a slow, waddling gait, but soon walks rapidly and without fatigue. Strength is preserved and the muscles are very large (according to a photograph shown). A moderate faradic current develops tonus. No other member of the family is affected in this way, but the father is said, during early manhood, to have presented a mild degree of a similar disorder. The differential features between this affection and the congenital paramyotonia of Eulenburg were shown by a case of the latter affection in a man of sixty-seven years, characterized by tonic spasm and weakness, lasting for from fifteen to thirty minutes, brought on by exercise and disappearing after several recurrences, when the exercise was continued. The affection had been observed from infancy. A brother and daughter of the patient suffered from the same disorder.

The two diseases are analogous, each depending upon a congenital defect in the muscular apparatus, perhaps also in the central nervous system, the difference consisting in the mode of onset of the increased muscular irritability.

DR. C. H. HUGHES, of St. Louis, maintained that

Thomsen's disease is an affection of the muscular system, and doubted the entity of the disorder, considering it symptomatic.

Dr. Philip Coombs Knapp, of Boston, read a paper on "Astasia-Abasia," which he defined, after Blocq, as a morbid state in which the impossibility of standing erect and walking normally is in contrast with the integrity of sensibility, of the muscular strength, and of the coördination of the other movements of the lower extremities. Dr. Knapp had collected forty-nine cases from various sources, and reported a case under his own observation. The patient was a male, fifty-eight years of age. When recumbent, movements were fairly vigorous. Sudden spasm, with rigidity of the extremities, occurred. Subsequently retropulsion, difficulty in articulation, and involuntary movements developed. Tonic treatment was inefficacious. The best results have been obtained by moral treatment and the substitution of volitional for automatic movements. The condition cannot be considered a morbid entity, but a complex of symptoms.

Dr. G. M. Hammond, of New York, maintained that the affection is not organic, because the movements of walking could be performed when the patient was recumbent. He considers the affection a manifestation of hysteria. He had found bicycle-riding a most useful remedy.

Dr. C. L. Dana, of New York, corroborated Dr. Knapp's suspicion of the case as one of paralysis agitans. He had a patient presenting astasia-abasia, with manifest paralysis agitans.

Second Day—September 23d.

Dr. Morton Prince, of Boston, read a paper on "The Pathology of Hysterical Anesthesia," illustrated by two cases showing some unusual phenomena. In the cases demonstrated, notwithstanding the existence of deep anesthesia, impressions upon the hand were felt. Pinching and pricking were not recognized. When the subjects were hypnotized, they accurately described the tests that had been applied to the anesthetic parts, of which they had not been conscious. The impression was thus felt, but not perceived. The most probable explanation is that the middle sensory centers of Hughlings Jackson were normal, but that the highest centers, in which impressions are coördinated with the other psychic states constituting consciousness, were inhibited.

A paper on "A Case of Tumor of the Cerebellum, in which Trephining was Done for the Relief of Pressure," by Dr. Philip Coombs Knapp and Dr. E. H. Bradford, of Boston, was read. The report was of a man, twenty-eight years old, with a negative family history, who had poliomyelitis when seven months old. When twenty-six, severe right occipital headache developed, with diplopia, impairment of vision, double optic neuritis, convulsive attacks and nausea and vomiting. Ultimately vision was entirely lost, as well as the sense of smell. Large doses of iodides accomplished no improvement. Hearing was lost; difficulty in deglutition and in articulation developed. The mental condition remained unaltered. A trephining operation in the right temporal region over the Sylvian fissure was followed by relief of the pain. Hernia cerebri developed and death took place two months after the operation. At the autopsy a tuberculoma was found in the left lobe of the cerebellum.

A paper, entitled "A Case of Trephining and Excision of the Cortex for Jacksonian Epilepsy," by Dr. W. W. Keen and Dr. Charles K. Mills, of Philadelphia, was next read. The case reported occurred in an adult who, ten years previously, presented left hemi-paresthesia, to which, five years later, left hemi-spasm, without loss of consciousness, was added.

Dr. Keen trephined over the motor cortex and removed the centers for the shoulder and the upper arm. There were found thickening and sclerosis of the bone and a small growth over the dura, which, upon microscopical examination, proved to be a sarcoma. Three days after the operation, there was paralysis of the arm and leg, but by the thirtieth day power had completely returned. No sensory symptoms developed. During eight weeks after the operation convulsions occurred, but they were of milder character than they had been. Eventually further improvement took place.

A paper on "Porencephalus, in which Trephining was Done for the Relief of Local Symptoms; Death from Scarlet Fever; Exhibition of the Specimens," by Dr. De Forest Willard and Dr. J. Hendrie Lloyd, of Philadelphia, was read, in which was reported the case of a child, seven years old, with cerebral spastic hemiplegia. There were inability to walk and internal strabismus. The child was well developed. Sensation was unimpaired. There were convulsions, followed by enfeeblement of the mental faculties and athetoid movements of the right arm. As the child was rapidly growing worse, trephining was performed. Three days after the operation scarlatina developed and the child died on the eighteenth day. The autopsy disclosed no evidences of meningitis, but a condition of porencephalus involving the Rolandic region.

Dr. C. L. Dana, of New York, admitted the validity and utility of operation in certain cases. He maintained conservative views as to the propriety of operating in cases of Jacksonian epilepsy, tumors, for the relief of pain, and in porencephalus, and was desirous of hearing opinions as to the details of excision of the cortex and as to operation for infantile cerebral hemiplegia. Such cases are often associated with epilepsy, imbecility or idiocy. Dr. Dana had obtained the histories and the specimens in twelve cases of cerebral tumor that were not operated upon. Three could have been recognized, localized and operated upon. In two others, sarcomata occupied the middle of the central convolutions.

Dr. B. Sachs, of New York, stated that the result of surgical interference in focal epilepsy was particularly distressing. It had been shown that after removal of the focus the secondary degeneration also involved the cortex. In cases of tumor, operation promises the more favorably as secondary degeneration is the less thoroughly established. In focal epilepsy, improvement may be secured, but not cure. Dr. Sachs believed that in no case has there been freedom from attacks for two years after the operation. It would seem that operations upon cases of porencephalus would but tend to increase the size of the existing cavity. Cases should be carefully selected or the operation would fall into discredit. In porencephalus the motor symptoms are decided, while the mental symptoms are slight. The

evidence points to a pre-natal condition rather than to an acquired cerebral palsy. Cases of the latter kind are suitable for operation if seen at an early stage. Such a condition is frequently due to meningeal hemorrhage, and operation should be performed early. If secondary degeneration has taken place, the operation will prove useless.

DR. C. B. NANCREDE, of Ann Arbor, related a case in which no spasm had occurred for three years after operation. In focal epilepsy of long standing, he believed that hernia cerebri occurred as a result of encephalitis.

DR. BREMER, of St. Louis, called attention to the importance of testing the muscular irritability by applying the faradic current to the shaved scalp. He had found the irritability greater on the affected side. He reported a case of successful operation for focal epilepsy, with the results of an examination of the portions of the cortex excised. There were no changes in the cellular elements, but there was profound hemorrhage into the intravascular spaces. This admonishes the avoidance of too much pressure on the cortex during operation.

DR. E. P. DAVIS, of Philadelphia, expressed the view that meningeal hemorrhage in the newborn is generally due to disease of the mother, such as chronic nephritis; in this way a tendency to vascular degeneration is transmitted to the infant, with a predisposition to hemorrhage. He believed in the propriety of early surgical interference only in marked cases. The results are unsatisfactory if the mother has suffered from constitutional disease.

DR. BULLARD, of Boston, reported a case in an adult with hemiplegia and epilepsy, in which trephining was performed and the hemiplegic cyst evacuated. No attacks occurred in the subsequent two months.

DR. J. J. PUTNAM, of Boston, stated that one may be deceived in concluding that there must be focal disease because there are local spasms. Even diffuse lesions may give rise to focal sypmptoms. This fact explains some of the unsuccessful results of excision.

In closing the discussion, DR. KEEN said he was not aware of the character of the tumor at the time of operation. It is possible that its removal, without excision of the cortex, would have been the better operation. In no case had he observed a positive or permanent cure. The operation was warranted by the probability of the relief it was expected to afford. He had in this case on microscopical examination been unable to verify the existence of secondary degeneration. Cases of defective development, such as porencephalus, should not be operated upon, but, in cases of microcephalus, operation may prove beneficial, although the patient is exposed to great danger. In thirty-seven such cases there were nine deaths.

DR. WILLIAM A. HAMMOND, of Washington, read a paper on "Seven Recent Cases of Brain Surgery," which is to be published in a subsequent number of THE MEDICAL NEWS.

DR. J. H. LLOYD, of Philadelphia, reported a case of tumor of the mesencephalon, and exhibited the specimen.

DR. B. SACHS, of New York, read a paper entitled "Tuberculous Infection of the Central Nervous System," in which he reported two cases of non-tuberculous disease of the central nervous system in which exposure to tuberculous infection was followed by aggravation of the existing symptoms, with a fatal termination.

DR. E. D. FISHER, of New York, read a paper on "Lead-poisoning with Special Reference to the Spinal Cord and to Peripheral Nerve Lesions," which is to appear in a future number of THE NEWS.

DR. WILLIAM C. KRAUSS, of Buffalo, N. Y., exhibited a neuro-topographical bust, designed to show the topography of the nervous system of the head and neck. The bust is of plaster, life-size, and offers the following special features: The fissures of the brain are represented by grooved lines, deep or shallow, according to the size of the fissures in the human brain. In order to render them more distinct and visible they have been painted black. On the face and neck are represented the various electro-motor points of the muscles and nerves as determined by Erb, v. Ziemssen, and others. The motor points of the nerves are represented by circles, slightly raised and painted yellow. The course of the phrenic nerves and the brachial plexus in the neck are shown by slightly grooved lines, also painted yellow. In contrast to the nerves, the motor points of the muscles are represented by smaller circles, painted red. The various points may be designated by small printed slips or by figures and a reference table.

The bust is recommended for the use of neurologists in making comparisons, and in cerebral surgery as a guide in seeking the various centers of the brain.

THIRD DAY—SEPTEMBER 24TH.

DR. G. L. WALTON, of Boston, reported a case of "Removal of a Neuroma, Followed by Disappearance of Local Anesthesia of Fourteen Years' Standing." Fourteen years ago Prof. B., aged twenty-nine years, cut his left index finger with a chisel. The injury left a sensitive cicatrix over the seat of the nerve, and complete anesthesia of the region supplied by it. Within a year of the date of consultation, numbness and tingling spread up the wrist and forearm, with pain and tenderness of the nerve-trunk (neuritis?). A region of numbness existed on the chest, and another on the thigh. There were general loss of nutrition and troublesome insomnia, with a history of continuous overwork. After a brief trial of general remedies and galvanism (with no result beyond some improvement in general condition), the nerve was cut down upon by Dr. M. H. Richardson. A neuroma was found involving the whole nerve-branch. This, with a portion of the nerve, was removed. The acute symptoms disappeared rapidly, and the long-standing numbness of fourteen years more slowly, sensation in the finger being perfect four months after operation. The case shows that the duration of anesthesia may be practically disregarded in considering the question of operation upon a peripheral nerve.

DR. GEORGE W. JACOBY, of New York, read a paper on "The Electro-physiology of Reflexes, with a Description of a Hitherto Unknown Localized Physiological Reflex Phenomenon." He stated that in the course of his observations he had discovered a reflex contraction of muscles of the chin when the negative pole of a galvanic battery is applied to the radial side of the forearm. Examination of 200 persons showed that the reflex was

present in over 70 per cent. of normal individuals. In no normal case could a reflex be obtained except upon kathodal closure. All kinds of mechanical excitation were also fruitless. In certain pathological cases an anodal reflex was obtainable; in certain others an anodal reflex was produced before a kathodal one, and in still others the contraction showed also a quantitative change.

Dr. V. P. Gibney, of New York, read a paper on "Supplemental Treatment of the Paralysis of Acute Anterior Poliomyelitis," which appears elsewhere in the current number of The Medical News.

Dr. Walter Channing, of Boston, read a paper entitled "Deformity of the Palate in Idiots." He presented a series of charts and plaster casts showing the formation of the palate in one hundred and fifty cases of idiocy. The cases were classed into average, neurotic, and deformed, of which there were respectively 43, 30 and 37 per cent.

Dr. Irving C. Rosse, of Washington, read a paper entitled "Triple Personality," in which he reported the case of a man, thirty-five years old, who presented "triple delusions," believing that, in addition to himself, he was a "young man" and "Lucifer." This mental condition had remained unchanged, with the exception of about three months of comparative latency of the delusions nine months before, since when gradual impairment of the mental faculties had left the patient in a state of dementia.

Dr. Landon Carter Gray, of New York, read a paper upon "Intra-cranial Syphilis," in which he dwelt upon a complex of symptoms including cephalalgia, irregularly periodical, generally recurring at night, occasionally in the afternoon or in the morning, and associated with insomnia. The symptoms disappeared upon the development of palsy. Dr. Gray maintained that hemiplegia developing in middle age should arouse a suspicion of a syphilitic origin. Headache and insomnia are indicative of an early stage of intra-cranial syphilis, although they may appear later.

Dr. Mills, of Philadelphia, stated that the development of paralysis upon the subsidence of headache and insomnia was unimportant diagnostically and therapeutically. The symptoms occurred as a result of degenerative changes.

Dr. William Osler, of Baltimore, read a paper upon "Double Athetosis," based upon fifty-three cases reported and numerous personal observations. He believed that athetosis is compatible with a high degree of intelligence, but is usually accompanied by mental impairment.

Dr. Charles K. Mills, of Philadelphia, reported a case in which an apoplectic seizure was followed by deafness, which became more decided after a second attack, with the appearance of partial left-sided paralysis. At the autopsy, lesions were found in the first and second temporal convolutions of both hemispheres. Dr. Mills also reported a case in which a subcortical hemorrhagic cyst was found beneath the arm and leg areas.

Dr. James Hendrie Lloyd, of Philadelphia, read a paper entitled "Tumor of the Mid-brain and Left Optic Thalamus," which is to appear in The Medical News.

Dr. J. J. Putnam, of Boston, referred to the case of a child with double athetosis, in which post-mortem no lesion could be found. At the autopsy in a case of hemichorea, there was a distinct spot of softening in the tegmentum of one side; in another patient, with locomotor ataxia without impairment of intelligence, there was a linear hemorrhage in the subcortical area beneath the paracentral lobule, with secondary degeneration in the cord. In a case of sensory aphasia operated upon, a cyst was found in the left temporal lobe.

Dr. L. C. Gray, of New York, reported the case of a man with hemiplegia and impairment of the muscular sense, in which, on operation, no lesion could be discovered. Death took place a day later. The autopsy revealed at the junction of the arm and leg centers a round-cell sarcoma undergoing cystic degeneration at the center.

Dr. C. L. Dana, of New York, reported the case of a man, forty-three years old, with a history of syphilis ten years previously, who presented headache, left hemiconvulsions and coma. On recovery, left hemiplegia and left hemianesthesia persisted. At the autopsy a gumma of the dura mater over the right central convolutions was found. In another case, in a man fifty-five years old, with progressive right hemiplegia and some loss of sensibility on the same side, a tumor about as large as a hen's egg was found in the middle of the left precentral convolution. Dr. Dana held that cutaneous sensations must have their representation in the cortex, having a larger and more diffuse representation than the motor. When one side is involved in disease, compensation takes place from the other side to a greater degree than in the case of motion or other sensations.

Dr. Philip C. Knapp, of Boston, reported the case of a child with athetosis from cerebral palsy, in which the autopsy disclosed hydrocephalus and basilar tuberculous meningitis. In another case, anesthesia was associated with a lesion of the motor cortex. He conceded that tactile sensibility was more largely represented posteriorly than anteriorly to the fissure of Rolando. Conversely, growths in the Rolandic region may occasion no motor paralysis.

Dr. J. W. Putnam, of Buffalo, reported a case in which, shortly after the removal of nasal polypi, memory became impaired. On the eighth day, owing to the absence of sensory or motor symptoms, a diagnosis of abscess of the left frontal lobe was made. On trephining, three ounces of pus were removed from the frontal lobe. At the autopsy, a second abscess was found in the frontal lobe of the opposite side. In another case, in which there was a spastic condition of all four extremities, a glioma at the base was found pushing the medulla to one side. In a child with athetosis involving the head as well as the extremities, there was an apparent absence of the bridge of corpus callosum and an abscess of each temporal lobe.

Dr. Bremer reported a case of excision of the wrist-center on the right side for focal epilepsy, in which neither paralysis nor other symptom followed the operation. The question of cortical motor and sensory areas is still unsettled. In the presence of spastic symptoms, the location of the tumor is not so important as is its character. The varying supply of blood to the hemorrhagic cyst probably occasions spastic symptoms.

In conclusion, Dr. Mills expressed the view that there exists a great sensory lobe, not the gyrus fornicatus or the hippocampal region, but a lobe with

anatomical demarcations. It may include the gyrus fornicatus, the quadrate lobe, and the posterior parietal lobule. These regions constitute subdivisions of this sensory lobe, corresponding to subcutaneous muscular groups. Dr. Mills thought that there must be a sensory-motor association tract as well as a sensory-motor audition tract. Cerebral paresthesia is comparable to paraphasia and paralexia.

DR. C. EUGENE RIGGS, of St. Paul, reported a case of paranoia in a young man who, in addition to other symptoms, had periods of double consciousness. The question was raised whether the patient's actions were prompted by the morbid egoism so common in paranoia or constituted a manifestation not infrequently associated with epilepsy.

DR. DAVID INGLISS, of Detroit, read a paper, entitled "Friedreich's Disease; Its Relation to Conducting Paths in the Cord," in which he developed the conclusion that the function of the posterior columns and of the direct cerebellar tract is not to transmit sensory impulses upward, but rather that they are the main channels for the transmission of coördinated motor impulses downward. The anatomical relations of these tracts with the midbrain and the cerebellum indicate that the tracts transmit coördinated impulses from the higher to the lower centers.

The paper of DR. J. T. ESKRIDGE, of Denver, on "Gunshot Wound of the Left Cuneus with Right Homonymous Hemianopsia," will appear in a later number of THE MEDICAL NEWS.

The paper by DR. C. H. HUGHES, of St. Louis, on "The Virile Reflex in Relation to Clinical and Forensic Neurology," was read by title. Dr. Hughes discussed his method of eliciting the "virile reflex," and set forth its relation to the analogous bulbo-cavernous reflex of M. Ouvanoff.

The novice, in seeking to elicit the clinical and physiological sign, may be inclined to doubt its existence, because some skill in palpation, a sort of *tactus eruditus*, is necessary in examining for it. The characteristic jerking-back of the bulbous urethra within the sheath of the penis can be felt only when carefully sought for, and it cannot ordinarily be seen.

The value of this sign in its clinical aspect is obvious, and in its medico-legal relations it must likewise be apparent, especially in questions of exaggerated, perverted, or lost virility. By it we may be aided in the solution of questions of morbid erotism, erotomania, nymphomania, satyriasis, psychical or physical lust, questions of rape from rational and purely lustful purpose or from morbid perversion and insane impulse, etc.

The paper of DR. J. T. ESKRIDGE, of Denver, entitled "Fracture of the Twelfth Dorsal Spine, Followed by Injury of the Spinal and Sympathetic Nerve-supply of the Bowel in the Region of the Ileo-cecal Valve, Intestinal Hemorrhage, and Death on the Seventh Day," appears in the current number of THE MEDICAL NEWS.

The following were elected to active membership: Dr. H. A. Tomlinson, of Philadelphia; Dr. Edward Cowles, of Somerville, Mass.; Dr. Henry H. Donaldson, of Worcester, Mass.; Dr. James Wright Putnam, of Buffalo, N. Y.; Dr. William Browning, of Brooklyn, N. Y.; Dr. Edward B. Angell, of Rochester, N. Y.; Dr. G. J. Preston, of Baltimore, Md.; Dr. Richard Dewey, of Kankakee, Ill.; Dr. Walter Channing, of Boston, Mass.

The following officers were elected for the ensuing year:

President.—Dr. C. L. Dana, of New York.

Vice-Presidents.—Dr. P. C. Knapp, of Boston, and Dr. E. N. Brush, of Baltimore.

Secretary and Treasurer.—Dr. G. M. Hammond, of New York.

Councillors.—Dr. Wharton Sinkler, of Philadelphia, and Dr. E. D. Fisher, of New York.

AMERICAN DERMATOLOGICAL ASSOCIATION.

Fifteenth Annual Meeting, held at Washington, September 22, 23, 24, and 25, 1891.

(Continued from p. 371.)

SECOND DAY—SEPTEMBER 23D.

DR. J. C. WHITE, of Boston, opened the discussion on Tuberculosis of the Skin. He presented "Its Clinical Aspects and Relations."

DR. JOHN T. BOWEN, of Boston, considered "The Pathology of Cutaneous Tuberculosis." He confined himself to the anatomy of the affection.

Baumgarten has shown that the fixed tissue-cells are the first to become impressed by the tuberculous virus, and are converted into epithelioid and giant-cell forms. While it may be questioned whether we are yet justified in regarding the epithelioid and giant-cells as derived in all instances from the fixed tissue-cells alone, it is now clear that the rôle of the white blood-corpuscles in tuberculosis, as well as in other chronic inflammatory processes, has been greatly exaggerated.

Four distinct varieties of cutaneous tuberculosis may be considered, viz.: miliary tuberculosis, scrofuloderma, lupus, and tuberculosis verrucosa cutis. Miliary tuberculosis of the skin occurs rarely. It is found at the entrance to mucous cavities, in persons suffering from advanced tuberculosis of internal organs, and is characterized clinically by painful ulcers with indented edges. Anatomically, this form of tuberculosis presents the characteristics of an acute process, with the presence of a large number of tubercle bacilli, and an advanced stage of necrosis. It is analogous to the acute tuberculosis of internal organs. Scrofuloderma represents a tuberculosis of the subcutaneous tissue and lower layers of the corium, and the tubercle bacilli, while less numerous than in the miliary form, are usually found in greater numbers than in lupus. In lupus the process has its starting-point in the lower portions of the corium, affecting the upper portions by extension. Lupus differs from other forms of tuberculosis in being less acute and more slowly progressive.

It was maintained that in tuberculosis verrucosa cutis the inflammatory complications, which are pronounced in some cases, are by no means constant. The number of tubercle bacilli found in the lesions may be small. Anatomically, tuberculosis verrucosa differs from lupus verrucosa in its more superficial seat, and in the early appearance of the papillary hypertrophy; the verrucous forms of lupus are usually consecutive to some degree of ulceration. In tuberculosis verrucosa cutis a direct inoculation can usually be proved to have taken place,

a mode of infection that has as yet been demonstrated in only a small number of cases of lupus.

Dr. G. H. Fox, of New York, discussed "The Treatment of Tuberculosis of the Skin."

In the subsequent discussion Dr. H. G. Piffard, of New York, said that the connection between what was called pulmonary consumption and lupus and the so-called scrofulodermata had long been surmised. Recent advances in microscopy had enabled the detection of tubercle bacilli in the lesions, and to establish the relationship on pathological grounds. Dr. Piffard expressed the belief that lupus erythematosus is entitled to the name "lupus," as he thinks it too is of bacillary origin. Cold abscess of the skin is probably due to the same cause, as is also rodent ulcer. He agreed with Dr. White in believing that there should be a collective term for all of the various tuberculous diseases. In treatment he advocated cutting out the whole diseased patch, unless it was very extensive. Next to the knife he placed the actual cautery, after removal with the curette of as much of the growth as possible. Arsenic and chloride of zinc are also to be depended on.

Dr. C. W. Allen, of New York, commended multiple scarification, and combined pyrogallol and mercurial plasters; he thought that there might yet be a future for tuberculin.

Dr. J. Zeisler, of Chicago, expressed himself as in thorough accord with Dr. White. His experience had converted him to the use of the galvano-cautery. He testified to the efficacy of the solid stick of nitrate of silver, which, bored into the skin, would act both as a knife and caustic. He was not enthusiastic as to tuberculin.

Dr. E. B. Bronson, of New York, believed that it was best to retain for some time our present terminology for the different tuberculous diseases. In regard to tuberculin, he had seen improvement in some cases treated with it, but on the whole his experience had made him regard the remedy unfavorably. He had had good success with the dental burr, as first advocated by Dr. G. H. Fox. The nitrate-of-silver stick was also good.

Dr. J. N. Hyde, of Chicago, was glad that Dr. White accepted local contagion as the cause of lupus, a view that he himself was among the first to advocate. He thought that in this country there were but few cases of lupus with a history of pulmonary tuberculosis in the family, or with tuberculous disease elsewhere. He did not believe in the treatment by scarification. Both the curette and nitrate of silver were serviceable in proper cases. In regard to tuberculin, he thought it possible that in time something of value might be found in it.

Dr. L. A. Duhring, of Philadelphia, preferred in private practice for the present to retain the old names. He had not found lupus associated with general tuberculosis. He recommended pyrogallol most highly, using it in the form of a plaster with resin and soap plaster—three of resin plaster and one of soap plaster—to be worn continuously. He had not found the local use of bichloride of mercury beneficial. He had found tuberculin helpful, though he could not report any case of cure.

Dr. P. A. Morrow, of New York, agreed with Dr. White that as lupus and some other diseases had a common etiological factor, we should place them together under a common heading. He advocated the use of multiple scarifications followed by mercurial plaster. For destruction of the small lupus nodules he recommended punctate cauterization with a white-hot instrument. Chloride of zinc is superior to pyrogallol as a caustic. Excision will probably increase in favor as a means of treating lupus.

Dr. L. D. Bulkley, of New York, expressed a want of satisfaction with any of the current plans for the external treatment of lupus. Internally, he has great faith in phosphorus as a curative agent, the nodulues softening and disappearing under its continuous use. As to pyrogallol, that too was admirable. He applies it in powder, pure, after scraping. Salicylic acid combined with pyrogallol is also useful.

Third Day.—September 24th.

Dr. L. A. Duhring, of Philadelphia, read a paper entitled "Notes of a Visit to the Leper Hospital of San Remo, Italy." In reply to a question he replied that no attempt at segregation was made in San Remo. There were but few cases in the hospital, and they were in an ordinary ward of a general hospital. They were not permitted to leave the confines of the hospital.

Dr. P. A. Morrow, of New York, then followed with a paper on "Skin-grafting," and showed a case in which the operation had been done by the method described, with admirable results.

Dr. Clarke asked if the inclusion in the graft of the deeper structures of the skin, as recommended, would give any better results than if the more superficial parts only were included. Dr. Morrow replied that he thought that the deeper grafts would be more certain to take, and he had had not a single failure. He had made more than fifty grafts of hairy skin upon a cicatricially bald scalp, and all of them had taken, and from many of them the hair was growing nicely.

Dr. L. D. Bulkley, of New York, read a paper entitled, "A Therapeutic Note on Alopecia Areata."

Dr. J. Zeisler, of Chicago, believed that alopecia areata was due to a parasite, though perhaps some cases are dependent upon a neurosis. The latter were most obstinate. He was in favor of treating all cases by epilation about the patches. He had no success with pilocarpine. He regarded a concentrated solution of common salt as a good remedy for stimulating the growth of the hair.

Dr. W. T. Corlett spoke in favor of acetic acid as a remedy in alopecia areata. Some cases, however, recover spontaneously.

Dr. G. H. Fox was always pleased to hear anyone speak with confidence of any treatment of alopecia areata, as Dr. Bulkley had done of carbolic acid. He was rather skeptical of any remedy. In his hands a strong solution of ammonia had proved as effective as any remedy. He thought that general treatment of the patient was quite as important as any local application.

Dr. J. E. Graham had never seen any cases that would lead him to believe that alopecia areata was contagious. He did not think that, because antiparasitic remedies were useful, this was a proof of the parasitic nature of the disease.

Dr. P. A. Morrow thought that there had been a sufficient number of cases of contagion reported to remove any reasonable doubt of the contagiousness of the disease.

He quoted an instance in which a number of cases were traced to one barber. He had seen one case of probable contagion.

DR. L. A. DUHRING said that in spite of a careful study of alopecia areata he had never been able to find any parasite in the disease; nor was he convinced that the disease was contagious. He believed that there was a disease simulating alopecia areata, and often reported as such, that sometimes occurred epidemically, but was not alopecia areata. He regarded arsenic taken internally as very valuable in the treatment of the disease. He could see no reason for epilating the healthy hair about the patches.

DR. J. C. WHITE said that positive evidence of both the parasitic and the neurotic element in the etiology of the disease was still wanting. Clinical evidence points both ways. He had seen cases of apparent contagion. He had seen thirty cases of a disease simulating alopecia areata occurring in an asylum, which were not cases of ringworm, but were probably instances of so-called contagious alopecia areata. He did not think that they were true alopecia areata. His favorite remedy was a lotion consisting of half a dram of croton oil to eight ounces of turpentine, used daily. Of course, it failed in some cases, as do all remedies. If it failed, he used other remedies that had been commended, but they did not do any better. He did not believe that there was any specific remedy.

DR. H. W. STELWAGON had never been able to trace a case to a contagious origin. Local stimulation is more to be relied on in treatment. He was fond of equal parts of turpentine, cantharides and tincture of capsicum, with arsenic internally.

DR. J. N. HYDE believed that the time would come when alopecia areata would be regarded as simply a symptom. Some cases were doubtless parasitic and some neurotic in origin. In bad cases he used creasote locally. After, say, from the forty-fifth to the forty-eighth year of life, the chances of recovery are greatly decreased.

DR. H. G. KLOTZ had had one case in which hereditary syphilis was probably the underlying cause, the boy getting better under specific treatment.

DR. W. C. ALLEN believed that the disease was parasitic and thought that he had in his own practice observed a case of contagion. He thought that internal treatment was valuable. Naphthol and pyrogallol had both proved useful in his hands.

DR. J. GRINDON had never met with a case that suggested either a parasitic or contagious origin of the disease. He believed in its tropho-neurotic origin.

DR. F. B. GREENOUGH in practice used a half-dram of carbolic acid in an ounce of water as a lotion.

DR. L. D. BULKLEY said that he applied the 95 per cent. solution of carbolic acid to a small portion only of the scalp at a time. It should be brushed over lightly at first, so as to benumb sensibility, and then rubbed in more thoroughly. He had not used it elsewhere than on the scalp. The skin is red for a few weeks; this disappears and the hair grows. He also administers strychnine and phosphoric acid, and keeps up the nutrition of the patient.

DR. R. W. TAYLOR, of New York, read a paper entitled "Angioma Pigmentosum et Atrophicum," by DR. A. W. BRAYTON, of Indianapolis.

DR. J. C. WHITE stated that his investigations showed that the disease was not limited to Russian Jews, but was met with also in persons of English and of French descent.

DR. L. A. DUHRING read a paper entitled "Experiences in the Treatment of Chronic Ringworm in an Institution for Boys."

In the discussion, DR. G. H. FOX said that he had found chrysarobin useful, as had Dr. Duhring. He began the treatment by clipping the hair short and shaving, either only over the patches or over the whole scalp, and applying chrysarobin in solution. He disliked greasy applications. Hydronaphthol plaster, as recommended by a European physician, had proved more satisfactory than chrysarobin. He advocated epilation when practicable.

DR. J. ZEISLER advocated pyrogallol as a parasiticide.

In reply to a question, DR. DUHRING said that some of the cases recovered in six weeks, and some not for a year.

DR. WHITE thought that white chrysarobin was a good remedy; it was not a safe one to use outside of an asylum or hospital. He recommended a combination of sulphur, carbolic acid, and naphthol, made into an ointment.

DR. STELWAGON recommended an ointment composed of tar, sulphur, and citrine ointment.

DR. SHERWELL advised keeping the scalp saturated with a mild oil and covered by a skull-cap.

In concluding, DR. DUHRING said that the cases were all well when the treatment was withdrawn, and that they remained well for at least one year. Epilation did not repay the vast amount of labor it cost. He regarded ointments as most useful remedies.

DR. J. ZEISLER, of Chicago, then read a paper on "Epilation: Its Range of Usefulness as a Dermatotherapeutic Measure."

In the discussion, DR. G. H. FOX said that he was glad to hear anyone advocate epilation in sycosis, as he had found it a most useful remedy. After epilation, a sulphur paste is valuable. He had not found epilation so promptly curative as had Dr. Zeisler, while he laid more stress on dietetic management than did the latter. He was sure that epilation was useful in some cases of chronic ringworm of the scalp.

DR. H. G. KLOTZ also spoke in favor of epilation in sycosis, though he had cured many cases without it, notably with mild naphthol ointments. He thought epilation valuable in syphilitic lesions about the hairs, as well as in all the pustular affections implicating the hair.

DR. L. A. DUHRING had not been able to practise epilation on his patients on account of the pain it caused, especially on the upper lip. He could not see much use in epilating in alopecia areata when the hairs about the patch were firm.

DR. P. A. MORROW said that he did not think it necessary to pull out all the hairs about the bald patches, but it was a good thing to make traction on all of them and to remove all that were loose. Epilation was a requisite in all rebellious cases of trichophytosis. If the hair is removed by a quick, sudden movement, the operation is nearly painless.

DR. H. W. STELWAGON believed that many cases of

sycosis could be cured without epilation. He would speak in special praise of Fleming's solution in trichophytosis, diluting it at first one part to five or six of water, and gradually increasing the strength to just short of marked irritation.

Dr. S. Sherwell spoke of the connection between catarrhal conditions of the nose and sycosis of the upper lip.

Dr. J. H. Hyde said that the last time he was in London and Paris he had observed that epilation was quite generally practised about the patches of alopecia areata.

In closing, Dr. Zeisler said that when epilation was properly performed it was almost painless. As he regards alopecia as a parasitic disease, spreading at the periphery, he epilated about the patches to stop their spreading.

Fourth Day—September 25th.

Dr. J. E. Graham, of Toronto, read a paper on "Molluscum Contagiosum."

Dr. Bowen said that there was little question but that the disease was contagious. It is still unproved whether certain bodies found in molluscum are or are not coccidia.

Dr. Allen had no doubt about the contagiousness of the disease, and related cases in an asylum spreading from one case. Excision is never necessary. The nodules can readily be squeezed out, and then lightly touched with a caustic. He believed in their parasitic origin.

Dr. J. C. White, while believing that molluscum was contagious, was not prepared to accept the psorosperm as its cause.

Dr. J. N. Hyde pointed out that in the statistics for the year just closed, 17 cases of molluscum contagiosum were reported, viz.: 9 from Boston, 5 from New York, 2 from Chicago, and 1 from St. Louis.

Dr. F. B. Greenough believed the disease to be contagious. In treatment he simply bores into the formation with nitrate of silver stick.

Dr. J. E. Graham thought from evidence so far brought forward that the so-called psorosperms were simply degenerated epithelial cells.

Dr. J. N. Hyde, of Chicago, then read a paper entitled "Note Relative to Pemphigus Vegetans."

In the discussion, Dr. L. A. Duhring said that he had had the opportunity of seeing the case described and would corroborate what Dr. Hyde had said of it. It certainly was more of the nature of pemphigus than of anything else.

Dr. Bowen had seen a case of Neumann's in Vienna, and this one brought that one back very vividly to his mind. He regarded the term "pemphigus" as a most indefinite one, and thought that it gave very little idea of the pathology of the case under discussion.

Dr. S. Sherwell had seen a case in a woman with analogous symptoms, which was cured by ovariotomy.

Dr. J. E. Graham related the history of a similar case of his own. It became much better under arsenic but suffered a relapse.

Dr. J. N. Hyde, in closing, said that in his case there was no disease of the ovaries. He regarded the prognosis in his case as not good.

Dr. H. W. Stelwagon then read a paper on "A Study of Mycosis Fungoides."

Dr. Hartzell emphasized the infectious nature of the tumors, and thought that we must look to inoculation experiments for proof.

Dr. Bowen spoke of the disagreement among pathologists in regard to the exact nature of the tumors.

Dr. Duhring said that the disease was a general one of the skin, and did not to any extent seem to affect other organs. He believed it to be an infectious disease. It may be regarded as on the border-line between an inflammatory new-growth and a tumor.

Dr. Fox related a case of apparent infection of the disease in the New York Skin and Cancer Hospital. He also spoke of the early diagnosis of the disease, and reported a case that at first looked like eczema marginatum, but afterward developed the characteristic tumors.

Dr. Stelwagon, in closing, said that in looking up the literature of the disease he had found some fifty or a hundred reported cases. It was exceptional for the disease to begin as tumors.

Dr. M. B. Hartzell, of Philadelphia, then read a paper on "Lymphangioma Circumscriptum, with Report of a Peculiar Case," which is to appear in The Medical News.

Dr. C. W. Allen then made some remarks on "Erythema or Nævus Nuchæ."

Dr. Zeisler thought it probable that erythema nuchæ was often due to pressure and rubbing.

Dr. Joseph Grindon, of St. Louis, Mo., read a paper on "A Case of Lichen Ruber." This case is placed under the above caption inasmuch as, although differing in several important particulars from the hitherto reported American cases, it tallies in most points with the descriptions of the younger Hebra. The writer believes that the constitution and limitations of the lichen group are still far from being settled, and would provisionally class as lichen ruber cases of chronic papular inflammatory dermatoses not readily falling in with any of the other better-defined members of the group, such as L. planus or L. scrofulosus.

The disease in this instance was characterized by the formation of firm, hard, red papules of rounded outline and profile, little or not at all scaly, intensely pruritic, of very slow evolution, occurring first on the face and after several years spreading to the body and extremities. The hairs and nails were implicated, but there was no marked depreciation of the general health. The papules after a longer or shorter interval tended to form patches, by the appearance of new lesions among the older ones. These patches finally lost all trace of a papular origin, but were divided up by deepening of the normal furrows, consequent upon the thickening and infiltration. The disease showed several partial remissions, and one period of apparent cure extending over several months. The best results were obtained from the persistent use of Unna's carbolic-sublimate salve. Arsenic had no appreciable effect.

Dr. Zeisler was inclined to view the case as one of lichen planus. In this disease plantar and palmar thickenings are apt to form. Arsenic often cures these patients.

Dr. S. Sherwell agreed with Dr. Zeisler in his diag-

nosis, though the case presented many exceptional fearures, especially the involvement of the nails.

DR. HYDE said that he always found the polygonal outline of the papules to be well marked, something that does not seem to be familiar to the Germans and the French.

DR. DUHRING agreed with the previous speakers in this diagnosis. The polygonal shape and umbilication are often wanting.

AMERICAN LARYNGOLOGICAL ASSOCIATION.

Thirteenth Annual Meeting, held at Washington, September 22, 23, and 24, 1891.

FIRST DAY—SEPTEMBER 22D.

DR. W. C. GLASGOW, of St. Louis, delivered the Presidential Address, in which he reviewed the progress of the science of laryngology, and especially the influence that had been exerted by the American Laryngological Association, in rescuing the practice of laryngology from charlatans and giving it a prominent and honorable position among the special fields of practice. Appropriate action was taken with regard to the death of Dr. E. Carroll Morgan, who, as President of the Association, occupied the chair at its last meeting in Washington, two years ago. A minute was also made of the death of another member, Dr. Hosmer A. Johnson, of Chicago, who died since the last session.

DR. GLASGOW read a paper entitled "A Case of Foreign Body in the Trachea." A child, eight years old, was said to have swallowed, two hours previously, a toy balloon with a whistle attached. There were paroxysms of suffocation, in the intervals between which the child appeared to be perfectly well, without any interference with respiration. While under examination, the child suddenly became aphonic, struggled for breath, lost consciousness, and frothed at the mouth. The paroxysm passed off in a few minutes, and the child resumed its normal condition. It could swallow water, and a bougie had been passed into the stomach, showing that the esophagus was clear. By inspection, the larynx appeared unobstructed. Chloroform anesthesia was so poorly borne that a thorough examination was not made. It was concluded that the manifestations were hysterical or epileptic. Finally, after tracheotomy was performed, the rubber part of the balloon was seen to project into the lower part of the tube, and was extracted through the tracheal wound; subsequently the wooden whistle was extruded through the glottis, and the child recovered. In the interval between the paroxysms there was slight enfeeblement of breathing over the left lung.

DR. CLINTON WAGNER, of New York, read a paper entitled "A Case of Thyrotomy in a Child Eighteen Months Old." He said that thyrotomy should only be resorted to for the relief of urgent dyspnea arising from laryngeal obstruction, either by a benign growth or a foreign body, in order to accomplish the removal of such obstruction. In a case of malignant disease, it is only permissible when there is a reasonable chance of removing all diseased tissue. In tuberculosis of the larynx it is unjustifiable. Dr. Wagner had performed the operation ten times; six of the cases perished, but not as a result of the operation. The remaining four cases, all in children, recovered. The case reported was that of a neglected child suffering with dyspnea, the cause of which was uncertain. Two weeks after a preliminary tracheotomy, thyrotomy was performed, and a small papilloma was detected near the posterior extremity of the left cord and removed. The child did well for ten months after the operation, when he succumbed to an attack of croup.

In the discussion, DR. INGALLS, of Chicago, advocated the use of the index-finger for diagnostic purposes.

DR. MULHALL, of St. Louis, commended the finger-nail as a useful instrument for the removal of small superficial papillomata of the vocal bands.

In young children, under two or three years of age, DR. WAGNER considered the removal of papillomata by the mouth entirely impracticable.

DR. HARRISON ALLEN, of Philadelphia, read a paper on "The Tonsil in Health and Disease." He considers the tonsils analogous to Peyer's patches in the small intestine. He held the operation of amputation of the tonsils as unscientific and unnecessary. In many cases, the enlargement of the tonsils subsides without direct treatment, if the adenoid tissue in the naso-pharynx is restored to a healthy condition. Dr. Allen therefore recommended primary operation upon existing pharyngeal growths. When bands of cicatricial tissue stretch across the surface of the tonsil, obstructing the openings of the crypts of the gland, he advocated cutting such bands in order to relieve tension and favor expulsion of the contents of the crypts. Subsequently, astringent applications are made by means of a probe carried into the crypts, which Dr. Allen prefers to the cautery or knife.

DR. JONATHAN WRIGHT, of Brooklyn, said that it was his experience that when he removed a pair of enlarged tonsils, the adenoid tissue above disappeared spontaneously. He held that the tonsils both caused irritation and dammed up the secretions, and thus led to pharyngeal disease.

DR. JOHN O. ROE, of Rochester, advocated the evacuation of abscess in the tonsil by means of sharp scissors, which are used closed as a probe and opened only after introduction, cutting only so much as may be needed and avoiding large vessels.

DR. CLARENCE C. RICE, of New York, read a paper on "The Troublesome Symptoms Caused by Enlargement of the Epiglottis and the Advisability of Reducing the Size of this Cartilage by Operative Measures." Many deformities of the epiglottis are recognized, especially those occurring in the course of pulmonary tuberculosis, lupus and syphilis. When the epiglottis is the seat of a chronic morbid process, or the lingual tonsil is enlarged so as to cause irritation, there arise a sense of fulness and tickling in the throat and frequent cough. In addition to the edema, tumefaction and inflammatory swelling of the overlying tissues, the cartilage itself is actually increased in size. The epiglottis may congenitally be abnormally large; more frequently the increase in size is caused by injuries, the excessive use of tobacco, alcohol, and by local inflammatory disturbances. Under the latter conditions Dr. Rice advised the removal of a portion of the enlarged part with long-bladed scissors or cutting-forceps. He had operated thus in two cases, using cocaine applications followed by albolene. He did not approve of the employment of the

epiglottitome of Mackenzie, and had found the galvano-cautery objectionable because the resulting burns are long in healing. The same objection applies to the use of the hot snare. The operation of removing part of a permanently enlarged epiglottis is applicable for cases in which astringents and ordinary treatment have failed.

Dr. Wagner stated that in a case of carcinoma of the epiglottis, reported ten years ago, he removed the entire epiglottis by the sub-hyoidean method, and no ill-effects followed. Dr. Wagner considered the partial removal advocated by Dr. Rice a justifiable procedure.

In the discussion on the "Result of Treatment of the Upper Air-passages in Producing Permanent Relief in Asthma," Dr. Bosworth insisted upon a recognition of the general morbid condition in cases of true asthma. He distinguished three factors in every attack: 1, The peculiar neurosis; 2, some external, perhaps atmospheric, excitant; and 3, frequently some local condition in the nose that entails unusual susceptibility to certain irritants. In a large proportion of cases a restoration of the normal respiratory function and a removal of obstruction from the nose or upper air-passages confers immunity from future attacks.

Dr. Bosworth did not insist upon a nasal factor in every case of asthma, but when such abnormality was found it should receive appropriate treatment.

Dr. Mulhall, of St. Louis, presented a right-angled laryngeal cutting-forceps with a novel hinge.

Dr. Asch, of New York, presented a new intra-nasal galvano-cautery electrode, with the handle at an angle, so as not to obstruct the view.

Second Day—September 23d.

Dr. Jonathan Wright, of Brooklyn, read a paper on "Nasal Papillomata." He contended that nasal papillomata are extremely rare, and that the name is misleading. He preferred the designation "papillomatous fibroma." What have generally been mistaken for papillomata, upon investigation prove to be ordinary hypertrophic inflammatory masses or glandular hyperplasia, principally involving the inferior turbinated body. True papillomata, as a rule, occur upon the septum, in conformity with the observation that the muco-cutaneous junctions are the favorite sites for epithelial proliferations.

Dr. Jarvis advocated the employment of chromic acid to cauterize the bases of these growths after their removal, which always prevents their return.

Dr. J. Solis-Cohen proposed the name of dendritic vegetations for the so-called papilloma.

Dr. E. L. Shurly, of Detroit, read a paper entitled "A Study of a Case of Nasal Tuberculosis." The subject was a monkey with nasal catarrh and a profuse discharge containing tubercle bacilli. The discharge was diminished by the employment of antiseptics. The monkey was subsequently killed, but no tuberculous lesions were detected in the lungs or other viscera. It appeared to be simply a case of local tuberculous infection limited to the nose.

Dr. Chas. L. Knight, of New York, read a paper on "Cysts of the Middle Turbinated Bone." He considered the affection rather frequent, but often unrecognized. Of the two theories proposed to account for the development of the cysts—(1) rarefying osteitis, and (2) hypertrophic rhinitis—he believed the latter the more probable. An ossific projection growing from the middle turbinated bone gradually curls upon itself until, finally meeting the body of the bone, it forms a closed cavity. Such cavity, being lined with ciliated epithelium, contains mucous secretion, and, if inflamed, muco-pus. Operative treatment is simple: the cyst cannot be removed entire, but is extirpated, and antiseptic dressings are applied. These cysts occur only in connection with the middle turbinated bone, and none of the cases was under twenty years of age.

Dr. F. H. Bosworth, of New York, read a paper on "Various Forms of Ethmoid Disease," based on an analysis of twenty-seven cases that had been under treatment during the past five years. He distinguished five varieties, reporting illustrative cases of each: First, extra-cellular myxomatous degeneration, without purulent discharge; second, extra-cellular myxomatous degeneration, with purulent discharge; third, purulent ethmoiditis with nasal polypi; fourth, intra-cellular myxomatous degeneration without pus; and, fifth, intra-cellular myxomatous degeneration with pus.

The second variety may be regarded as a later stage of the first, while the fifth is a later stage of the fourth, thus reducing the varieties to three. For the first and second, as well as for the fourth and fifth varieties, no definite cause was assigned. The third variety may be regarded as the direct result of the nasal polypi, and not as a cause, as has been stated. This view is substantiated by the fact that in a majority of cases the ethmoid disease was accompanied with purulent disease of the antrum.

The diagnosis is based on careful ocular inspection, and a nice tracing of the source of pus-discharge. The diffuse myxomatous degeneration, so frequently seen covering the middle turbinated bone, should in the majority, if not in all cases, be accepted as evidence of a diseased condition of the mucous membrane lining the ethmoid cells. The treatment of all forms consists in uncovering the ethmoid cells by removing the convex cap of the middle turbinated body by means of the snare, and subsequently breaking up and destroying, as far as possible, the trabeculæ by means of the electric burr or the curette.

Dr. W. E. Casselberry, of Chicago, read a paper on the "Radical Treatment of Nasal Myxomata," in which the ground was taken that the best results follow extirpation of the base from which the myxomata grow. In two-thirds of the cases, myxomata develop in connection with or beneath the middle turbinated bone. They rarely develop from flat surfaces, but generally from free borders or edges. From the effects of hypersecretion the mucous membrane becomes sodden and furnishes a good soil for the growth of myxomata. Such a soil is found upon the free edge of the middle turbinated bone, and hence the frequency of their occurrence in this situation. These growths may be removed with curved scissors or with punch-forceps, and if part of the bone is removed at the same time it is generally an advantage, although not too much should be taken away for fear of occasioning cerebral mischief. The site of the growth can be touched with the cautery.

THIRD DAY—SEPTEMBER 24TH.

DR. J. SOLIS-COHEN, of Philadelphia, considered "The Symptoms and Pathological Changes in the Upper Air-passages in Influenza." The prominent changes are lymphoid infiltration of the soft parts, causing more or less edematous swelling of the soft tissues. The disease affects both the lymphatic and sanguineous vascular systems, differing in its manifestations in accordance with the structures most affected. Dr. Cohen incidentally mentioned a curious effect of influenza upon the course of other disease. In an old gentleman suffering with epithelioma of the palate, the patch of malignant disease sloughed during an attack of influenza and perfect recovery ensued.

DR. W. C. JARVIS, of New York, presented a communication entitled "Useful Deductions Derived from the Study of a Case of Cicatricial Contraction of the Larynx, Possessing Unusual Clinical Features, with Exhibition of Specimen."

DR. J. SOLIS-COHEN examined the specimen and said that below the constriction there was a normal larynx.

DR. MACKENZIE reported a case in which attacks of dyspnea were caused by a gumma that compressed both recurrent laryngeal nerves. The trachea had its lumen so narrowed above its bifurcation that it was with the greatest difficulty that a fine probe could be passed through the stricture. Tracheotomy was performed, but the dyspnea was not relieved, and after death the condition reported was found.

DR. ASCH suggested intubation and dilatation, with tracheotomy, if necessary.

DR. MORRIS J. ASCH, of New York, reported "A Case of Epithelioma of the Larynx." The patient was a healthy, vigorous man, fond of hunting, and unusually strong and active. He naturally had great irritability of the larynx, rendering examination difficult. The symptoms began with hoarseness and pain. In a few months the characteristic appearances of carcinoma of the larynx developed, with cough and dyspnea. Preliminary tracheotomy was performed, and subsequently the larynx was extirpated. In performing tracheotomy, Dr. Asch recommended the injection under the skin along the line of incision of a few drops of a 2 per cent. solution of cocaine as a local anesthetic, in preference to the employment of ether or chloroform, to produce anesthesia. By this means the operation is made absolutely painless. The patient was relieved, but subsequently had attacks of spasmodic dyspnea, during one of which he died, while suffering from weakness due to influenza.

DR. J. N. MACKENZIE, of Baltimore, presented a communication entitled "The Laryngo-tracheal Neoplasms of Tuberculosis." He recognized the following varieties: (1) That which is ordinarily known as papillary hyperplasia. (2) Papillary, warty growths, having nothing to distinguish them clinically from ordinary papillomata. These may be removed with the cold snare, but in tuberculous neoplasms, operations are deprecated, unless the growth, by its size, encroaches to a dangerous extent upon the lumen of the tube. (3) A solitary form of tuberculous tumor first described some twelve years ago by Dr. Mackenzie.

In the discussion on "The Relation of Disturbance of the Mucous Membrane of the Upper Air-passages to Constitutional Conditions," DR. MULHALL spoke in favor of hygienic treatment of nasal catarrh, and cited two cases in which the symptoms disappeared after the patients, who were pugilists, went into training.

DR. S. SOLIS-COHEN defined struma as a consequence of hypotrophy.

The following officers were elected for the ensuing year:

President.—Dr. S. W. Langmaid, of Boston.

Vice-Presidents.—Dr. Morris J. Asch, of New York; Dr. S. Johnston, of Baltimore.

Secretary and Treasurer.—Dr. Charles H. Knight, of New York.

Librarian.—Dr. Thomas H. French, of Brooklyn.

Member of Council.—Dr. William C. Glasgow, of St. Louis.

It was voted to ratify the action of the Council in transferring the Library to the Surgeon-General's office, where it will be held intact.

After some discussion, the limit of membership was increased from fifty to seventy-five.

Dr. J. H. Bryan, of Washington, D. C., was elected a Fellow of the Association.

The next meeting will be held at Boston, at a time to be fixed by the Council.

AMERICAN PEDIATRIC SOCIETY.

Third Annual Meeting, held at Washington, September 22, 23, 24, and 25, 1891.

(Continued from p. 384)

THIRD DAY—SEPTEMBER 24.

DR. W. P. WATSON read "A Report of a Case of Tuberculous Ostitis of the Hip-joint in a Child Born at Colorado Springs," by DR. JOHN M. KEATING, of Philadelphia. The father was in an advanced stage of pulmonary tuberculosis when the child was born. The boy was six years old and the picture of health. The case is a rare one, as Dr. Keating could find the records of only five or six cases of tuberculous joint-disease originating in Colorado Springs during a period of more than fifteen years, though a large portion of the population of 15,000 are or have been tuberculous.

DR. CHARLES W. EARLE, of Chicago, was not present, and his paper, entitled "Manifestations of La Grippe in Children," was read in abstract by DR. A. SEIBERT, of New York.

DR. J. O'DWYER, of New York, gave an exhibition of laryngeal tubes for the performance of forcible respiration. The instrument consists of a hollow, annulated cone, which is screwed to a curved tube with two openings, the upper being surrounded by a metal shield and the lower being supplied with a rubber tube attached to an ordinary laboratory bellows.

Dr. O'Dwyer stated that the cone could be easily placed in the larynx through the mouth and that the ringed grooving would keep it from slipping. By working the bellows, forcible inspiration could be maintained for any length of time necessary. During expiration the fingers should be withdrawn from the shielded opening. The apparatus was offered as presenting advantages for the treatment of opium-poisoning, and other cases requiring artificial respiration.

DR. WILLIAM OSLER, of Baltimore, read a paper on

"The Association of Congenital Wry-neck and Facial Hemiatrophy," reporting an illustrative case.

Dr. Charles G. Kerley, of New York (by invitation), read a paper on "The Application of Gavage in the Treatment of Uncontrollable Vomiting in Infants."

He advocated the use of a No. 13 Paine's adult nasal feeding-tube as preferable to the catheter that is used in gavage. The operation should be done quickly and predigested food only should be introduced into the stomach.

Dr. A. Seibert believed that in catarrhs of the stomach in babies, a similar condition exists in the mouth and throat. By the use of the tube, food would reach the stomach without receiving bacteria from the upper passages.

Dr. W. P. Northrup, of New York, read a paper on "Scorbutus in Children," illustrated by microscopic slides and drawings. Twenty-five typical cases of scorbutus in children were collected. Great stress was laid upon pain and swelling over the femora, with spongy gums, and the prompt recovery under proper diet as being almost diagnostic. Oranges proved most grateful to the patients.

Dr. Putnam reported that he had observed three cases of scorbutus in children. He thought that proprietary foods and condensed milk had much to do with its production.

Dr. Jacobi, of New York, stated that he had missed the definition of the disease scorbutus. He desired information as to whether bleeding from the gums should be considered a characteristic feature.

Dr. Northrup regarded subperiosteal hemorrhage with some swelling of the gums, with or without bleeding, as due to scurvy. The recovery under anti-scorbutic diet would confirm the diagnosis.

Dr. J. Lewis Smith, of New York, read a paper on "Scarlatinal Nephritis," in which he expressed the view of a microbic origin of the nephritis of scarlatina. At the same time, he cautioned against the risk of exposure to cold in the management of cases of scarlatina.

Dr. Seibert, of New York, believed that in many cases of acute nephritis in the course of scarlatina there was some cause for the disease. He had seen nephritis after acute attacks of tonsillitis and varicella. He advocated treating cases of scarlatina in well-ventilated rooms, even though cold.

Dr. Forchheimer, of Cincinnati, thought that the predisposing influence of scarlatinal nephritis was the virus, and that "catching cold" had little to do in causing the kidney complication.

The President expressed his belief that in many cases of scarlatina exposure to cold was productive of kidney disease.

Fourth Day—September 25th.

Dr. F. Forchheimer, of Cincinnati, read a paper on "The Etiology of Stomatitis Aphthosa," presenting the following conclusions:

Stomatitis is a disease produced by some form of deleterious material in the circulation, which may have its origin in various processes, bacterial or otherwise.

The action of this material is expended upon a nerve or nerves, upon a nerve-center or nerve-centers, and occasions an herpetic eruption that is the aphthous process.

A committee was appointed, consisting of Dr. F. Forchheimer and the President, to consider the nomenclature of the diseases of the mouth in children.

Dr. J. H. Fruitnight, of New York, read a paper entitled, "Perityphlitis in the Young," in which he summarized the treatment as follows:

In cases of chronic or subacute perityphlitis, without a tumor or with a small tumor, an expectant plan of treatment should be adopted. When there is a growing tumor, with or without evidences of suppuration, extraperitoneal incision or aspiration should be performed.

In cases of acute perityphlitis, with threatening symptoms, with tumor, and in subacute cases without tumor, exploratory incision (either peritoneal or intraperitoneal) should be made.

The officers elected for the following year were:

President.—Dr. William Osler, of Baltimore.

Vice-President.—Dr. J. M. Keating, of Philadelphia.

Secretary.—Dr. S. S. Adams, of Washington.

Treasurer.—Dr. C. W. Townsend, of Boston.

Recorder.—Dr. W. P. Watson, of Jersey City.

Dr. W. D. Booker, of Baltimore, was admitted to the Council.

The Society then adjourned, to meet in Boston in May, 1892.

CORRESPONDENCE.

EDITORIAL DEPENDENCE.

To the Editor of The Medical News,

Sir: Reading the excellent editorial in The Medical News of September 12th, on commercialism in relation to the medical press, calls to my mind an incident that in this connection I think is worth relating.

I was very much interested in a series of public meetings held in St. Louis last summer by a paranoic who posed as an evangelist. The interest from a medical standpoint attached to the fact that the phenomena of hypnotism were exhibited in many that attended the meetings.

The editor of a certain medical journal, having learned that I had made some study of the meetings, addressed me a very polite note asking me to prepare a paper upon the subject for his journal at an early date. At the same time he himself wrote a very sensible and vigorous editorial denouncing the meetings as exerting baneful effects upon the mental and moral health of the community.

I at once accepted the invitation and immediately set about writing the paper, so that it might appear at an early date. The next morning I received another note (also a polite one) from the editor, saying that he sincerely regretted that it was necessary to withdraw the invitation he had extended to me the day before, as the publishers of the journal were strongly averse to his editorial and desired that the journal have nothing further to say about the meetings. He assured me that personally he regretted that he would not be able to carry out his original design. *Homo alieni!*

I, however, continued the preparation of the paper, and when it was finished sent it to The Medical News, in which journal it was promptly published (September 27, 1890).

Theodore Diller.

NEWS ITEMS.

A Prize for a Work on Demography.—At the conclusion of the Seventh Congress of Hygiene and Demography it was announced that Dr. Körösi had offered a prize of 1500 francs ($300) for the best work on the subject of demography and its progress in the chief countries of Europe and the United States. Essays, which must be written in English, German, French, or Italian, must be sent by January 1, 1894, to the Permanent Committee of the Congress. The name of the author is to be sent with the essay, but in a sealed envelope. The paper will be examined by an international committee of five statisticians elected by the Permanent Committee, but not necessarily members of it. The prize will be awarded at the opening meeting of the next Congress of Hygiene and Demography at Budapesth.

Zeitschrift fur Orthopaedische Chirurgie Einschliesslich der Heilgymnastik und Massage is the name of a new periodical edited by Dr. Albert Hoffa, of Würzburg, the first number of which has just appeared. The name of the journal indicates the objects to which it will be devoted. It is intended to replace the *Centralblatt für Orthopädische Chirurgie*, hitherto under the editorial care of Dr. Beely, of Berlin. Four numbers (of which from four to six will appear annually) will constitute a volume.

The Fourth Italian Congress of Internal Medicine will be held at Rome, October 19, 20 and 21, 1891. Professor Baccelli will preside. Rossoni and Forlanini will read a paper on The Pathology and Treatment of Diseases of the Stomach; Albertoni and Queirolo will read a paper on The Pathology and Treatment of Auto-intoxications; Patella and Mya will read a paper on The Various Forms of Icterus.

Dr. J. W. S. Gouley will deliver a series of lectures on Diseases of the Urinary Apparatus, on Tuesdays, at 8.30 P.M., beginning October 6th, at the Mott Memorial Hall, 64 Madison Avenue, New York. These lectures, supplemented by clinics at the Bellevue Hospital, will be free to the profession and to students of medicine.

Prof. Maydl, of Vienna, has been elected Professor-Ordinary of Surgery at Prague.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM SEPTEMBER 15 TO OCTOBER 5, 1891.

VOLLUM, EDWARD P., *Colonel and Chief Medical Purveyor.*—Retirement from active service is announced.—*S. O. 211, A. G. O., Washington, D. C.*, September 11, 1891.

CRAMPTON, LOUIS W., *Assistant Surgeon.*—Is relieved from duty at Fort Sheridan, Ill., and ordered for duty at Fort Townsend, Washington, relieving James C. Worthington, Assistant Surgeon. Assistant Surgeon Worthington, on being relieved, is ordered to Fort Thomas, Ky., for duty at that station, relieving George M. Wells, Assistant Surgeon. Assistant Surgeon Wells, on being relieved from temporary duty at Fort Thomas, Ky., is ordered to San Carlos, Arizona, for duty.

KEAN, JEFFERSON R., *Assistant Surgeon.*—Granted leave of absence for three months, on surgeon's certificate of disability.

WELLS, GEORGE M., *Assistant Surgeon.*—Relieved from duty at Columbus Barracks, Ohio, and ordered to Fort Thomas, Ky., for temporary duty, relieving Henry I. Raymond, Assistant Surgeon. Assistant Surgeon Raymond, on being relieved, will report to the commanding officer Fort Robinson, Nebraska, for duty at that station.

DEWITT, THEODORE F., *Assistant Surgeon.*—Granted leave of absence for six months, on surgeon's certificate of disability.

KIMBALL, JAMES P., *Surgeon.*—Relieved from duty at Fort Supply, Indian Territory, and ordered to Fort Clark, Texas.

PATZKI, JULIUS, *Surgeon.*—Relieved from duty at Fort Huachuca, Arizona Territory, on expiration of present sick-leave, and ordered to Fort Supply, Indian Territory

ALEXANDER, CHARLES T., *Colonel and Chief Medical Purveyor.*—Relieved from the duties of Attending Surgeon and Examiner of Recruits in New York City, and assigned to the charge of the Medical Purveying Depot in that city.

FORWOOD, WILLIAM H., *Surgeon.*—Granted leave of absence for one month, on account of sickness.

EWING, CHARLES B., *Assistant Surgeon.*—Will continue on duty as Attending Surgeon and Examiner of Recruits at St. Louis, Mo.

CROSBY, WILLIAM D., *Assistant Surgeon.*—Relieved from duty at Fort Pembina, North Dakota, and ordered to Fort Missoula, Montana, for duty.

REED, WALTER, *Captain and Assistant Surgeon.*—Relieved from duty as Attending Surgeon and Examiner of Recruits at Baltimore, Md., and ordered to Fort Snelling, Minnesota, upon completion of his duties as a member of the Army Medical Board.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING OCTOBER 3, 1891.

HALL, J. H., *Surgeon.*—Placed on the Retired List, September 25, 1891.

TURNER, THOMAS J., *Medical Director.*—Placed on the Retired List, September 21, 1891.

BOYD, JOHN C., *Surgeon.*—Ordered to duty on the Naval Medical Examining Board.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U. S. MARINE-HOSPITAL SERVICE, FOR THE SIX WEEKS ENDING SEPTEMBER 19, 1891.

PURVIANCE, GEORGE, *Surgeon.*—Granted leave of absence for thirty days, August 22, 1891.

LONG, W. H., *Surgeon.*—Granted leave of absence for twenty-two days, August 18, 1891.

AUSTIN, H. W., *Surgeon.*—To proceed to Delaware Breakwater Quarantine Station, as Inspector, August 28, 1891. Granted leave of absence for thirty days, September 3, 1891.

GASSAWAY, J. M., *Surgeon.*—Granted leave of absence for ten days, September 19, 1891.

STONER, G. W., *Surgeon.*—Granted leave of absence for ten days, August 15, 1891.

CARTER, H. R., *Passed Assistant Surgeon.*—To proceed to Cape Charles Quarantine for temporary duty, August 27, 1891.

WHEELER, W. A., *Passed Assistant Surgeon.*—To proceed to Cape Charles Quarantine for temporary duty, August 27, 1891.

BANKS, C. E., *Passed Assistant Surgeon.*—Granted leave of absence for eleven days, September 3 and 9, 1891.

CARMICHAEL, D. A., *Passed Assistant Surgeon.*—Leave of absence extended thirty days, on account of sickness, September 10, 1891.

GLENNAN, A. H., *Passed Assistant Surgeon.*—Granted leave of absence for seven days, August 29, 1891.

GUITERAS, G. M., *Assistant Surgeon.*—Relieved from duty at San Francisco, Cal.; to proceed to New Orleans, La., for special duty, September 14, 1891.

WERTENBAKER, C. P., *Assistant Surgeon.*—Granted leave of absence for thirty days, September 10, 1891.

PERRY, J. C., *Assistant Surgeon.*—To proceed to Evansville, Ind., for temporary duty, September 18, 1891.

YOUNG, G. B., *Assistant Surgeon.*—Granted leave of absence for eight days, August 29, 1891. To proceed to Cairo, Ill., for temporary duty, September 15, 1891.

HOUGHTON, E. R., *Assistant Surgeon.*—To proceed to Vineyard Haven, Mass., for temporary duty, August 29, 1891. Granted leave of absence for sixty days and permission to go abroad, September 18, 1891.

PROMOTION.

GOODWIN, H. T., *Assistant Surgeon.*—Commissioned as Passed Assistant Surgeon September 18, 1891, to date from September 24, 1891.

ORIGINAL ARTICLES.

THE PATHOLOGY OF PERNICIOUS ANEMIA.[1]

BY J. P. CROZER GRIFFITH, M.D.,
CLINICAL PROFESSOR OF DISEASES OF CHILDREN IN THE UNIVERSITY OF PENNSYLVANIA,
AND
CHARLES W. BURR, M.D.,
OF PHILADELPHIA.

ALTHOUGH the causes and nature of the various affections that may be called forms of anemia are at present so obscure, yet, for purposes of study, some method of classification of these forms becomes almost a necessity. The difficulty of the subject is perhaps the reason for the number of classifications that have been proposed.

In a previous publication by one of us (*Cyclopedia of Diseases of Children*) anemia was defined as a diminution of the blood *in toto*, or of its albuminous material, blood-cells or hemoglobin, and a system of classification was suggested. We would now propose the following tabular scheme, which is somewhat modified from that in the publication referred to, and which we admit to be imperfect and only provisional:

- Anemia
  - Non-cytogenic
    - Hemolytic
      - Pernicious anemia.
      - Other toxic anemias.
      - Parasitic anemias [some forms].
    - Oligocythemic
      - Parasitic anemias [some forms].
      - Post-hemorrhagic anemia.
      - Anemia from loss of albumin.
      - Anemia from malnutrition.
  - Cytogenic
    - Oligochromemic
      - Chlorosis.
    - Leucocytic
      - Leukemia
        - Splenic.
        - Lymphatic.
        - Medullary.
    - Non-leucocytic
      - Simple constitutional anemia
      - Splenic anemia.
      - Lymphatic anemia.

The terms "primary" and "secondary" are best avoided altogether, as they have so frequently been misapplied. "Cytogenic" and "non-cytogenic," though not interchangeable with them, are certainly preferable.

In the light of all that has been written, one might be disposed to regard the foregoing tabular classification as arbitrary and unnatural; and the opinion might be, as it has been, advanced that there are few sharp lines of demarcation between the various forms of anemia. Thus, it has been maintained that chlorosis and pernicious anemia are closely allied, and several instances have been reported in which a transition from one disease to the other had taken place. Luzet has published a most striking instance of this apparent transformation. Leukemia was claimed by Wood twenty years ago to be nearly related to, or perhaps identical with, lymphatic anemia, and there have been a few cases reported, as, for example, by Mosler and Fleischer and Penzoldt, in which the latter disease seemed to be transformed into the former. Pernicious anemia has in some instances appeared to be closely allied to leukemia. Musser, for example, published a case in which the blood at one time indicated the existence of leukemia, though the condition later appeared to be one of pernicious anemia; and Leube and Fleischer have reported cases apparently the converse of this.

In spite of these seeming objections to the existence of different varieties of anemia as distinct and independent diseases, we lean to the opinion that at least many forms are entirely separate entities. We certainly take the ground held by the majority of physicians that chlorosis and pernicious anemia are widely separated from each other, and that the latter has certain peculiarities that sharply distinguish it from most other varieties.

Turning now more directly to the subject of this contribution—the pathology of pernicious anemia—only the briefest review can be given of some of the different theories that have been held. Various propositions have been advanced, which have met with no general acceptance. Among these are the claim of Klebs, Frankenhäuser, Eichhorst, and Petrone that a species of cercomonas, or that micrococci, exist in the blood. The belief of Kjellberg, that the disease is an infectious one, belongs to the same category. By far the majority of writers, however, have for years regarded pernicious anemia as a cytogenic disorder, a disturbance of the production of red blood-cells. Wood, in 1871, described the red condition of the marrow of the long bones, and Pepper thought that this might be the starting-point of the disease; while Cohnheim, a year later, was inclined to view this condition as the specific cause. According to this theory, the disease is a medullary anemia, or, as some have called it, a medullary form of Hodgkin's disease. The probability of the truth of this seemed great, since in cases of pernicious anemia no important post-mortem

[1] Read at the meeting of the Association of American Physicians in Washington, D. C., September 24, 1891.

anatomical changes could be found, except the hyperplastic alteration of the bone-marrow. Later, however, doubt began to arise as to whether the medullary changes had any etiological connection with the disease. Cases of pernicious anemia were described in which no such alteration existed, and Neumann, Litten and Orth, and others, found that this hyperplastic change takes place in other affections as well. Thus, in animals such a red marrow may be produced by repeated bleedings. (Bizzozero, Salvioli, Litten, Orth.) Eichhorst and others entertain the belief that in pernicious anemia the condition of the bone-marrow is purely secondary, the hyperplasia being only the evidence of the effort on the part of the hemogenetic bone-marrow to supply by excessive production the great lack of corpuscles in the circulation. Mott echoes the same sentiment.

Still another view has been maintained by several writers (Russell, Henry, Mackenzie, Purser), somewhat of a modification of that of the cytogenic nature of the disease. It is that the affection is an altered and imperfect, rather than insufficient, cytogenesis, by virtue of which the red blood-cells are so badly made that they break down very easily. Russell is perhaps the strongest supporter of this view, and reports a number of observations opposed to the theory (presently to be discussed) of the purely hemolytic nature of the disorder.

In this connection it may be stated that the alteration in shape of the corpuscles seen in pernicious anemia is not at all characteristic of the disease. We have seen this alteration well marked in cases of extreme anemia of other nature. The increase in the size of the corpuscles, and the occurrence of nucleated red blood-cells in the marrow and blood, are also very probably of a secondary nature, since they are not confined to this disease alone.

It would seem, then, that there is no change of the blood itself, or of the cytogenic tissues, that justifies the assumption that pernicious anemia is a cytogenic disorder. At any rate, it is not proved that there is any disturbance of blood-formation, and, by the laws of logic, the burden of proof rests upon those who assume that such a disturbance exists.

Omitting for the time the discussion of the published views that would ascribe at least some cases to the presence of bothriocephalus latus, or to atrophy of the gastric mucous membrane, we must, then, take up the consideration of the affection as one of a hemolytic nature. This theory has been brought into prominence by the able researches of Hunter, though his investigations were not the first upon the subject. Quincke, in 1876, in three cases of pernicious anemia, found a great increase in the amount of iron in the liver, and in 1877 Rosenstein confirmed this observation. Later, as a result of their studies, Quincke and Peters concluded that this increase is a constant and characteristic feature. Peters found that the increase might occur to a varying degree in other disorders. He attributed it, as did Quincke, to an excessive destruction of red blood-cells. Stahel, too, in a case of pernicious anemia, found a very great increase in the amount of iron in the liver, but none in the spleen.

These investigations seemed to be almost forgotten and their bearing not appreciated, until Hunter published his observations, which are too fresh in the minds of all to allow of more than the briefest reference. Hunter examined the viscera in a number of cases of pernicious anemia, and found a remarkable deposition of iron-pigment in the livers of all of them. The iron existed in a granular form within certain of the hepatic cells, viz., those of the outer and middle zones. In certain other diseases, as in cirrhosis of the liver, malaria, and chronic venous congestion, at times he found an increased amount of iron, but never to such a degree, and never exhibiting the peculiar arrangement that he regards as characteristic of pernicious anemia. He regarded the granular matter as a decomposed hemoglobin, since hemoglobin itself will not answer to the reactions for iron that he employed, and which will presently be described.

In some cases he was able to discover the same pigment in the cells of the renal convoluted tubules. He found no increase of iron in the spleen in any of his cases. He explains this on the ground that, though the hemoglobin is set free in the spleen or between it and the liver, it remains hemoglobin until it reaches the latter, and consequently gives no characteristic reaction for iron. The urine of his patients was of a dark color, due to the presence of a large amount of pathological urobilin, which is probably a still further alteration of hemoglobin, through the medium, however, of the bile-pigments. In one carefully-observed case the urine contained an increased amount of iron, together with two ptomaïnes, never produced except by the action of certain microörganisms.

He concludes, therefore, that pernicious anemia is the result of an excessive destruction of blood in the portal circulation, and that this destruction is due to the absorption from the alimentary tract of certain ptomaïnes produced, perhaps, by the action of microörganisms.

By a series of experiments upon animals he endeavored to produce artificially in them the symptoms and pathological appearances of the disease. For this purpose he introduced into the circulation various hemolytic substances; but found that though some of them were capable of producing hemoglobinuria, one, toluylendiamine, by its special action upon the blood and the liver, was efficient in producing a con-

dition of this organ identical with that seen in cases of pernicious anemia.

Other observers have since maintained the hemolytic nature of pernicious anemia, corroborating the statements made regarding the condition of the liver found post-mortem in this disease. It is true that, among these, Russell, while admitting the excessive hemolysis that takes place in the disease, believes, as we have said, that this depends upon a defective hemogenesis, and claims, from his study of the liver and spleen in forty-four cases of other disorders, that the excessive iron-reaction is not found in pernicious anemia alone. He has found an increase in the amount of iron in the spleen also in one case of pernicious anemia, as well as in a number of cases of other disorders. Mott seems to incline to the view that the disease depends upon the formation of some poison or ferment connected with microörganisms. In one case he found no iron in the spleen, though in another a deposition of pigment was observed.

Our own observations have little or nothing new to offer, and are of value only in so far as they may confirm or oppose the meager data as yet obtainable toward a more perfect understanding of this still very obscure subject. They have been confined, for the most part, to the question of the presence or absence of iron in the liver in pernicious anemia and in other diseases, particularly forms of anemia. We have also in progress a series of experiments upon animals; but, as they are not yet completed, the results will be reserved for future publication.

The reagents that we have employed have been those recommended by Hunter, Peters, and others. Sections of liver from specimens hardened in alcohol were, after washing in water, immersed for from five to fifteen minutes in a rather strong aqueous solution of potassium ferrocyanide; then, without washing, these were placed for an equal time in a weak aqueous solution of hydrochloric acid. The altered blood-pigment characteristic of pernicious anemia contains iron in a form that, treated in this way, develops the well-known Prussian-blue reaction, and becomes visible as granular matter of a blue color within the hepatic cells. The sections can now be passed through the necessary steps preparatory to preservation in balsam. The iron may also be rendered visible by immersing the sections in a freshly prepared solution of ammonium sulphide, by which means the sulphide of iron will be produced, and will appear as a heavy, black precipitate within the cells. We have, for the most part, used the treatment with potassium ferrocyanide.

The livers from three cases of pernicious anemia have been studied: the first from a patient of Dr. Morris J. Lewis, the second from a case occurring in the hospital of the University of Pennsylvania, and the third from a patient of Dr. J. H. Musser. It is sufficient here to say that examinations of the blood were made in all of them, and that, in this as in other respects, the symptoms were those characteristic of the disease. We shall confine ourselves to the condition of the liver with regard to the presence of iron.

Case I.—The hepatic cells of the outer and middle zones of the lobules were very full of iron-pigment, the amount constantly diminishing in the inner zone as the central vein was approached, so that in the greater number of the cells of this zone there was no appreciable amount of iron present. The iron was in the form of minute, irregularly-shaped granules. These, closely aggregated, seemed to form a continuous band running along the center of the irregular bands of hepatic cells. No pigment could be found in the capillary bloodvessels or bile-ducts. Besides the iron-pigment, a granular blood-pigment of a yellow color, such as is frequently visible in sections of liver, was discernible in parts of the sections, chiefly in the region nearest the central vein. The wall of the central vein was stained a blue-green color in the specimens treated with ferrocyanide, but no granular matter could be detected in it.

Case II.—The appearance of the liver was almost identical with that of the preceding case. In this case, too, there was noticeable the presence of a considerable amount of yellow pigment, chiefly in the inner zone of the lobule, and which was not affected by the potassium ferrocyanide.

Case III.—The condition of the blue-stained pigment in this case was almost identical with that in the preceding cases, though perhaps the amount was not so great.

The spleen was examined in the first case, and found to contain no increase in the amount of iron. The kidney in the first case exhibited a slight deposit of iron-pigment in the cells of the convoluted tubules. In the second case no such deposit could be found.

As check observations upon these, we have examined livers from a large number of cases of different diseases, making an especial effort to obtain preparations from patients affected by some disease attended with anemia. It would unnecessarily occupy time to detail the results of these investigations. It is sufficient in general to say that in not a single instance was the characteristic pigment found in amount at all comparable with that seen in pernicious anemia, nor did it present the characteristic arrangement. In most cases it was either entirely absent, or present in very small quantity. It is naturally to be expected that at least a small amount of pigment would normally be found in the liver, if, as supposed, this organ is the normal seat of blood destruction.

A few of the cases deserve a somewhat fuller reference.

1. In a case of cancer of the liver in which the connective tissue greatly preponderated, large masses of yellowish pigment were observed in carmine preparations. These were irregularly scattered throughout the sections, either among the liver-cells or in the connective tissue of the growth. They were apparently the result of hemorrhages. Sections treated with potassium ferrocyanide exhibited these masses stained blue.

2. On the other hand, a case of emphysema, with dilated heart, exhibited, as might be expected, considerable yellowish pigment, situated chiefly in the cells about the central vein. When treated with potassium ferrocyanide no iron reaction whatever was discoverable.

3. Another very interesting specimen was from a case of pernicious malaria, which had been under the care of Dr. George Dock, then of Galveston, Texas. The patient had presented evidences of excessive hemolysis occurring in the general circulation, as shown by the presence of hematuria, and probably of hemoglobinuria as well. The number of red blood-corpuscles was greatly diminished, and toward the end of life leucocytosis developed. The sections of liver in this case exhibited a large amount of deep-black granular pigment, the histological arrangement of which we shall not enter upon, further than to say that no such distribution was present as in cases of pernicious anemia. Sections of liver treated with potassium ferrocyanide exhibited a considerable amount of iron-pigment in the hepatic cells. The black pigment was entirely unaffected by the reagent.

Other cases might be cited in further illustration of the point we wish to emphasize, viz., that various sorts of pigment may occur in the liver, only some of which give the ferric reaction. The black pigment of the third case gave no such reaction. In each of the first two cases a yellowish pigment was visible in carmine preparations. When treated with the ferrocyanide this became blue in the first case, but was unaffected in the second. As a rule, the yellow pigment, seen so often in livers, does not react to the ferric test. In two of the cases of pernicious anemia reported, this pigment was present in the inner zone, and the blue iron-pigment in the outer and middle zones.

This variation in the nature of the pigments is in accord with the results of the researches of Neumann, who has shown that there are two forms of pigment in the body; the one, which he denominates "hemosiderin," giving an iron reaction, and the other without such reaction.

4. In connection with the last case, in which hemolysis occurred in the systemic circulation, sections from the liver of a case of Dr. B. C. Hirst's were of extreme interest. This was an instance of infectious hemoglobinemia of the newly born (often, though we think unfairly, called Winckel's disease). In this instance the liver exhibited no iron at all. The kidney exhibited a decided blue-green tinting of the convoluted tubules, and in some parts of the loops of Henle, though the Malpighian tufts and the collecting tubules were almost entirely free from it. Nowhere, however, was there any evidence of any actual deposition of granular pigment, even when high amplification was employed.

We have already stated that a deposition of granules was present in the kidney of the first case of pernicious anemia reported.

It would therefore appear from the third and fourth cases, the first of which was probably an instance of hemoglobinemia, and the second certainly so, that hemoglobin set free in the systemic circulation is not deposited in an altered form in the liver nor reaches the kidney in such a condition that it is found there in a characteristic granular form. On the other hand, in pernicious anemia hemoglobin set free in the portal circulation does become altered in a peculiar way in or before reaching the liver, so that it is either deposited there, or, if in too great excess to be disposed of entirely there, passes into the systemic circulation in such a changed form that it is not excreted by the kidney as hemoglobin, but as some other substance (pathological urobilin), while some of it is deposited in the renal cells in a chemical form similar to the granular matter in the liver. The reason for this difference between systemic and portal hemoglobinemia does not seem clear, nor can we explain why the spleen occasionally contains pigment in pernicious anemia and at other times not.

Besides conditions in which hemoglobinemia occurs, those disorders commonly ranked as "diseases of the blood" were of especial interest to us, particularly in view of the claims that have been advanced that they were closely allied to pernicious anemia, if not, indeed, capable of being transformed into it.

5. Sections of the liver from a typical case of lymphatic anemia were treated with potassium ferrocyanide. The lymphatic tissue present was entirely free from iron, as were also the hepatic cells, except those upon the extreme periphery of the lobules. Here a circle scarcely wider than the diameter of one or two cells exhibited a decided deposit of iron-pigment, though not at all comparable in amount to that seen in pernicious anemia.

6. Sections of the liver from a case of leukemia were entirely free from iron.

It appears therefore that there is no likeness between pernicious anemia and at least two of the cytogenic anemias.

7. Another interesting case exhibiting a marked increase of the amount of iron in the liver was a very unusual one of complicated ulcerative endocarditis, in which during the life of the patient there had been reason to believe that abnormal destruc-

tion of blood had been in process in the general circulation. Nevertheless the pigment was deposited in irregular foci entirely without reference to the structure of the lobules. The amount of iron by no means equalled that in the specimens from pernicious anemia.

Livers were examined from several cases of Bright's disease and of phthisis and no iron found. The liver also from a case of cancer of several of the abdominal viscera, in which the anemia and cachexia had been exceedingly well marked during life, failed to exhibit any iron. A case of anthrax and one of gumma of the liver were without iron.

Besides livers from persons not anemic, we have thus examined the organ in a number of varieties of anemia, viz., hemolytic anemia (pernicious anemia, pernicious malaria, infectious hemoglobinemia); anemia from loss of albumin (Bright's disease); anemia of malnutrition (cancer, phthisis); leukemia; lymphatic anemia. In no instance was iron found in the liver to the extent or with the characteristic distribution seen by us and reported by others in cases of pernicious anemia.

Conclusions.—Is it justifiable to consider pernicious anemia a distinct disease, and if so, what is its nature? Our experience seems to corroborate the view that there is in this disorder a deposition of iron in the liver unlike that observed in any other, and that—as a deduction from this and certain other conditions found — pernicious anemia is a form of hemolysis. It is therefore a non-cytogenic anemia. Whether there exists any defect in the formation of the corpuscles that predisposes to their destruction when the proper destructive agents are brought to bear, it is as yet impossible to determine. There seems to us no good reason for this assumption.

In one light it might be claimed that the disease, broadly considered, need not be a unity—that is to say, there is no reason why but a single poison should produce the characteristic destruction of blood. For example, a condition closely resembling pernicious anemia in the pathological changes may be produced in animals, as Hunter has shown, by the administration of certain hemolytic agents, such as toluylendiamine. This artificial disease is in one sense, in fact, a pernicious anemia. Pyrodin, also, has produced extreme anemia in man, as was shown by the case of Renvers, in which the number of red blood-cells per cubic millimeter fell in three days from 4,000,000 to 2,800,000.

The cases of pernicious anemia reported as cured by the expulsion of tapeworms probably owed their symptoms to the absorption from the intestine of some poisonous product produced by the worm. Had the patients died, it is at least possible that an increase of iron in the liver would have been found, particularly as the poison absorbed would have been acting within the portal circulation. These, too, might in a wide sense be called instances of pernicious anemia. Again, the cases of what seemed to be pernicious anemia due to atrophy of the gastric mucous membrane were probably the result of the absorption of some product of the decomposition of food in the stomach, since dilatation of the stomach, with the consequent putrefactive changes, is a characteristic symptom of atrophy of the gastric mucous lining. The anemia is certainly not one of inanition. A very analogous condition is that reported by H. Meyer, in which the most characteristic symptoms of pernicious anemia were promptly relieved by a single washing of the stomach, doubtless thereby removing some poisonous product of decomposition which was being absorbed and was destroying the blood-corpuscles.

As we have said, all these varying conditions might be considered instances of pernicious anemia taken in a broad sense of the term. Are we then to consider this disease as not having an individual existence on the ground that it may have these various causes? Should it possibly be looked upon as a symptomatic condition of these different affections? We think not. The fact of the existence of tapeworm or of gastrectasia with consequent fermentation or of other conditions *without* the symptoms of pernicious anemia, indicates that its peculiar complex of symptoms is not a necessary sequence to their existence. Pernicious anemia is rather to be looked upon as a distinct disease which may arise whenever some certain poison is present and is absorbed. When its symptoms are present in connection with the occurrence of tapeworm or other of the diseases referred to, it is to be regared as a *superadded* but distinct disease. In like manner, an apparent change of chlorosis into pernicious anemia would be no proof of the relationship of the two. There is no reason whatever why there should not be rarely engrafted upon chlorosis, or upon any other blood-affection, or in fact upon any disease whatever, a new condition, a distinct disease, which may chance to be a destruction of red blood-cells. This is very different from the view that has been expressed that pernicious anemia is a final stage of any other form of anemia.

Regarding chlorosis, we are believers in the distinctive character of the affection, and view it as in all probability of cytogenic origin—a fault in the proper formation of red blood-cells—as a result of which there is a deficiency in the amount of hemoglobin present. As there is no evidence of destruction of blood in chlorosis, one is almost forced to the conclusion that it is a disturbance of hemogenesis, whatever the cause of this disturbance may be.

If one wishes to refuse to pernicious anemia the

title of an independent disease because there may be more than one toxic agent that can act in exactly the same manner and produce similar symptoms, no absolute objection can be made. The disease is secondary in so far as it is hemolytic. In addition to the absorption of certain ptomaïnes, it is probable, and reasonable too, that pyrodin and certain other antipyretics, and possibly also other drugs capable of destroying blood, would produce the characteristic symptoms and post-mortem changes, should their action be continuously exerted for some time. It seems better, however, to regard all these cases, including the anemia seen in atrophy of the gastric tubules and accompanying bothriocephalus latus, as other and different forms of hemolytic anemia.

It would then be a just conclusion to regard pernicious anemia, in the ordinary sense of the term, as a truly independent affection, which may be defined as an extreme and increasing anemia, without marked loss of flesh, not directly secondary to any anatomical lesion or to the presence of any parasite, but probably due to the entrance into the portal circulation from the intestine of some certain hemolytic agent, the origin of which is unknown, but that is possibly of the nature of a ptomaïne.

A PLEA FOR THE ASSOCIATED CULTIVATION OF SPECIAL EXPERTNESS IN MEDICINE.[1]

By G. BETTON MASSEY, M.D.,
INSTRUCTOR IN ELECTRO-GYNECOLOGY IN THE PHILADELPHIA POLYCLINIC; PHYSICIAN TO THE HOWARD HOSPITAL, TO THE DISPENSARY FOR WOMEN, ETC.

GENTLEMEN: It is with much pleasure that I pronounce the American Electro-therapeutic Association an accomplished fact. Organized amidst many expressions of doubt on the part of occasional workers in electro-therapeutics, it has already met with a reception that insures a career of active usefulness in the near future, and has enrolled a membership with which it is an honor to be associated. It is of this infant organization that I wish to speak to you, of its reason for being, and of its responsibilities, as an illustration of an important means of advancing the sum of human happiness by exalting the skill of practical workers in a certain field of medicine.

Among the special societies of the day none occupies the peculiar position of an electro-therapeutic association. None other is devoted to the study of a single therapeutic agent, or has a membership embracing workers in so considerable a number of specialties. Narrow in one sense, it is in another sense nearly as broad as medicine itself, since there are but few departments of medical work unrepresented in our present program.

But such an association as this differs in a more important particular from other special societies. Whilst, like them, composed of students of a certain subject, the members of this Association are not exclusively devoted to the questions to be considered here. They are rather a company of special workers in diverse departments, seeking greater expertness in the administration of a certain therapeutic force. That the progress of the healing art as a whole has made it incumbent on certain of its practitioners to devote special study to this one therapeutic force, is a sign that medical art is partaking fully in the general advance of science, which demands the services of experts in every field. At the very inception of this Association I therefore wish to lay stress upon a proper idea of its reason for existence. Let no one suppose that we are here to uphold or study any exclusive system of treating disease. We are here merely as experts and students desiring greater knowledge of a favorite art, and I trust that you will debar from membership any person who does not give adherence to medical knowledge as a whole, and make proper use of any and all agencies of value in the cure of the sick.

A necessity of the times, as evidenced in recent changes in medical education, is the enforcement of a broader culture among physicians. There is no doubt that this will tend to increase the membership of special scientific associations, but it must not be forgotten that these organizations themselves arise from a more peremptory assertion of the natural law of supply and demand. There is always a vast difference between the merely cultured man and the expert: the one delights us, but to the other we turn for the advancement of human knowledge and for real help in the crises of life. As the community increases in intelligence this seeking after experts will doubtless become more pronounced in all departments of human service of man to man above the mechanical work of the common laborer, and we may well conclude that the healing art will partake fully of the benefits of this natural selection. A demand for experts creates a demand for expert training, an educational thoroughness that is at present well known to be impossible in our medical colleges. To meet this emergency there have, fortunately, grown up of late two agencies: the one, the post-graduate college, to teach ordinary skill; the other, the special society, which bears to yet unconquered disease the relation of a well-disciplined army to the borders of a hostile and unexplored country. Thoughtless men neglect both, but the wise see in such agencies the means of advancing personal knowledge of the practical needs of their work. It is to be hoped that their establishment

[1] Being the Presidential Address delivered at the first annual meeting of the American Electro-therapeutic Association, held in Philadelphia, September 24, 25, and 26, 1891.

will quicken an evolutionary process in our profession that will finally develop it into an ideal organization of skilled interdependent workers; where each member, profoundly cultured in the universal sciences of medicine, will yet confine his work to that branch in which he is skilled. Such a specialism in parts and members is Nature's ever-present pattern for our admonition and imitation. When such a time has arrived, the fortunate objects of our professional care will receive that highest skill to which they are in justice entitled, and which at the present moment they rarely receive.

In this hoped-for Utopia of professional conscientiousness, skilfulness, and modesty, I am sure it will be impossible to duplicate the position of a recent correspondent, whose apparently careful and exhaustive article on the electrical treatment of uterine fibroids in a recent journal led me to request him to discuss the subject at this meeting. He replied that he knew almost nothing about electro-therapeutics—a fact that I had already suspected. So remarkable an admission of ignorance from a person assuming the position of trying and judging, causes one to wonder if he had been equally frank with the thirty or forty patients mentioned in the paper before undertaking their treatment. Well might we beg a modern addition to the ancient Hippocratic oath—in which the medical man swore not to "cut for stone"—an addition that would compel the non-expert to forever refrain from assuming responsibilities for which his training has been insufficient, and that would have rendered impossible that recent crop of jacks-of-all-trades who have "tried electricity." Of all the enemies of scientific research in electro-therapeutics, these are the worst. Not even the pure quacks do the harm of these Pharisees, who, when their patients demand it, blunderingly attempt to use a remedy in private, and publicly condemn it on the strength of such evidence. Such mistaken attempts at medical omnipotence should be frowned upon as savoring of a crime toward both the patient and the remedy.

The organization of a national Electro-therapeutic Association crowns the full emancipation of this remedy from the thraldom of quackery. Neglected by the profession in the years that elapsed between the memorable medical experiments of Franklin in this city and the discovery of the dynamo, the marvellous triumphs of electrical engineers have at last aroused medical men to the need of discarding ideas, methods, and appliances that preceded the electrical new-world discovered some fifteen years ago. The assumption of new methods in electro-therapy has been extremely slow as compared with the industrial revolution that has already altered the face of civilized communities, but it is to be hoped that this body will be a powerful stimulus to the spread of scientific work in America.

Science, however, is but another name for truth, and in touching upon the objects of an Association for the study of a force so well harnessed by natural law as electricity, it is evident that in our discussions truth must ever be held as paramount. Armed with laws that unlock the hidden power of this force over certain diseases, we are also equipped to demonstrate its utter uselessness in others by the application of an agnosticism that refuses to believe anything unless proven. But in clearing away the rubbish of unproved statements that make up so much of our archaic electro-therapeutic literature, we shall by no means weed out the entire field of so-called medical empiricism. It is not alone in electro-therapy that the careless dicta of professional book-writers have told us that such and such an agent is good for such and such a disease, without specifying the conditions that in actual practice are necessary to save us from failure. Read any classical work on general therapeutics that is ten years old, and see the blind empiricism from which all therapeutics has been evolved. There should be no nobler work for this Association than sifting the ancient claims for electricity, particularly in certain diseases of the nervous system, and establishing either their falsity or the conditions under which they are true. All remedial agencies are environed with limitations that vary with the dose used, the condition of the patient, etc., and this is particularly true of the one under consideration, which, in turn, may be a calmant, a stimulant, an absorbent, a solvent, and a destructive agent. Here a hundred possible variations must be scanned to get the possible road to success, and hence this society is an eminently technical one. The broad question of the value of electricity in a certain disease should be subordinated here to exact data of the kind of current used, the dose, the duration and frequency of treatment, and the nature and position of the electrodes. All these should be specified before a claim is made that this agent is worthless in a given disease, since a different combination of the same factors and conditions might have led to success. Similarly, the conditions giving rise to the successful treatment of a disease should be specified with equal minuteness in order that others may find it possible to verify and duplicate our results.

It is for such work that the American Electro-therapeutic Association is needed, and badly needed. I do not decry the presentation of electrical papers to our various general and special societies, but it is in the nature of such presentations that they must assume the polemical attitude of enthusiastic indorsement or wholesale condemnation of general facts—must deal in glittering gener-

alities—in order to be other than tedious to their audiences. Such papers do little to advance our knowledge of a special subject, and the speakers that follow are rarely capable of intelligently discussing those whys and wherefores of success and failure that I trust you will at these meetings bring into prominence.

Among the questions that demand this critical investigation may be mentioned the whole subject of the use of electricity in organic nervous diseases and in the neuroses. We are here handicapped, of course, by a still imperfect knowledge of many pathological conditions underlying these diseases, yet I think it is even now possible to make a broad division of the electro-therapeutics of nervous diseases into two groups, the one acting by transferred physiological processes through the agency of the spinal and sympathetic systems, and the other acting by virtue of a direct passage of lines of flow through—or by a polarization of—the primary or secondary seats of the disease. The indirect method is, unfortunately, the more common, since we are restricted to it frequently by the deep situation of the diseased areas, and in its various applications we are limited in progress by the limitations of these physiological carriers of our remedy. We are here in much the same position as in prescribing drugs, whose action is generally limited by the circuitous routes of absorption and circulation. It is doubtless in the method of direct action that electricity will yet make its greatest advances in the treatment of nervous diseases: a method that involves the possibility of concentrating a sufficient density of lines of force through a diseased area to accomplish an alteration in its nutritive condition. This is yet an almost virgin field in neurology, depending somewhat upon improved methods of conducting efficient currents through the dermic surface; and, in estimating the possible future value of strong currents thus scientifically conducted to the actual seats of disease, I can conceive of but one organic basis of disease as absolutely and at all times unpromising and resistant, namely, that due to living germs.

Of the work before you in considering the value of electricity in gynecology I need not speak at length. This is regarded as a most important question in every gynecological society in the world, and while we are fully justified in considering its relative value as compared with other means, we shall have a greater opportunity to discuss the many technical questions that belong to the subject. Here, indeed, is material alone sufficient for a society. The exact methods used by men of large experience in the various diseases of women are living questions that come home with force to anyone who essays this work. Such things are rarely well shown in books because of the changing extent of our yet imperfect knowledge. Owing to the many possibilities of direct treatment in gynecology we have, nevertheless, already accumulated a most respectable series of exact therapeutic facts, with many useful rules deducible from them, and in the great activity now characterizing this branch of electro-therapeutics an almost daily advance in our knowledge is inevitable. It is in this department of diseases of women that electricity as a remedy has encountered its first real and bitter opposition from non-users in the profession, but we should remember that here its greatest value as a curative agent is becoming conspicuous, for "the blood of martyrs is the seed of the faith." To its good work of restoring health and function by combating disease processes has been added the labor of combating unwise surgery, which, in a laudable effort to perfect a useful technique, has sacrificed thousands of patients and parts of patients on the altar of harsh experiment.

Among other branches of the work great interest attaches also to the electro-therapeutics of visceral and circulatory diseases; of dermatology; of strictured canals and orifices; and of the naso-pharynx. Each of these questions will be infinitely better understood when discussed by experts, and cannot fail to be placed on a higher plane of scientific exactitude by each one of our annual gatherings.

As important accessories to these advancements in our ability to cure and control disease, certain questions of detail common to all this work demand our attention. This Association should take action on the important matter of securing a uniform and reliable calibration of our milliampère-meters. Many of the instruments supplied to the profession are improperly graduated, and others soon fail to read correctly through imperfect construction. This is surely a matter of greater importance than the correctness of the scales used in trade, over which the State wisely maintains a supervision. In the absence of government assistance in verifying our instruments some practicable substitute should be devised. Our faradic batteries are also yet far from perfect, besides being devoid of intelligent means of graduation, and I trust that you will take early steps to bring this somewhat old-fashioned instrument up to the high character demanded by modern work.

Such, in briefest language, are some of the reasons why special workers should meet in occasional conclave. To sufferers from the affections coming under our care this meeting is fraught with high consequences. Unless we can go back to them with an added power over disease our coming here is bereft of its highest value, for in the presence of human suffering we can recognize utility alone as our measure of results.

SYPHILITIC SPONDYLITIS IN CHILDREN.[1]

By JOHN RIDLON, M.D.,
OF NEW YORK.

On October 15, 1886, before the Section on Orthopedic Surgery of the New York Academy of Medicine, I read a paper entitled "Syphilitic Joint-disease in Children," and exhibited patients with the disease located at the ankle, knee, hip, wrist, and finger-joints, and in the spine. All cases had been treated by immobilization, and each case had been experimentally observed for varying periods with and without anti-syphilitic medication until the diagnosis had appeared to me to be conclusive, when each was finally placed upon the treatment that was continued until its final cure.

Notwithstanding the fact that these cases differed somewhat in their clinical aspects from ordinary tuberculous disease when located in the various joints; that nearly all gave a clear history of syphilis in the parents, and at some time in their course had presented other well-recognized syphilitic lesions; that while under the anti-syphilitic medication all had shown marked improvement, which they had failed to show under immobilization alone—notwithstanding these things, no one of the orthopedic surgeons present was willing to admit that the joint-lesions presented were syphilitic, but insisted that they were all of the ordinary tuberculous variety. One eminent man went so far as to say that in his extended experience in the treatment of chronic joint-disease he had frequently observed the curative effects of mercury upon tuberculosis. Indeed, so unanimous and positive was the opinion among my colleagues that there was no such thing as syphilitic joint-disease that I had not the temerity to publish my paper. However, five more years of observation have not only confirmed the views that I then held, but I have been led to believe that syphilitic joint-disease is of much more frequent occurrence than I then supposed, and I have ventured once more to bring forward a portion of the subject for consideration.

All of my observations have been among children in whom there was no evidence of a primary syphilitic lesion, and in very many I have sooner or later been able to trace a syphilitic taint in one or both parents; on this alone I have felt justified in assuming that the disease was inherited. It should be known that no microscopic examination has been made by me to demonstrate the presence of the syphilitic bacillus or the absence of the tubercle bacillus, and that I do not profess to know what relation exists between tuberculosis and syphilis in the second and third generation. Clinically, however, there can be no doubt of their relation. Ricord and Maisonneuve taught that syphilis, especially in the tertiary form, could be transmitted to the offspring as scrofula, phthisis, and rhachitis; and Bumstead and Taylor (*Venereal Diseases*, fourth revised edition, p. 735) say: "Syphilis is generally transmitted only to the second generation; exceptionally, in case of excessive activity of the disease in the first inheritor, it may appear in the third generation."

The diagnosis of syphilitic joint-disease in a child does not necessarily imply an accusation of one or both parents, for, if "one-third of all children procreated of syphilitic parents are dead-born, and of those born living 24 per cent. die within the first six months of life," and if "in case of infection of both parents the disease is likely to be transmitted in an extreme form, resulting in death of the fetus, or in the early manifestation of symptoms," it would not be unfair to conclude that some cases of syphilitic joint-disease in children that appear as late as from the tenth to the fifteenth year, like some other syphilitic symptoms, may have been transmitted from the original sin of a grandparent, the parent having escaped, or at least having never been conscious of any syphilitic manifestation. Bearing upon this, let me again quote from Bumstead and Taylor: "These cases of late development are rather rare, although we have seen fully two dozen in which there were such lesions at the third, sixth, eighth, twelfth, fifteenth and twentieth years. . . . . Besides the cutaneous and visceral lesions of the first year or two, other syphilitic affections are frequently observed. In many cases the diaphyso-epiphyseal lesions of the bones appear during uterine life, and run their course in the early months of the disease, possibly relapsing at a later period; or they may appear for the first time during the first year of life. From the fourth up to the twentieth year the shafts of the bones may be affected by periostitis, and joint-affections often occur. . . . . Dactylitis is usually observed in very young children; it may also occur as late as the twentieth year." Notwithstanding this teaching, and that of numerous English, French and German observers, syphilitic joint-disease in children has no place in the orthopedic literature of this country.

One gentleman, who had the opportunity of examining all of the patients reported upon in my former paper, said that he did not consider any of them as cases of syphilitic joint-disease, but as "tubercular joint-disease modified by inherited syphilis." It has seemed to me that it would be a more correct expression of the condition, provided the tubercle bacillus can be demonstrated to be present in these lesions, to call them syphilitic joint-disease modified by tuberculous infection. It

[1] Read before the American Orthopedic Association, at Washington, D. C., September 24, 1891.

is well recognized that traumatic joint-affections, if neglected in treatment and prolonged by use, readily become infected with the tubercle bacillus; and it may not be an unfair assumption to claim that the bone and joint-lesions due to syphilis in the progenitors, when neglected or refused remedial medication, also readily become the seat of tuberculous infection. The symptoms, prognosis, and treatment of these cases are quite different from the cases primarily traumatic or tubercular.

The following case, which is not an imaginary one, is instructive:

A young child, of a clean mother, but whose father at the time of the conception was suffering from tertiary syphilis, developed chronic disease of a joint; he was treated with anti-syphilitic remedies and kept in bed, but without mechanical restraint; and recovered after a few months, with a joint normal in all its appearances and functions. Subsequently he developed a chronic disease in another joint, which presently exhibited the same symptoms and signs that had been observed in the former joint-affection. He was now subjected to mechanical treatment without medication. An abscess appeared and was allowed to open spontaneously. Once or twice a fortnight this sinus was exposed for some time in a room crowded with patients suffering from tuberculous lesions; it was washed with water from a dirty tin basin that had been used for years by hundreds of patients for washing away the discharge from tuberculous sinuses, and it was then dressed with a pad of common oakum taken from an open box, in which it had lain for months, exposed in this room daily crowded for three or four hours with patients dripping with tuberculous pus. At the end of some months of this treatment the surgeon in charge, as he afterward told me, confirmed his diagnosis of tuberculous joint-disease by finding tubercle bacilli in the discharge from this patient's sinus. The patient continued for more than two years under the most approved mechanical treatment without apparent improvement in the condition of the joint or diminution in the amount of discharge from the sinus. Then, under a comparatively short course of mercury and iodide of potash, the sinus closed and all symptoms of joint-disease disappeared—leaving behind, however, a deformed and stiff joint.

Syphilitic spondylitis differs in no way from syphilitic joint-disease located elsewhere, except as it is modified by its peculiar surroundings. In the superficial joints, where the infiltration of the soft parts and bone can be readily seen and felt, the onset of the disease is very slow, and months may pass before pain is complained of or disability becomes serious; but in the spine, where the lesion is located in and about the anterior surface of the vertebral bodies, far beyond sight and touch, the slow advance of the early symptoms escapes recognition and the onset usually appears to be comparatively rapid. On any motion the distant pain is complained of, and sometimes within a few days the patient is unable to stand without support. If located in the dorsal region, the kyphosis soon appears with a sharp angle, formed of but one or two spinous processes, and with a long sweeping curve above and below. In the lumbar region, the kyphosis is slow to appear, often not appearing until marked psoas-contraction can be made out, and perhaps not until an abscess has formed; but lordosis is an early and well-marked symptom.

When the disease is once established, it seems to follow the rule of all syphilitic lesions, and is a cumulative process rather than one of degeneration—it is a hyperplasia rather than a molecular disintegration. When a certain point has been reached, resolution takes place, or the new tissue dies and an abscess rapidly forms. If the abscess can be evacuated under favorable conditions the disease often goes on to a rapid and complete recovery. Abscesses that are not within reach will almost invariably undergo rapid resolution when, under the influence of the mercurials, the patient is once well.

If no syphilitic history can be obtained from either parent, and if it cannot reasonably be suspected, an examination of the spine alone may not be sufficient to warrant the diagnosis of syphilis. Other things must then be taken into consideration; for, although a syphilitic spine may, and no doubt does, often exist without there being or having been other syphilitic lesions, the presence of such lesions is evidence of such value that the patient should always be carefully examined.

Spondylitis in very young children, that is to say, under three years of age, and spondylitis associated with chronic disease of some other joint, or in another portion of the spine separated by a healthy area, is in my experience more often syphilitic than tuberculous. Such cases always repay a careful examination and a strict watch for the appearance of other syphilitic manifestations, namely, nasal catarrh with the formation of reddish-brown crusts, suppurating otitis, corneal opacities, interstitial keratitis, Hutchinson's teeth, periostitis, cutaneous eruptions, and sores about the anus and genitals. In my experience, the most common associated symptoms have been the bone and joint-lesions at some distant point, and the least common have been the skin-eruptions.

The treatment of syphilitic spondylitis should be both mechanical and medicinal; but the mechanical plays by far the less important part, and rest in bed or on some form of portable bed will be found to be more demanded than braces. Rest in the recumbent posture during the painful stage is absolutely essential, while the application of specially devised apparatus may be looked upon more in the light of a luxury than a necessity. The medicinal

treatment consists of mercury and iodine. Large doses should be used; if the stomach will tolerate it, as much as one-thirteth to one-twenty-fourth of a grain of the bichloride or biniodide, with from five to forty grains of potassium iodide three or four times a day. If the stomach proves irritable, mercury with chalk in from three- to five-grain doses, with inunctions of blue ointment, are advisable. Tincture of iodine in from one- to ten-drop doses may be given. It will be found that these children usually bear these medicines in as large doses and as well as do adults.

CASE OF ABSCESS OF LUNG; OPERATION; RECOVERY; REMARKS.[1]

By FRANCIS HUBER, M.D.,
of New York.

As a text for the remarks to follow, the history of the case is given in brief:

Benj. J., four years old, had been ill about four weeks when first seen in October, 1888. He was troubled with exacerbations of fever, irregular chills, and a distressing cough; had lost flesh and strength, growing pale and waxy in looks. The physical examination was negative, with the exception of an area of flatness, with distinct bronchial breathing in the right infra-clavicular and mammary region. Exploratory puncture brought pus, and the diagnosis of localized empyema was made. At the operation (incision with drainage) pleural adhesions were found and the pus was discovered to be in the substance of the lung. The cavity gradually contracted and a small fistula remained, which closed about ten months from the onset of the disease.

The exploring syringe readily detected pus on the day prior to the operation. Rather unwisely, the needle was removed and the incision made. When the pleura was opened, the needle was again inserted, and it was only after repeated punctures that the site of the suppurating process was rediscovered. A severe pneumonia of the upper lobe (laterally and posteriorly) resulted, no doubt caused by the multiple punctures. In another case I shall certainly leave the needle in as a guide. Gentle irrigation of the cavity or of the fistula later on was not followed by any bad effects; if forcible injections were resorted to, a severe paroxsymal cough would follow, to terminate when the injected fluid had been expectorated, the fluid having entered a bronchial tube.

Although abscesses of the lung secondary to tuberculosis, pyemia, metastatic processes, or traumatic in character, are by no means infrequent, the simple non-tuberculous and non-metastatic varieties are but rarely met with. They present themselves in one of four forms. In the first variety the symptoms are obscure and the diagnosis is only made when the abscess ruptures into a bronchus or the pus is discharged externally through the integument. In the second class the symptoms resemble those of pleurisy with effusion; in the third class, those of tuberculosis; the fourth variety is generally associated with broncho-pneumonia. The affection is at times met with in children in a debilitated condition, living under poor hygienic surroundings. Meigs and Pepper believe the trouble to be of frequent occurrence, a sequel to the third stage of pneumonia, while Gerhardt, Henoch, Eustace Smith, and others, teach the contrary. The early recognition of the disease is difficult, for the disorder is usually secondary to pneumonia; the occurrence of chills, sweating, and increased vital depression ought to put one on his guard. A sudden expectoration of pus, with the rapid formation of a cavity in a portion of the lung previously consolidated, is characteristic of the rupture of a pulmonary abscess.

Abscesses may be solitary, of greater or less size; may be multiple and disseminated, superficial or deeply seated. The smaller may coalesce to form larger abscesses. The process may run an acute course or become chronic; it may occur coincidently with the original disease or manifest itself later, the pulmonary tissue remaining consolidated, resolution not having taken place. The walls may be sharply defined or the suppurating process may gradually be lost in the normal lung-structure. Perforation may occur into a bronchus or externally through the integument; the pleura or some adjoining organ may be invaded. Or the abscess may become encysted, undergo calcification, caseous degeneration, or become infiltrated with tubercles. In some cases the entire lung has been destroyed and converted into a large abscess-cavity.

The physical signs are not characteristic; before rupture occurs the parts are consolidated. A sudden more or less copious expectoration of pus in the progress of a pneumonia is due to the bursting of a pulmonary abscess. We now get the physical signs of a cavity in a portion of the lung previously infiltrated.

As to differential diagnosis: In gangrene the odor of the breath is fetid, the expectoration being green, fetid, and penetrating. Localized empyema may be excluded by the absence of a history of former pleurisies. In empyema discharging through the lung, the quantity of pus expectorated is large and the physical signs reveal fluid in the pleural sac. When hepatic abscesses discharge through the bronchi, the expectoration is copious, dirty-brown, and paroxysmal. In doubtful cases of tuberculous character, the presence of tubercle bacilli will establish the diagnosis.

Treatment is symptomatic, and consists in the use of stimulants, tonics, and antiseptic inhalations.

[1] Abstract of a paper read before the American Pediatric Society, Washington, September 23, 1891.

The exhaustion may be counteracted, and infection prevented by proper incision and drainage.

In conclusion, the rules enunciated by Drs. Spillman and Haushalter are presented for our guidance:

1. Before operation, the position of the abscess must be determined as accurately as possible, and especially by exploratory puncture.

2. As a rule, a pulmonary abscess should not be opened during the course of an acute pneumonia.

3. Before the abscess is opened, it is well to excite pleuritic adhesions, if these do not already exist. This should be done by resection of a rib and suture of the two pleural surfaces, or by means of the actual cautery.

4. The abscess is best reached by resecting a rib and piercing the lung with a thermo-cautery.

5. Free drainage is essential; antiseptic injections are best avoided, dry dressings being preferable.

CLINICAL MEMORANDUM.

GUNSHOT WOUND OF THE LEFT CUNEUS, WITH RIGHT HOMONYMOUS HEMIANOPSIA.[1]

BY J. T. ESKRIDGE, M.D.,
OF DENVER, COL.

E. A., a well-developed colored man, was shot in the left occipital region of the head in the latter part of May, 1890. From the measurements taken on the scalp, the ball, of thirty-eight caliber, entered the brain two and a half inches anterior to the occipital protuberance and half an inch to the left of the median line. The ball was extracted a few hours after the infliction of the wound, by enlarging the opening in the bone. The ball was found about half an inch below the cortical substance of the brain. The man was considerably depressed by the shock, but apparently did well for two or three days subsequent to the operation. I examined him on the second day after the ball was extracted. Besides a sense of prostration of which he complained, and a tendency to sleep, there was nothing in his condition to interfere with a satisfactory examination. I found no rigidity, paresis, or paralysis, of any of the muscles. The pupils were slightly dilated, but responded well to light and accommodation. There was no difficulty in moving the eyes in all directions. The plantar and patellar reflexes were very feeble, but a little more marked on the left than on the right side. The cremasteric and abdominal reflexes were abolished on the right side, and were feeble on the left. Tactile, muscular, temperature, and pressure senses, were normal. Taste, hearing, and smell seemed to be well preserved, and equal on the two sides. The acuteness of vision was not tested, but the fields were well preserved on the left side of each eye, and totally blind up to the median line on the right. The fundus of each eye appeared nearly normal, excepting a possible slight hyperemia of the papilla. His mind appeared to be dull and to act slowly; but on arousing him from his apathetic condition he answered questions fairly satisfactorily, and seemed to appreciate what was said to him. Concentrated attention could be maintained by him only for a few seconds, from a feeling of exhaustion. Temperature 100°, pulse 90, respiration 28.

The day after the examination he was more stupid, and was inclined to sleep constantly, and on the following day he was totally unconscious, with a temperature of 102°. He died on the fifth day.

The autopsy, under the direction of the coroner, was made eighteen hours after death. On removing the surgeon's dressings, not a drop of pus was found. The opening in the skull, enlarged by the trephine, was one inch in diameter, and was two inches anterior to a point opposite the occipital protuberance, and three-fourths of an inch to the left of the median line. The membranes of the brain, both the dura and the pia, were engorged with blood, but no pus was found. There was a hole in the brain-substance two inches in diameter. Posteriorly, it extended to within one and a half inches of the tip of the occipital lobe. On the median surface of the hemisphere there was a thin layer of brain-substance, apparently about one-eighth of an inch in thickness posteriorly, and from one-quarter to three-eighths, anteriorly. This was not softened or broken down anteriorly, but at its posterior portion lacked normal consistence. The destroyed brain-substance reached anteriorly a point one inch posterior to the upper end of the fissure of Rolando.

Laterally, over the convex surface of the brain, the wound reached to a point one and a half inches distant from the angular gyrus, but the white matter of the brain was softened to a point almost beneath the gyrus angularis. The cuneus was as completely destroyed as it would have been possible for an expert physiological experiment to have effected without interfering with other portions of the brain. The wound did not extend down to the tentorium cerebelli. The great ganglia and the base of the brain presented a normal appearance.

CURRENT LITERATURE.

TREATMENT OF HEPATIC COLIC WITH OLIVE OIL.

VILLEMIN (*Bull. Gén. de Thérap.*, No. 14, 1891) admits that while clinically the good effects of olive oil in the treatment of hepatic colic are recognized, no explanation of the mode of action yet proposed is satisfactory.

1. *The direct action of the oil upon the calculi.* It has been said that the oil, entering the gall-bladder, softened the stones, which were then driven into the intestine by muscular contractions of the wall of the bladder. In fact, in several animals killed after a quantity of olive oil, pure or colored, proportionate to the weight of the animal, had, by means of a tube, been introduced into the stomach, Chauffeard and Dupré recovered the oil in the stomach and intestine, and never beyond the ampulla of Vater in the duodenum. Further, if a cholesterin calculus be immersed in olive oil it remains unaltered, without change in aspect or consistency.

2. *The cholagogue action of the oil.* Most clinicians

admit that it is impossible to disintegrate or dissolve biliary calculi *in situ*; by the use of cholagogue remedies and of olive oil it is hoped to accomplish the arrest of an attack of hepatic colic by hastening the descent of the stone by increasing the secretion of bile and causing its expulsion into the intestine. To ascertain whether or not the oil possessed the property of increasing the biliary secretion, numerous experiments have been performed upon animals in which biliary fistulæ had been established. Schmidt and Bidder noticed in cats fed upon a diet of fat a diminution in the quantity of bile discharged. Rosenberg, however, believing that bile is necessary for the emulsification and reabsorption of fats, thought that the ingestion of a large quantity of oil should cause an abundant secretion of bile. In dogs that received in addition to their usual nourishment about 100 grams of olive oil, he noticed at the end of thirty or forty-five minutes, sometimes only after two hours, an increase in the biliary secretion, which became considerable toward the third or fourth hour. With other cholagogues he failed to obtain effects comparable in duration or intensity to those produced by the oil. He noticed, moreover, that, under these conditions, the bile was diminished in consistency, as a result of which the precipitation of cholesterin seemed to be retarded. In the second place a more abundant flow of bile would result in a purely mechanical action. In truth, many observers attribute a preponderant role in the formation of calculi to a stagnation of the bile. It has, however, been shown that while the cholagogue action of drugs is very efficacious in preventing hepatic colic, these are without effect in arresting an attack of existing colic. In the case of the oil the atack is arrested in a few minutes, whilst the cholagogue action never follows before a half-hour.

3. *Reflex action.* There is yet the possibility of reflex action to explain the mode of action of the oil. Whatever may cause the engagement of the calculus in the cystic duct, it can descend even to the duodenum without difficulty or injury. If the stone is small it is carried off with the bile; if it is larger, it is propelled by the contractions of the muscular fibers of the duct. It has been demonstrated that attacks of hepatic colic are dependent upon reflex spasm of the walls of the gall-bladder, or of the cystic or common duct. To relieve such an attack a remedy should overcome the spasm upon which the pain depends. It is, therefore, believed, that in the first place the oil, by determining a greater fluidity and abundance of the bile, may prevent the formation of calculi, and when an attack of hepatic colic has been induced the oil may by a reflex action arrest both the spasm of the biliary passages as well as the pain occasioned by this spasm; subsequently the cholagogue action of the oil may favor the descent of the calculus into the intestine.

The mode of employment of the oil varies with the end to be accomplished. When an impending attack of hepatic colic is to be averted, the oil is best administered in the evening, at as long an interval as possible after the meal, in order not to interfere with digestion. A dose of an ounce and a half, repeated on several successive days, will generally be sufficient to abort an attack. When the oil is employed to relieve an attack of hepatic colic various methods have been pursued. The oil has been given alone, in doses of about twelve ounces, taken in two equal parts, at an interval of fifteen or thirty minutes; it is sometimes used in combination with belladonna. Five ounces of oil may be administered with half an ounce of cognac, the white of two eggs, and some menthol; or four ounces of the oil may be given five or six hours after a slight repast, and on the next day an ounce and a half of castor oil. Villemin always employs the oil in four-ounce doses, preceded and followed by a mouthful of cognac or of brandy, which the patient may swallow or use as a gargle to overcome the disagreeable taste. Notwithstanding the usual repugnance or disgust that patients manifest for the remedy, vomiting rarely follows its administration. In some cases this even removes the sense of nausea that may previously have been present. The oil at once arrests the acute pains, and shortens the period marked by dull pains, weakness, malaise and jaundice, so common after attacks of hepatic colic.

PANCREATIC DIABETES.

Rendu (*La Semaine Médicale*, March 25, 1891) has described the varieties of glycosuria. Sometimes glycosuria is transient; the urine of certain individuals, overfatigued physically and especially mentally, from time to time contains traces of sugar. Such glycosuria disappears after some days of rest and seems to have no serious significance. It is the same with the glycosuria observed in some acute conditions, as in poisoning by the vapors of charcoal. In the cases indicated, the glycosuria is probaby a result of congestion of the bulb, and is not true diabetes.

Diabetes is probably always of nervous origin. Rendu is convinced that whenever glycosuria exists, the bulb is involved. In this category belong the cases of Claude Bernard, in which the diabetes was the functional expression of a lesion of the medulla or the fourth venticle. Leudet has reported cases of basilar meningitis with glycosuria; in some cases of diabetes Luys has post-mortem found marked congestion of the floor of the fourth ventricle; in still other instances, tumors have been found in the same region.

The most important and the most frequent form of diabetes is constitutional or diathetic, of which there are two varieties: adipose or gouty, and thin or pancreatic. The diabetes of the adipose or gouty is hereditary; it may continue for years without impairing the general health. It frequently alternates or coincides with other articular or gouty manifestations, or with such conditions as external hemorrhoids, eczema, migraine, or epistaxis; the patients are also often asthmatic. Some marked differences exist between these two types of diabetes. Gouty diabetes is insidious in onset; thirst may be absent; furuncles may appear, or an existing wound cicatrizes slowly; there may be itching of the genitalia; there are flashes of heat, or there is insomnia. The quantity of urine passed during the twenty-four hours does not usually exceed five liters (five quarts) with a maximum of from thirty to forty grams (from an ounce to an ounce and a quarter) of sugar per liter; emaciation does not usually result; finally, the quantity of sugar in the urine is readily controlled by treatment. Each year after a sojourn at Vichy or at Carlsbad, the sugar com-

pletely disappears from the urine, to reappear at the end of some months. Such patients, however, may live for many years without accident, save perhaps itching or an outbreak of furuncles. They must, however, be regarded as invalids, as in them surgical or medical disorders may assume a grave character and rapidly terminate fataly. In these cases there is nearly always a psychic cause for the condition—a strong emotion, or financial loss. The nervous system seems to play an important rôle. In some cases bulbar manifestations are seen, as, *e. g.*, albuminuria or polyuria, alternating or coinciding with the glycosuria.

The manifestations of pancreatic diabetes differ from the preceding. The patients are neither diathetic nor predisposed; suddenly, without apparent cause, without prodromes, grave diabetes is evident. Polydipsia associated with polyuria develops in the midst of apparent health, and a condition of pronounced debility is soon reached. In some patients intestinal disorders, paroxysmal diarrhea, ill-defined chronic enteritis, with rapid loss of strength, usher in the disease. The stools may contain free fat. The onset may be marked by cerebral disturbances, such as vertigo, somnolence or insomnia. Premature and absolute impotence not dependent upon general paralysis or locomotor ataxia should create a suspicion of diabetes. The patellar reflex may be abolished. In addition to the excessive thirst and appetite there is an unusual sense of fatigue, at first physical and soon intellectual; the patient becomes apathetic; in some cases moral depression may be the first indication of diabetes. While in the diabetes of the gouty or adipose the quantity of urine rarely exceeds three or four liters, in pancreatic diabetes it is often much greater. The degree of azoturia is proportional to the degree of glycosuria. Trophic disorders are prominent. Lesions of the retina are observed; the teeth and hair fall out; finally, a series of digestive disorders arise that lead to rapid emaciation. Tuberculosis frequently develops.

Lesions of the pancreas were long ago observed in cases of diabetes. In five cases of nine, Frerichs has noticed atrophy of the pancreas; while the lesions described have not in all cases been identical, they have all been associated with destruction of the organ. Atrophy is frequent; a sclerotic condition, either pericanalicular or perivascular, is often found. In some instances the volume of the pancreas was normal, but the glandular element was completely altered or had disappeared. In dogs, extirpation of the pancreas has been followed by diabetes with polyuria, glycosuria, and emaciation.

It seems, then, that a pathological relation exists between the condition of the pancreas and diabetes—a relation, however, the details of which are not yet understood. It is also probable that the polyuria and glycosuria are much more common as a result of disease of the pancreas than as a result of lesions of the fourth ventricle. The prognosis of pancreatic diabetes is much less favorable than that of diabetes in the adipose or gouty. In the pancreatic form therapeutics is entirely powerless; slight amelioration may be obtained from the administration of opium, antipyrine, arsenic, lithium, or the bromides; but the glycosuria cannot be made to disappear completely. In diabetes of the adipose, medication is speedily successful.

MEDICAL PROGRESS.

Concealed Rupture of the Perineum.—At the recent congress of the British Gynecological Society, THOMPSON (*Provincial Medical Journal*, July 1, 1891) described a condition in which the vagina is lacerated in its lower portion, the rent not involving the posterior commissure. Its occurrence is announced by a peculiar sensation imparted to the hand supporting the perineum during labor. Unless immediately repaired the injury may imperil the life of the mother, from the accumulation, decomposition and absorption of lochial discharge through the lymphatics of the perineal body, which communicate directly with the peritoneum.

Treatment of Diphtheria with the Galvano-cautery.—HAGEDORN (*Deutsche medicin. Wochenschr.*, No. 28, 1891) recommends the galvano-cautery in the treatment of diphtheria of the pharynx. The disease is conceived to be at first local and microbic, the constitutional involvement being secondary. A stirrup-shaped cautery is employed and is applied as soon as the diphtheritic membrane makes its appearance. Pain is overcome by preliminary cocainization. The reaction is slight. No harm is done if the membrane should prove not to be diphtheritic. The treatment has been pursued in twenty-four cases, with but one death.

Electrostatic Treatment of Strangury.—BENEDIKT (*Wiener medizin. Presse*, July 5, 1891) reports two instances of strangury, one in a case of tabes dorsalis, the other in a feeble-minded individual, and refers to others, in which, after other measures had failed, the application of static electricity, by means of the douche and the spark to the vertebral column and to the region of the bladder above the symphysis pubis, was followed by excellent results. The relief of the symptoms referable to the bladder is in turn followed by an ability to sleep.

Paralysis of the Vocal Bands and Icterus.—In conjunction with cases already reported by Gerhardt, and suspected of belonging in the category of Weil's disease, KAPPER (*Wiener medizin. Presse*, July 5, 1891) reports two analogous cases in which, following exposure to cold, there developed malaise, headache, fever, jaundice, aphonia, dysphagia and enlargement of the liver and spleen, which gradually subsided and were followed by recovery.

Sarcinæ in the Urine.—FINLAYSON (*British Medical Journal*, June, 27 1891) reports two cases in which sarcinæ were found in the urine. In one, in a man seventy-one years old, they were found at an interval of fifteen years. In neither was the health interfered with. In both a catheter had been used. In one, the urine contained neither albumin nor sugar; in the other, pus was present.

To Obviate the Entrance of Air into the Pleura in the Performance of Pneumotomy, ROUX (*Journ. des Soc. Scient.*, June, 1891), in a case in which he opened a tuberculous cavity in the lung, united the two layers of pleura by means of a continuous suture, thus closing the pleural sac against the entrance of air.

The Medical News.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment. When necessary to elucidate the text, illustrations will be provided without cost to the author.

Address the Editor: GEO. M. GOULD, M.D.,
1004 WALNUT STREET,
PHILADELPHIA.

Subscription Price, Including Postage in North America.

PER ANNUM, IN ADVANCE . . . . . $4 00.
SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, OCTOBER 17, 1891.

THE OPHTHALMIA OF INFANTS.

IT is no exaggeration to say that if the medical undergraduate were well instructed in one bit of knowledge it would be of more benefit to humanity than his whole course in obstetrics. And yet, generally speaking, it is true that during his entire three years of obstetric study he hears not a single word of this that should be a part of his teaching, this that could be learned in five minutes and that is of such enormous importance; but by a hundred lectures he is taught how to deliver women that, as a rule, without his help deliver themselves most excellently well. All of which long text must not be construed to mean any undervaluation of the importance and excellence of obstetric teaching as usually given in our colleges. It is to be construed solely as a desire to emphasize the fact of the duty neglected by the professor of instructing his classes in the prophylaxis and treatment of ophthalmia neonatorum. It may also stand as a protest against the outrageous negligence of medical colleges in not making ophthalmology an obligatory study, and in not making an examination in the treatment of the commonest ocular diseases a prerequisite of graduation.

For many years ophthalmic surgeons have been hammering away at this, writing, teaching, and begging their *confrères* to heed the lesson. It is a very simple lesson, a perfectly well understood pathology, an infallible prophylaxis, and, if caught in the easily recognized early stages of the disease, an almost infallible cure. In spite of this, what is the fact? There are perhaps 75,000 people in the civilized world blind from infancy solely because the lesson has not been heeded; every day there turn up at the oculist's office cases that make one's heart bleed —mothers heartbroken because the baby is blind— cases that need not have been; cases that, had the oculist seen them a day or two earlier, could still have been saved.

The public cost of keeping a blind person in our institutions is about $130.00 a year. If we suppose a like cost obtains elsewhere, we find the world's expense-item for inexcusable negligence in ophthalmia of the newborn to be something like ten millions of dollars per annum. For the United States alone this expense is probably nearly or quite two million dollars. But this is not all. Suppose the needlessly blind, instead of an expense, were, by the possession of visual power, productive members of the community, and suppose we estimate the average value of their labor at one dollar a working day. If, therefore, we add this loss of productive labor to the actual expense of the support of these blind, we have, for the civilized world, the stupendous sum of between thirty and forty millions, and for the United States alone some seven millions of dollars. Every State has, therefore, the most absolute of rights to demand that the medical colleges within her bounds shall fit their graduates to cope with this evil. Every taxpayer is interested. This, of course, is the very lowest, but a very palpable argument against such criminal negligence.

Last spring, and every spring, many students are graduated in the United States without a rag of knowledge or power of art to forefend all this. It is a strange illustration of how in medicine an œstrual fury for strange knowledge may seize upon men, bacteriomanias, hydrophobiaphobias, and all the rest, while the great, the feasible and the simple duty is scorned.

> "Our best things are nearest us—
> Lie close about our feet;
> It is the distant and the dim
> That we are fain to greet."

What is every obstetrician's duty as to the care of the newborn baby's eyes? Immediately after birth,

he should cleanse the lids and the face all about the eyes with a weak bichloride solution, and drop some of this, or of a one per cent. solution of nitrate of silver, on the globes. The baby's hands should also be aspecticized, and the nurse or mother instructed to cleanse her own hands, and not allow them, or cloths, handkerchiefs, etc., to come in contact with the infant's eyes. Despite these prophylactic measures, nurse, mother, and doctor must watch for the early signs of purulent conjunctivitis; any swelling or redness of the lids, or any purulent discharge from the eye, means that prophylaxis has failed, and that the entrenched enemy must be proceeded against with restless vigor. The eyes can still be saved.

Instead of this, what commonly happens? The baby's eyes or the dangers to them are never thought of, and when the lids of one eye begin to swell and a purulent discharge oozes from it, the mother is told by the nurse or someone else that the child has "only a little cold in its eye." The application of "breast-milk," or tea-grounds, or some such fol-de-rol is made, and the days go on while the eye is being ruined. If the doctor is called in he may vaguely suspect this to be something like a disease he dimly remembers to have heard of. If so, he prescribes a boric acid solution to be dropped into the eye. Even suppose the doctor realizes the danger (though this too rarely happens) and prescribes a true antiseptic, ten chances to one he will still make two fatal errors: he will order the antiseptic to be only dropped into the eye, and he will not isolate the diseased eye. He has never learned that there is no cure for purulent conjunctivitis unless the palpebral sulci are cleansed, and the germicide repeatedly brought into contact with every part of the palpebral and bulbar conjunctiva; and he has also not learned that, without isolation of the diseased eye and scrupulous precautions, pus from this eye is certain to get into the non-affected eye and ruin that also.

In such cases—constantly happening all about us—no conscientious physician would dare go on the witness-stand and testify that this is not unqualified malpractice, for which anyone guilty is liable for heavy damages. It would be a sad method of teaching a needed lesson, and one can only hope that for an individual's sake the lesson may not be so taught, though one must silently confess that should it arouse the whole profession to a realizing sense of its duty, the private and single tragedy would be for the common good.

A PAGE OF MEDICAL HISTORY.

THERE is a deal of good knowledge, good wit, and good literary work in the excellent article of DR. CONKLIN on "Molière and the Doctors" (*Transactions of the Ohio State Medical Society*, 1891). It is a pity that it should not have a wider circulation than a society report is likely to give it. This glimpse into the life of our professional brethren of only two hundred years ago is not only entertaining, but is of a double service; as the author acutely says:

"The medicine of the seventeenth century stands out prominently as one of the greatest landmarks in its history, and the story of its struggles and triumphs enables us to better understand the present and to more accurately forecast the future.

"We fortunately belong to a century which has illumined every department of human thought with learning and genius, and which has done so much for the upbuilding of scientific medicine. But we must not forget that each preceding age has wrought its full share in the evolution of medicine. It fell to the seventeenth century to break the chains of servitude and liberate medicine from the trammels of authority which had so long hindered the coming of modern science.

"To us it seems almost incredible that one of the most difficult lessons the race had to learn was to accept the testimony of the senses, and yet every page of history attests its truth. It is precisely here that we find the difference between ancient and modern medicine. The one concerned itself only with the proofs of authority; the other relies wholly upon the proofs of experiment and experience. Modern medicine aknowledges no intellectual restraint. She bids defiance to tradition, boldly questions authority, and sets precedent at naught. With the present means of inter-communication and interchange of ideas, which bring into elbow-touch co-workers in every corner of the globe, the day of long probation for alleged discoveries has gone forever. Illustrations crowd upon our attention. The Elixir of Brown-Séquard and Tuberculin of Koch, both too recent to need elaboration at our hands, strikingly illustrate the modern method of dealing with new problems. Every new hypothesis is at once submitted to fair but rigid laboratory and clinical tests, and by the result of these must it stand or fall. But opportunities bring with them responsibilities. A past, glorious in its achieve-

ments, warns us to avoid the errors of the epoch which we have been considering, lest another Molière should come gifted with the power to make us 'see oursel's as ithers see us,' and a future, splendid in its possibilities, lays upon us the obligation to so labor that the profession of medicine shall continue to advance with a broad front to greater victories."

Guy Patin, a Parisian physician of the seventeenth century, remarkable for wit, learning, and dogmatism, is thus neatly sketched:

"Patin was an active participator in the controversial disputes which raged around him. He combated the Arabians, denounced the surgeons and apothecaries, rejected the Harveian circulation and chemistry. He hated antimony because it came from the chemists and cinchona because it was introduced by the Jesuits. He believed implicitly in Hippocrates and Galen, in the old Faculty, and in Guy Patin. His creed contained but two articles: bleeding, and purging with senna. With a good lancet and a pound of senna he proposed to cure more patients than the Arabians with their polypharmacy. His love of bleeding was excessive, but in this he only reflected the orthodox practice of the day. He bled babes of three days and his mother-in-law of eighty years. He tells boastingly of a patient who recovered after seventy-two bleedings and forty purgings."

THE HOSPITAL AND DISPENSARY ABUSE.

The growing evil of the abuse of the benefits intended to be conferred by the charitable work of the hospitals and dispensaries of our large cities requires no special elaboration. The fact is too patent to escape the observation of even the least observant. It were urgently desirable that some appropriate remedy be devised for the correction of the evil. The abuse of a public charity must needs result in injury to both recipient and benefactor—and this injury is in turn transmitted from the individual to the community. It is gratifying to learn that the recognition of the wrong is eliciting expression in hospital reports, and especially gratifying that it should, in the following language, receive consideration in the second Report of the Superintendent (Dr. Henry M. Hurd) of such a model institution as the Johns Hopkins Hospital.

"It demoralizes any man to receive as a gift what he is able to pay for wholly or in part. Indiscriminate and hap-hazard charity begets habits of improvidence and a wastefulness, if not of actual vice among its recipients. No poor man, woman or child ought to suffer for good medical and surgical attention in this city from lack of ability to pay for it. On the other hand, no person should receive such attention as an absolute free gift who is able to pay any portion of the cost of it. I would urge that all applicants for relief at the Dispensary and Hospital be promptly and carefully scrutinized in the interests of both the public and the Hospital. In addition to the evil effect upon the community of indiscriminate charity, there is also danger of doing injustice to the profession of medicine which numbers among its members so many persons actively engaged in charitable work. Neither the Hospital nor Dispensary should interfere with the sources of support of these men by affording free medical or surgical treatment to those who are able to pay for it."

EXCISION OF PART OF RIGHT LOBE OF LIVER.

We learn that on October 9 Professor W. W. Keen, of Philadelphia, removed from a patient a considerable portion of the right lobe of the liver for the excision of a cystic tumor, the entire mass taken away being about two-thirds the size of a man's fist. The woman's temperature has remained normal, or nearly so, since the operation, rising only once to 100° F. There seems every reason to believe that the patient will recover.

SOCIETY PROCEEDINGS.

AMERICAN OPHTHALMOLOGICAL SOCIETY.

Twenty-seventh Annual Meeting, held at Washington, September 23, 1891.

Papers on the "Extraction of Cataract," were read by Dr. D. Webster, of New York, Dr. H. Knapp, of New York, and Dr. J. A. Lippincott, of Pittsburg. The first and second advocated so-called simple extraction; the latter performs preliminary iridectomy, and removes the cortical matter by syringing.

Dr. C. S. Bull, of New York, reported "A Case of Brain-tumor, with Autopsy." There were persistent inequality of the pupils, a history of previous syphilis, attacks seemingly of petit mal and lapses of memory; also paresis of the internal recti muscles and ptosis; moderate optic neuritis in the right eye, which afterward subsided under large doses of potassium iodide; and later hemianesthesia developed. There was no headache until a few hours before death. The autopsy revealed a large glio-sarcoma in the left frontal lobe, without a sign of meningitis.

Dr. P. A. Callan, of New York, reported two cases of "Orbital Traumatism, Followed by Immediate Monocular Blindness, and Subsequent Atrophy of the Optic Nerve Due to Fracture Involving the Optic Foramen."

In one case, the blow was received over the left eye, while the right became blind.

DR. MYLES STANDISH, of Boston, had seen two cases in which it was stated that blindness had developed immediately after injury, but there was no ophthalmoscopic evidence of injury; the pupils reacted to light. He was inclined to regard these patients as malingerers; but three or four months later, the evidences of optic-nerve atrophy appeared.

DR. S. B. ST. JOHN, of Hartford, had seen a case in which blindness resulted from a resection of the infra-orbital nerve, attended with more than the usual amount of hemorrhage.

DR. S. D. RISLEY, of Philadelphia, had seen four cases of monolateral atrophy of the optic nerve, three of them following blows on some portion of the orbital ridge, and one after a blow on the top of the head.

DR. R. A. REEVE, of Toronto, reported a case of "Traumatic Pulsating Exophthalmos Treated by Ligation of the Common Carotid." The patient had received a kick on the side of the head and in a few days was conscious of a shrill sound, that later became a purring bruit, and pulsating exophthalmos developed. Compression of the carotid controlled the pulsation and bruit so long as it was continued, but intermittent compression kept up for hours at a time, over three months, failed to effect any permanent improvement. Five hours after the ligation of the carotid, the bruit returned. although it was readily controlled by compression of the other carotid. Ligation of the second carotid was advised.

DR. GEORGE C. HARLAN, of Philadelphia, had seen a case in which cure had been effected in six months by intermittent compression. The patient devised a pad and applied the treatment himself.

DR. E. GRUENING, of New York, found divergent squint quite amenable to the ordinary operative treatment, but the operation must be performed with a freer division of the tissues than for convergent squint. After the tenotomy he passes a ligature from one eye to the other, and leaves them fixed in a decidedly convergent position.

DR. S. M. BURNETT, of Washington, read a paper, entitled "Contributions to the Study of Heterophoria," which will appear in a later number of THE MEDICAL NEWS. He had found heterophoria less frequently than ametropia a cause of eye-strain. While, theoretically, prisms should be sufficient to afford relief, there were practical difficulties connected with their use, and it is a serious matter to have to constantly wear glasses of any kind if it be possible to dispense with them. This it is often possible to do by graduated tenotomy, which he believed could be adapted to the needs of the case. He reported a series of headaches of the severest type almost entirely relieved by such operations.

DR. GEORGE C. HARLAN, of Philadelphia, described a modification of Dieffenbach's operation for the restoration of the lower lid, designed to prevent dragging on the transplanted flap, or on the external canthus by cicatricial contraction, by replacing the flap used in reconstructing the lid by a second, sliding flap taken from the temple, where the cicatrization of a considerable raw surface would cause no injurious traction.

DR. S. THEOBALD, of Baltimore, reported two cases of successful skin-grafting for extensive loss of the substance of the eyelids. Thiersch's method was employed and the grafts were taken from the inner surface of the forearm and placed on the raw surface from which granulations had been removed.

DR. GEORGE E. DE SCHWEINITZ, read a paper, entitled "Neuroma of the Right Upper Eyelid and Adjacent Temporal Region," in which he described a case of neuroma of the upper eyelid and adjacent temporal region that had occurred in his service in the Philadelphia Hospital, and that had been observed both by his colleague, Dr. George M. Gould, and by himself. The growth was congenital, affected the upper eyelid of the right side and the right temporal region, the patient at the time of examination and operation being a lad of twenty years of age. Dr. de Schweinitz had performed three operations upon this case; the first a dissection of the tumorous mass from the eyelid, the second a plastic operation to relieve the resulting entropion, and the third, Panas's operation for ptosis, the final result of the surgical interference having been a reasonably good effect. Although clinically the case had presented the appearance of a fibro-fatty tumor, or perhaps of a circumscribed congenital elephantiasis of this region, a careful microscopic examination revealed that in addition to an overgrowth of the connective tissue of the part, as well as of the connective tissue of the walls of the vessels, sebaceous glands and hair-follicles, there were large strands of soft connective tissue, in the center of which were compressed and atrophied nerve-fibers. In all probability the growth had developed from the fibrous sheath of small cutaneous nerves, and had later involved the connective tissue of the structures just named. The research was illustrated by microscopic slides and a series of micro-photographs that had been prepared from these slides by Dr. William M. Gray, of the Army Medical Museum.

DR. F. M. WILSON, of Bridgeport, read a paper on "The Use of Vaselin in Gonorrheal Conjunctivitis," in which he advocated the employment of vaselin as an important adjunct in treatment. The unguent furnishes a protecting coating to the cornea, aids in keeping clean the conjunctival sac, and greatly diminishes the pain and risk of perforation of the cornea. He reported the results of its use in forty-seven cases, on which his conclusions were based. To be efficient, the vaselin must be applied freely between the lids, and the manipulation of the eye continued until the unguent has become liquid and made its way to every part of the conjunctival sac.

DR. H. KNAPP, of New York, demonstrated and recommended a roller-forceps for the mechanical treatment of trachoma by extrusion of the exudate from the conjunctival tissue. He had used the forceps in fifty-eight cases, and found that it caused less laceration of the tissues than other methods of accomplishing the same purpose. Cases of follicular disease are permanently cured by one thorough expression of the diseased tissues, while cases of mixed character may in addition require a few weeks' treatment with astringents. The mechanical treatment of trachoma is certainly a great advance over the method by the repeated use of caustics and astringents alone.

DR. E. E. HOLT, of Portland, Me., reported six cases of extraction of foreign bodies from the vitreous. In

several the wound of entrance was enlarged and the bit of steel searched for and extracted with the electro-magnet. In one, in which the foreign body was not a bit of steel, the wound was extended and the body was extracted with the forceps. In all but one case the result was most satisfactory; in that case two weeks had elapsed without efficient treatment.

Dr. S. B. St. John, of Hartford, reported three cases of extraction of foreign bodies from the eyeball, in one of which a bit of wire from a whip-lash remained, transfixing the cornea, iris and lens for a month, without great reaction in the eye. In another, a foreign body imbedded in the iris was removed by drawing out a portion of the iris, releasing the body and returning the iris to the eye substantially uninjured. In the third case, a bit of steel discovered at the back of the eye with the ophthalmoscope was left to become encapsulated.

Dr. L. H. Taylor, of Wilkesbarre, reported a case of brain-tumor with a high grade of choked disk, in which there were no convulsions, except a falling-down at the beginning of the symptoms, from which time on the patient was confined to the house. The optic nerves later became atrophied and there was hemianesthesia. At the autopsy a large glioma was found springing from the corpora quadrigemina and the floor of the fourth ventricle, pushing up the posterior lobe of the cerebrum and causing an erosion of the overlying portion of the skull.

Dr. Albert G. Heyl, of Philadelphia, read a paper on "The Caliber of the Retinal Vessels in Injuries of the Convexity of the Brain." This paper was a contribution to what Dr. Heyl calls diametroscopy of the retinal vessels, or the study, by inspection, of their diameter. The clinical material upon which the observations were made consists of twelve cases of injury to the vault of the cranium, drawn for the most part from the wards of the Episcopal Hospital for the purposes of study. These cases are divided into two groups: 1. Those that presented the phenomenon of delirium, or the initial stage of it. In this group, the retinal veins, while but slightly altered in diameter, were rounded in contour, and had a circular cross-section. The arteries showed a decided tendency to contraction. One was a case, typical of the group—a case of pure brain-contusion, ending fatally. At first a slight enlargement of the arteries was noted, followed to the close by steady contraction. This contraction was a slow process. An additional case was cited in which head-injury was followed by atrophy of the optic nerve, and the retinal vessels presented appearances analogous to those already described. Two cases were also reported, in which intracranial hemorrhage—at least, in one case—occurred at the time of injury, from a wound of the arteria meningea media, requiring ligature; in these the diameter of the vessels varied somewhat from that described. 2. In this group a psychical phenomenon that Dr. Heyl calls *sopor alternans*, was presented—*i. e.*, the condition in which a patient, after a severe head-injury, becomes alternately conscious and unconscious. In the most typical of the three cases in this group, in the *sleeping* stage the pupil is contracted, in the *waking* stage dilated; corresponding changes were noticed in the retinal vessels. In the *sleeping* stage the veins were about normal in diameter, the artery three-quarters of the normal diameter; in the *waking* stage, both arteries and veins were contracted to one-half the normal diameter.

Dr. T. G. Sutphen reported three cases of amaurosis; one after suppression of the menses, another after parturition, and a third with complete blindness in one eye without ophthalmoscopic changes. The first and second progressed to atrophy; in the third, partial recovery ensued.

Dr. G. E. de Schweinitz, of Philadelphia, next read a paper entitled "Additional Experiments to Determine the Lesion in Quinine-blindness." He briefly reviewed the results of his previous experiments to determine the lesion in quinine-blindness, in which he showed that quinine given to dogs in quantities varying from one grain to four grains to the pound produces blindness in from three to fourteen hours, the earliest appearance of the amaurosis after the injection being three hours. The ophthalmoscopic picture in these animals was in all particulars similar to that which has been noted in human beings suffering from quinine-amaurosis.

A second series of experiments was detailed in the present paper, by which it was shown that the same results can be produced with all the various salts of quinine, and that the prolongation of quinine-blindness produces a true atrophy, sometimes associated with the production of thrombosis in the central vessels. The sections upon which these facts were based were made by Dr. William M. Gray from a dog that had been for two months kept completely blind. The microscope showed cupping of the optic-nerve entrance, complete atrophy of the optic nerve, chiasm and optic tracts, an organized thrombus in the central vessels, and some degeneration of the lenticular ganglion. A very remarkable fact is the selection of the optic nerve for the influence of quinine, as careful sections of the ciliary and other cranial nerves showed absolutely normal structure. Both of these sets of experiments seem to prove that the action of poisonous doses of quinine is originally due to a constriction of the peripheral vessels; that later on, distinct changes, either in the blood itself or in the bloodvessels, are developed, and that consequent thrombosis may occur, followed by a complete atrophy and fatty degeneration of a large portion of the visual tract.

Dr. Charles A. Oliver, of Philadelphia, read a paper entitled "A Clinical Study of the Ocular Symptoms Found in the So-called Mongolian Type of Idiocy." He found that the irregularity, inequality and malposition of the bony orbits and their contents, which more than anything else characterize the Mongolian type of idiocy, are instances of general osseous and ligamentous malformations characteristic of the disorder. The eyeball itself presents the results of a low grade of chronic neuro-retinitis and choroiditis. The intra-ocular termination of the optic nerve and adjacent retina share in the soft gelatinous edema recognized in the external portions of the organ. The mucous membranes of the eye and its appendages are liable to the chronic inflammations that occur in other mucous membranes. As part of the imperfect development and consequent disease of the entire vascular system, the walls of the retinal vessels appear thin, peculiarly tinted, and there are hemorrhages into the retina.

Dr. Edward Jackson, of Philadelphia, called attention to an unavoidable distortion of lines seen through

cylindrical lenses, unless such lines run parallel or perpendicular to the axis of the lens. The distortion varies with the strength of the lens and its distance from the eye. With lenses of unequal strength or with axes not parallel the distortion necessitates a readjustment of balance for the oblique muscles, and this is capable of causing eye-strain, which is lessened by placing the lenses as close as possible to the eye.

DR. L. H. TAYLOR, of Wilkesbarre, reported a case of insanity following the instillation of atropine into the eyes of a young woman who had been under severe mental strain, partly from nursing an insane mother. She had used the drops two days without unusual symptoms, and then had paroxysms of causeless weeping and developed melancholia.

DR. S. D. RISLEY, of Philadelphia, in a note on hyoscyamine, reaffirmed his high estimate of its value as a mydriatic, but stated that it was a drug extremely liable to essential alteration in the process of manufacture, and that many preparations of inferior quality were on the market. To get its good effects one must use a crystalline hyoscyamine prepared by one of the best makers.

DR. SAMUEL THEOBALD, of Baltimore, called attention to subnormal accommodative power as a cause of asthenopia. It is to be remedied by the wearing of convex lenses for near work, with decentering outward if necessary.

The following officers were chosen for the next year:

President.—Dr. Hasket Denby, of Boston.

Vice-President.—Dr. Geo. C. Harlan, of Philadelphia.

Secretary and Treasurer.—Dr. S. B. St. John, of Hartford.

Corresponding Secretary.—Dr. J. S. Prout, of Brooklyn.

AMERICAN OTOLOGICAL SOCIETY.

Twenty-fourth Annual Meeting, held at Washington, September 22, 1891.

DR. H. KNAPP, of New York, read a paper entitled, "Operations for Mastoid Disease," in which he reported two cases. In the first there was otorrhea, intense headache, nausea, giddiness and some stupor. In the fourth week the mastoid was opened to the depth of fully half an inch, but no pus was found. The patient was at first relieved, but his symptoms afterward returned, and he died comatose in the eighth week. The autopsy disclosed diffuse purulent meningitis and a small abscess in the jugular fossa, separated from the wound of operation by a thin layer of healthy bone. Had the operation gone a little deeper it might have saved the patient's life. In the second case the prominent symptom was severe pain, radiating from the mastoid, and bulging of the upper part of the drum membrane. Treatment failed to afford relief, and the mastoid became tender and doughy. An extensive opening in the mastoid disclosed intense congestion of the bone and the membrane lining the air-cells, and a few granulations, which were removed. The patient was relieved by the operation and got quite well. Operation is justified in congestive mastoiditis, which otherwise is apt to persist for years, and lead to sclerosis.

DR. C. J. BLAKE, of Boston, reported twenty-three recent cases of operation, with removal of all diseased bone by curetting with a sharp spoon after perforation with a drill. In several cases the cure was complete in two weeks or less; but in some, in which the operation had been long delayed, the cure was slower, and the permanent damage great. In one case death resulted after the inefficient treatment of making an incision only through the soft tissues; and in another, in which the operation was delayed, metastatic irido-choroiditis caused the loss of an eye; there was also involvement of the hip.

DR. E. GRUENING, of New York, found tenderness over the affected part the constant and significant indication for opening the mastoid. He removes all the cortex of the bone and finds no after-treatment required.

DR. F. M. WILSON, of Bridgeport, maintained that no single symptom can be regarded as conclusive. He had seen two cases of pyemia from mastoid disease, one of them ending in death by pulmonary abscess.

DR. B. A. RANDALL, of Philadelphia, reported a case of suppuration about the ear, with epileptiform seizures of growing frequency. Exploratory trephining was performed behind the meatus. Slow healing went on to the fourteenth day, when there were pain and swelling below the mastoid, followed by severe headache, meningitis, and death on the twenty-third day. The autopsy disclosed denudation of the antrum and attic, with erosion of the ossicles, and sub-arachnoid purulent effusion with no trace of direct communication from the temporal bone. A series of specimens from fatal cases were exhibited, showing various channels of communication of the inflammatory process with the intra-cranial structures.

DR. J. M. RAY, of Louisville, reported a case of acute suppuration of the middle ear, causing meningitis and death, in which the autopsy revealed no involvement of the temporal bone; the septic infection seemed to have taken place through the general circulation.

DR. CHARLES H. BURNETT, of Philadelphia, read a paper on "Excision of the Membrana Tympani and Necrotic Malleus for Chronic Purulent Otitis Media," reporting four cases in which, after the failure of all other rational treatment, he had excised the tympanic membrane and the malleus. In the first case suppuration of twenty-five years' standing was checked, hearing remaining unaltered. In the second, the discharge was lessened, but not checked; hearing improved from ten inches to ten feet. In the third—a case of chronic suppuration, with frequent cholesteatomatous collections and pain—the discharge was checked and the hearing improved from zero to two feet. In the fourth, one of thirty years' standing, the discharge ceased and the hearing improved from six inches to eight feet.

DR. SAMUEL THEOBALD, of Baltimore, read a paper on "Healing of Old Perforations in the Drum Membrane." He reported some partially successful efforts to promote healing of old perforations of the tympanic membrane by the wearing of artificial drum-membranes of absorbent cotton moistened with vaselin. These must be carefully placed and renewed every week or so. He had also added balsam of Peru for its stimulating effect.

The following officers were chosen for the next year:

President.—Dr. Gorham Bacon, of New York.

Vice-President.—Dr. Huntington Richards, of New York.

Secretary and Treasurer.—Dr. J. J. B. Vermyne, of New Bedford, Mass.

AMERICAN PHYSIOLOGICAL SOCIETY.

Second Special Meeting, held at Washington, D. C., September 22, 23 and 24, 1891.

First Day—September 22d.

Dr. H. N. Martin, of Baltimore, read an interesting paper on "The Effects of Bleeding and Starvation upon the Proteids of the Blood." In his experiments he used cats. They were bled twice. At the first bleeding from 50 c.c. to 80 c.c. of blood were withdrawn, and after an interval of twenty-four hours the animals were bled to death.

The blood was subjected to an analysis which showed in every case a marked decrease in the amount of proteids contained in the blood obtained in the second bleeding, while the fibrinogen was greatly increased in quantity. From his experiments Dr. Martin wished to show that hemorrhage caused a great diminution in the proteids, while the fibrinogen was greatly increased between the first and second bleedings, as a result of the manufacture of red blood-corpuscles from the hematoblasts which threw out their nuclei in this process, and that it was from these extruded nuclei that the great increase of fibrinogen was derived.

Dr. S. J. Meltzer, of New York, read an elaborate paper on the "Respiratory Changes of the Intra-thoracic Pressure, Measured in the Mediastinum Posterior," in which he endeavored to show that the method of measuring the intra-thoracic pressure through the esophagus could not be relied upon, owing to the irregularity of the thickness of the walls of the esophagus. The method of Dr. Meltzer consisted in making an incision in the crico-thyroid muscle, and gently passing a catheter down into the mediastinum posterior. By connecting this catheter, by means of a rubber tube, with his registering apparatus, he was able to get a correct record of the intra-thoracic pressure. It was found that the pressure above the fourth rib was considerably less than that below that level.

Second Day—September 23d.

Dr. Wm. Noyes read a paper on "Experimental Studies on the Knee-jerk in Terminal Dementia. (*a*) During the cycles of depression and exaltation. (*b*) During sleep."

In his experiments Dr. Noyes clearly demonstrated that except during a period in which the subject was in a state of profound mental depression, the knee-jerk was as distinct as in the normal individual; during conditions of depression, however, it was greatly diminished; while with the disappearance of these conditions the knee-jerk again returned to its normal condition. It was demonstrated that during sleep the knee-jerk could be elicited without awakening the hemispheres—that is, the leg would respond to a blow upon the ligamentum patellæ that was not sufficient to interfere even with the snoring of the subject. Any unusual noise in the room, such as walking across the floor, slamming a door, or rapping upon a table at the time the blow was struck, would greatly increase the force of the knee-jerk.

When the subject was in a condition of semi-sleep, *i. e.*, not snoring, the curves on the tracing-paper caused by the knee-jerks were irregular, but, as soon as the subject was awakened and spoken to, they again became regular. This, it was thought, was caused by the fact that, when the subject was awakened, more blood was sent to the spinal cord, as a result of which the reflex again became normal.

Dr. J. W. Warren, of Boston, followed with a paper on "The Knee-jerk Studied Simultaneously in Both Legs."

In his experiments he arranged two hammers, by means of springs, so that every blow was struck with the same force, and so that either one or both legs could be struck simultaneously or successively at a short interval. When, after a subject had been struck a number of double blows, a single blow was suddenly given to one leg alone, both legs would respond to the stimulus.

Dr. Warren also brought out the fact that when a series of single blows were given to one leg alone and then a double blow was suddenly struck, he would fail in a great many instances to get a double jerk. This failure was more marked in the right leg than in the left, the left responding in 16 per cent. of the cases and the right in only 9 per cent. This difference he attributes to the fact that the left leg is the one usually used in making a test, and in a series of experiments this difference is greatly diminished.

When a series of single blows were struck on one leg and then a single blow was struck on the other leg, a response was often wanting. This failure was also more frequent on the right than on the left. During sleep, he often failed to get any response to a blow, unless a noise was made at the time of striking the blow. In some cases, however, a second blow would bring out a response without the assistance of a noise.

Third Day—September 24th.

Dr. W. P. Lombard, of Worcester, Mass., read an interesting paper on "Some of the Influences that Determine the Strength of Voluntary Muscular Contractions," as determined by a simple and effective apparatus that was exhibited. Dr. Lombard's experiments were all conducted upon himself; the results obtained were eminently satisfactory. He demonstrated that loss of power was due to fatigue of the central nervous system and not to fatigue of the muscles themselves. When the muscle was no longer able to lift a weight, it was stimulated by electricity and promptly responded by a strong contraction, showing that the muscle was not fatigued. When the weight was detached from the muscle, the will-power could induce a contraction; so that the fatigue was somewhere between the muscle and the brain. Dr. Lombard also showed the influence exerted by weather, food, exercise, alcohol and tobacco upon the amount of work performed. Food, exercise and alcohol increased the amount of work performed. When the barometer was rising, power increased; with a falling barometer there was a de crease of power. High temperature diminished power.

Humidity and high temperature diminished power. With the humidity not excessive, and the temperature not very high, there was but little effect upon power. Whenever he smoked a cigar, his power diminished. Exercise increased his power. The greatest increase of power he derived from a small quantity of whiskey and water; and as the quantity of whiskey taken was small, there was no after-depression. His power also changed with the diurnal changes of the barometer, so that his minimum power was at 4 P.M.

DR. C. F. HODGE, of Worcester, Mass., followed with a valuable paper on the "Diurnal Changes in Nerve-cells as the Result of the Normal Activity and Rest of the Animal." His experiments showed a decided shrinkage in the nuclei of the nerve-cells examined in the evening, when compared with those examined in the morning.

DR. H. P. BOWDITCH, of Boston, read a paper on "The Fatigue of Nerve-fibers, studied by Means of the 'Action' Current."

DR. V. C. VAUGHAN, of Ann Arbor, read an abstract of a paper in which he detailed the discovery of a new bacterial product from typhoid germs. This product is so poisonous that when ten milligrams were injected into a guinea-pig, it caused death in half an hour.

The session was closed by the reading of a paper on "The Size of the Cranial Nerves in Man," by DR. H. H. DONALDSON, of Worcester, Mass.

ASSOCIATION OF AMERICAN ANATOMISTS.

Fourth Annual Meeting, held at Washington, September 23, 1891.

APPROPRIATE resolutions on the death of Professor Joseph Leidy, President of the Association, were offered by DR. D. S. LAMB and passed by a standing vote.

DR. WM. P. CARR, of Washington, read a paper entitled "The Systematic Use of the Eye in Teaching Anatomy," in which he maintained that the training of the hand by dissection of the subject and attention in the lecture-hall to didactic statements are not sufficient for all purposes of education, but that the teacher, with chalk in hand, drawing outlines upon the blackboard or demonstrating from models on the lecture-table, is doing more important work. The ability to prepare papier-maché models is a desirable accomplishment. The speaker exhibited one model, made by himself, representing the human cerebrum, with the special object of giving correct impressions of the fornix and the descending horn of the lateral ventricle. Dr. Carr claimed that with a little practice anyone could make models at comparatively slight expense. The full text of the paper will appear in a later number of THE MEDICAL NEWS.

DR. HARRISON ALLEN, of Philadelphia, read an elaborate paper on "The Teaching of Anatomy to Advanced Students." He claimed that those who, after completing their medical studies, still desired to advance in the direction of anatomical research, had little or nothing offered them in our medical schools; a movement should be initiated to establish courses of instruction for such men. In his judgment, this plan would embrace a scheme of physiological anatomy that might be said to represent the plan designed over a hundred years ago by John Hunter. Dr. Allen approved of the establishment of a Hunterian museum, and, if practicable, of a Hunterian laboratory, in connection with the University scheme. Dr. Allen's paper will appear in full in a later issue of THE MEDICAL NEWS.

DR. ROBERT REYBURN reinforced Dr. Allen's claim as to the physiological basis of teaching anatomy. The three papers elicited much discussion, which, on the whole, was favorable to the tenets claimed.

DR. WM. BROWNING, of Brooklyn, read a paper on the "Arrangement of The Supra-cerebral Veins in Man, as Bearing on Hill's Theory of Developmental Rotation of the Brain," in which he endeavored to show that the disposition for the transverse cerebellar veins to remain at right angles to the main axial vein was evident throughout life. Owing to the curvature of the cerebrum forward during development, the veins in this portion of the encephalon depart from the embryonic scheme indicated and the vessels become displaced obliquely downward and backward.

PROFESSOR D. J. CUNNINGHAM, of Dublin, by invitation of the Chair, made an interesting statement respecting the development of the fissure of Rolando and the adjacent fissures, as well as those of the island of Reil. He showed the harmonies existing between the two sets of fissures. All the fissures named appear to be composed of three distinct simple involutions that become united at a late phase of development.

DR. C. HEITZMANN, of New York, read a paper on "The Structure of Basis-substance and Cement-substance." He had already shown that the basis-substance of all the varieties of connective tissue is structural, but freely supplied with living matter, in the same way as is protoplasm. The changes that take place in the process of inflammation, the reappearance of protoplasm after a liquefaction of the more solid substances, filling the meshes of the reticulum of living matter, likewise furnish proof of the vitality of basis-substance. Heitzmann was also the first who succeeded in demonstrating the reticulum in living protoplasm. The cement-substance between the individual epithelial and endothelial cells is traversed by delicate processes that have been shown to penetrate deeply into the protoplasm of epithelial cells. These processes are also constituted of vital matter and actively participate in the process of proliferation in inflammation as well as in the formation of tumors. Thus the continuity of living matter is established in all the tissues throughout the animal and vegetable organism, and the main point of the cellular theory, that cells are individuals, is proved to be a fallacy.

DR. W. M. GRAY, of the United States Army Medical Museum, exhibited a number of serial fetal sections mounted in large frames. He also showed a number of enlarged photographs of the same sections.

DR. HARRISON ALLEN, of Philadelphia, made some remarks on the teeth of cheiroptera. He claimed that some of these teeth were tactile in function, since from their small size and the absence of fixed positions they could have no use in attrition or prehension. In some genera, the cingula on the premolars were entire, features unknown in any other of the mammalia. The reduction in size of the last molar was secured by a novel method, the tooth not becoming rounded or nodular, as is the

rule, but the plan of the fluted and complex form of the anterior molars being retained, even as a rudiment. The action of the tongue as a mechanical factor in forcing the teeth apart was dwelt upon, and comparisons were drawn between the appearances seen in the condition known as macroglossia as met with in man, and the arrangement of the teeth in animals having long, prehensile tongues.

Dr. E. A. Balloch, of Washington, D. C., read a paper on "The Relative Frequency of the Psoas Parvus Muscle in the Colored Race." It was shown that the psoas parvus is almost invariably present in the negro on both sides and is well developed, while in the white race it is infrequently so.

Dr. Frank Baker, of Washington, presented specimens of platycnemic tibiæ, as well as exceptional forms of femora and fibulæ that had been claimed as having value in identification of race. Dr. Baker claimed for such peculiarities less importance than had been accredited them by writers.

Dr. D. S. Lamb, of the Army Medical Museum, Washington, D. C., read a paper upon "The Supra-condyloid Process in the Human Subject." An examination of over 620 humeri from whites, blacks and Indians, of both sexes and of all ages, showed the presence of this process but once. This rarity was in striking contrast to the frequency with which the anomaly has been found by European observers, as Gruber and Struthers. The analogy of the process to the supra-condyloid foramen in the lower animals was discussed. Both the foramen in them and the process in man were to convey the brachial vessels and median nerve and protect them from pressure in lateral movements. The process is a muscular tubercle for the attachment of an anomalous slip of the pronator radii teres muscle.

The paper concluded with a contrast between such animals as the cat, which have this foramen, and dogs, which do not have it, but do have the olecranon perforation (not present in cats), and discussed the significance of these facts in relation to the natural movements of those animals. As to the process in the human subject, it was apparently a reversion.

Mr. F. A. Lucas, of Washington, exhibited museum specimens designed to demonstrate homologies of bones in the skeleton of man and the animals related to him.

The paper of Ida H. Hyde, of Chicago, entitled "Notes on the Hearts of Certain Mammals," was read by title. From a study of the hearts of many animals, certain facts were observed and conclusions reached warranting further investigation. According to some authorities, the presence of the tuberculum Loweri and Eustachian valve in the cat have as yet not been determined. Nevertheless, Miss Hyde found in the heart of every animal examined what she considers the homologue of the tuberculum Loweri of the human heart.

She found the Eustachian valve only in man and in the monkey, and a remnant of it in the cat. It extends caudally over the orifice of the coronary sinus, and protects it, differing in these respects from that of man. It is this valve that in the cat has been mistaken by anatomists for the Thebesian valve.

The statements concerning the Thebesian and Vieussens valves are perplexing. Some writers state that the Thebesian valve covers the orifice of the coronary vein, whereas this orifice is guarded by the Vieussens valve—so named in honor of its discoverer. According to other writers, the coronary valve guards the orifice of the coronary sinus; but the valve protecting this orifice was first described by Thebesius, and in his honor called Thebesian valve. It is a crescentic valve at the cephalic edge of the orifice.

Miss Hyde rejected the generalization that the Thebesian valve is present in every instance in which the coronary sinus receives blood from the heart alone, as in man and the cat, but is absent in those animals that have a left precava, or left azygos, as in sheep and the rabbit, since she had found the Thebesian valve in the rabbit, in which, according to this generalization, it ought not to be, while it was absent in the panther, the cat, and the dog, in which, according to the statement, it ought to be present.

Since a valve protecting the termination of the middle cardiac vein existed in every heart examined, and as it is not named, Miss Hyde suggested that it be called the coronary valve.

Some anatomists hold that the coronary sinus is the lower dilated part of the left azygos or left precava when it exists, and that the great coronary vein opens into this trunk. Others, again, claim that the coronary sinus is the dilated part of the coronary vein. Miss Hyde believes that the coronary sinus is the persistent primitive ductus Cuvieri, and that the great coronary vein empties into it, as well as the left azygos or left precava when it exists, the blood passing through it to the right auricle.

Since the oblique vein of Marshall does not send branches into the substance of the heart, it is not, as the older anatomists thought, a branch of the great coronary vein. Although said to be unprovided with a valve, Miss Hyde found one over its orifice in the heart of the Cebus monkey. Inasmuch as the embryo heart shows the oblique vein of Marshall to be the termination of the primitive left precava, she cannot agree with those who hold that it is the termination of the left azygos.

The following resolutions were adopted:

Whereas, The subject of comparative anatomy of race is an important one, and special advantages for the observation and collection of material therefor are afforded among the negro race in North America; be it

Resolved, That this Association recommend that a circular be prepared by the Executive Committee for distribution among the anatomists of North America, inviting coöperation;

Resolved, That the Executive Committee is authorized to incur a cost in printing and distributing these circulars to an amount not exceeding $25.

Fifteen new members were elected.

The following embrace the officers of the Association for the ensuing two years:

President.—Harrison Allen, of Philadelphia.

Vice-Presidents.—Charles Heitzman, of New York; T. N. Gill, of Washington, D. C.

Secretary and Treasurer.—D. S. Lamb, of Washington, D. C.

Delegate to Congress.—F. J. Shepherd, of Montreal. *Alternate:* R. W. Shufeldt, of Washington.

Executive Committee.—Burt G. Wilder, of Ithaca; T. Dwight, of Boston, and E. C. Spitzka, of New York.

THE AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION.

First Annual Meeting, held at Philadelphia, September 24, 25, and 26, 1891.

FIRST DAY—SEPTEMBER 24TH.

THE President, DR. G. BETTON MASSEY, delivered an address entitled "A Plea for the Associated Cultivation of Special Expertness in Medicine," which will be found elsewhere in the current number of THE MEDICAL NEWS.

DR. A. D. ROCKWELL, of New York, read a paper entitled "Electro-therapeutics in America," which is to appear in a subsequent number of THE MEDICAL NEWS.

DR. BLACKWOOD, of Philadelphia, stated that he had operated on thirteen cases, each of which had been diagnosticated by at least one eminent gynecologist. He had used the faradic current of a strength as great as could be borne, and preferred faradism to galvanism because of the action of the former on the muscular fibre. He maintains that the faradic current does destroy the integument. For the last ten years he had obtained the best results from central treatment, which he considers the best means to overcome obscure nervous affections. Nevertheless, he often depended on localized treatment as well.

DR. AUGUSTIN H. GOELET, of New York, read a paper on "The Action and the Application of the Faradic Current in Gynecology," in which he maintained that imperfectly constructed apparatus is the cause of the indifferent results that have been obtained by various observers. The construction of secondary coils has heretofore been looked upon with such indifference by physicians who use them, that the manufacturers, with no guide for their construction, have suited their own convenience, regardless of the physiological effects to be produced. In consequence, these coils in the ordinary apparatus will be found constructed of wire from No. 15 to No. 26, and from sixty feet to two hundred yards in length. Experience has shown that the faradic batteries of ordinary construction are totally inadequate for gynecological work, and satisfactory results cannot be expected from their use. The uncertainty of the statements of manufacturers regarding the length of the wire composing secondary coils has led Dr. Goelet to advise those who desire to be accurate to measure the resistance of their coils and calculate the length for themselves. He considers the Engelmann battery, with three different secondary coils, to be the only reliable apparatus manufactured in this country, suitable for gynecological work. In it the secondary coarse-wire coil is made of No. 16 wire, about 75 yards long; the intermediate is of No. 22 wire, 225 yards long; and the fine-wire coil is of No. 32 wire, about 660 yards long.

Though these coils are to be regarded as a great improvement on others, they do not wholly meet the requirements of gynecological work, since in very sensitive conditions the current from the finest coil cannot be borne. It has, therefore, been suggested that one spool should contain 1500 yards of No. 36 wire, which, if tapped at 1000 yards, would give two additional coils, one of 1000 and one of 500 yards in length; then another coil of No. 32 wire, 800 yards long, tapped at 500 yards, would give a coil of that length, one of 300 and another of 200 yards; then there is another coil of No. 22 wire, 250 yards long, to correspond with Engelmann's intermediate. There should also be a coarse-wire coil of No. 16 wire, about 100 yards long. By this arrangement practically eight different coils are secured, and a corresponding variation of the current, with but four spools; so that it would be possible to treat very sensitive conditions that could not be approached with the other coils.

Evidence was adduced and experiments cited showing conclusively that there is a marked difference in the effect of the current as it is derived from coarse-wire and fine-wire secondary coils, and in accordance with different lengths of wire of the same size. The current from the coarse-wire coil is one of volume or greater ampèrage, as distinguished from that of the fine-wire coil, which is a current of tension or greater electromotive force. The former is useful for muscle-stimulation, the latter for nerve-sedation. The failure to obtain satisfactory results with the faradic current was attributed to the imperfect and variable construction of apparatus by different manufacturers. The use of a rheostat or controller in the secondary circuit does not sufficiently influence the physical conditions of the current to make one coil suitable for all purposes.

The vibrator or current-breaker upon the ordinary faradic apparatus produces interruptions entirely too coarse, while the movement is uneven and irregular. To produce sedation with the fine-wire coil a maximum rapidity of interruption should be obtained; there should be not 50 or 80 interruptions, as is usually the case with the ordinary apparatus, but from 100 to 200, per second. Coarse interruptions are more stimulating and irritating, while fine interruptions are more sedative. It is important to use coarser vibrations for the coarse-wire coil, and finer vibrations for the fine-wire coil. The current from the coarse-wire coil is used for muscular stimulation, and that from the fine-wire coil for sedation. In applying the current for muscle-stimulation it is desired to produce alternate contraction and relaxation in imitation of the normal physiological action; the interruptions must be slow, so as to allow the muscles time to respond in a normal manner—that is, sufficient time must be allowed between the interruptions to allow the molecular changes to take place. In effecting sedation it is desired to paralyze the sensory nerves and to exhaust and relax the muscles, thus relieving the painful contractions; the interuptions must therefore be fine. When the interruptions are rapid the muscles are unable to respond to every vibration, and constant contraction or a tetanoid condition is produced, which eventually exhausts the contractile power of the muscles, so that a condition of relaxation is produced if the application is continued long enough. This constant and intense stimulation of the sensory nerves likewise results in a temporary loss of their power to respond, and a condition of anesthesia is brought about, which is more or less prolonged, according to the duration and frequency of the applications. To secure sedation the application should be maintained for from ten to twenty minutes; the strength of the cur-

rent must be increased gradually, without jerk or shock, and it should be withdrawn in the same manner. The duration of the application of the current from the coarse-wire coil should be limited to five minutes.

As a result of the influence of the current upon the vasomotor nerves and the capillary circulation, blood-stasis is relieved and the absorption of effete products is hastened.

Dr. Goelet maintained that the faradic current displays polarity; observation has shown that there is a distinct difference in the physiological action of the two poles. This is explained by the fact that, on account of the high resistance of the human body, only the break-current has a perceptible action, the make-current being cut down to such an extent by self-induction as to make its action upon human tissues inappreciable. Hence, when used upon human structures, the faradic current may be said to flow in one direction; it is not an alternating, but an interrupted current.

The best effect of the secondary current is obtained only when the secondary coil completely covers the primary coil, that is, when the whole of the secondary coil is receiving the full amount of induction. In order to secure this from the beginning of the application and at the same time to make it bearable to the patient, a rheostat or regulator, composed of fine German-silver wire of a length sufficient to afford adequate resistance, is placed in the battery circuit. By this means the operator has perfect control of the current and graduates it in accordance with the requirements of the case. The increase or decrease of the secondary current is regulated by increasing or diminishing the strength of the current in the battery circuit by means of this regulator, which interposes a variable resistance. The method of operation consists in applying the electrodes with the secondary coil removed from the primary coil; then allowing just sufficient current to flow through the regulator in the battery circuit to operate the vibrator smoothly, but feebly; the secondary coil is then slowly moved until the primary coil is completely covered. The strength of the current is still further increased by allowing more current to flow through the rheostat or regulator until the desired intensity is reached. Applied in this way, the best effect of the secondary current is secured from the beginning of the application, and the most sensitive conditions, that could not possibly be treated in the ordinary manner, may be brought under its influence.

Acute inflammatory processes are also amenable to treatment with the faradic current, under suitable conditions of high tension, as when it is derived from a coil of very fine wire of great length, if a maximum rapidity of interruptions with perfect smoothness is secured—the effect being obtained by restoring the equilibrium of the circulation.

Dr. Bigelow, of Philadelphia, stated that clinically there is a very marked, decided, and important difference between primary and secondary currents. In all cases of ovarian troubles the current from the secondary coil is the only one that will be tolerated. He had seen cases of ovaritis, characterized by persistent and aggravated pain, yield at once to applications of the secondary current; similar cases were aggravated to a degree unbearable by the primary current. In some recent observations he had seen ovaritis yield more rapidly to the static current, which is more like the faradic. The sensation produced by the secondary current is pleasant; the action of the current as a sedative is marked.

The secondary current is much less a muscular stimulant than the primary current. In cases of pain and of fibroid tumors the faradic current is to be preferred.

Dr. Hayes, of Chicago, stated that clinical experience had demonstrated that the faradic current is sedative in its properties, and the question now presents itself, How can the sedative properties necessary in ordinary practice be developed? He had not been able to recognize any physiological difference between the two poles of the faradic battery; he was satisfied that pain can be relieved with either pole; whether one has a more sedative property than the other he does not know. The fine wire is capable of affording relief, but is also capable of doing great mischief. In subacute conditions inflammation may be lighted up by a weak current of a few minutes' duration. Dr. Hayes related the case of a young woman with pain and tenderness in both inguinal regions, in whom the temperature at no time was more than 99.5°. After three or four days' treatment with the ordinary hot douche and potassium bromide, an application of the faradic coil was made. The pain was somewhat relieved, but in the course of a few days it was evident that a hematoma had developed in the posterior cul-de-sac.

Dr. Hutchinson, of Providence, expressed himself as emphatically in favor of the secondary current. He uses a large coil of some miles of wire, made so that it is tapped at various points so that it can be increased or diminished in force at will.

In a good many years of practical work he has not found any difference in the faradic effects of one pole or the other. The varying number of feet or yards of wire has an effect on the circulating current.

Dr. Walling, of Philadelphia, suggested that perhaps some of the effects noted are due to the rapidity of the vibrations rather than to the coil used. In using the secondary coil he is accustomed to throw the whole coil in and take the current from the rheostat. In this way he obtains better results than in attempting to take a part of the coil. He distinguishes the polarity of the current. In many cases the positive pole appears to be more sedative in its influence than the negative, yet both will relieve pain.

Dr. Morton, of New York, made the point that there is a good deal of misunderstanding concerning the faradic current. The faradic current may be interrupted or alternating. The primary is alternating. A standard induction battery is desirable—a standard coil—a standard length of wire; then comparative observations could be made. Different results may be accounted for by differences in the character and length of the secondary coils. Polar effects may depend upon peculiarities of construction. As the number of coils is increased the voltage and force are also increased. As Dr. Gordon, as a result of his careful measurements, says: the induction-current, the secondary current of the break, measures thirteen times more in intensity than the same current of make. So the make of the primary exerts its entire influence in charging the coil of the secondary. If the current of the break is thirteen times

greater than the current of the make, then one of the impulses is thirteen times stronger than the other. One end of the line will do thirteen times more electrolytic work than the other. Dr. Morton, however, would not admit that the current-intensity of the make is not sufficient to penetrate the human tissues. If the electromotive force of the make, secondary, is not sufficient to penetrate the human tissues, the therapeutist is not treating disease by the alternating current at all, but by the interrupted current.

DR. WAITE expressed the view that to get at the proper coil it is necessary first to make a proper primary and then a secondary current. The number of vibrations has much to do with the sedative effect of the primary current.

DR. MASSEY, of Philadelphia, thought that the problem was one of a technical character and that much can be done when a meter is devised to measure the faradic current, for the whole question at the present time is very much in the same condition as that of the galvanic current was prior to the invention of the milliampère-meter. Dr. Massey has obtained marked contractile effects in certain myomas, in strong primary currents, and good contractile effects in the abdominal walls and intestinal walls by using large poles, one on the back and the other on the abdomen.

The variation between the primary and secondary currents is extremely remarkable. Patients who feel no contraction from the secondary current cannot stand one-quarter of a like strength from the primary. Why? Partly at least because it is in one direction, but more because there is more ampèrage, which is greater when the external resistance is small and the wire coarse.

DR. GOELET added that there is no doubt but that the faradic current as it is employed to-day is merely an interrupted and not an alternating current.

The more rapid the interruptions the more sedative the effect.

If the two currents are applied to resistances like the skin by small electros, one over the hand and another far away at some indifferent point, the current from the fine wire will produce a better contraction than the coarse, because there is more current. Still, if the resistance in the skin is cut down and made little or nothing, as when both electrodes are taken in the hand, or as in the vagina, then, of course, the electro-motive force is not so necessary. The same muscular contractions are not obtained as with the coarse-wire coil.

DR. BIGELOW said the secondary coil is too valuable to be lost sight of; it is because it is so little understood that it is not used more. He had found the apparatus that he was using satisfactory, but discarded it on account of the pain it caused. He expressed the hope that a standard instrument would be devised.

DR. L. A. W. ALLEMAN, of Brooklyn, N. Y., read a paper upon "The Treatment of Corneal Opacities by Galvanism." He had endeavored to test thoroughly the efficiency of galvanism in one class of cases, *i. e.*, opacities. After the subsidence of the corneal inflammation which has given rise to the opacity, the eye usually remains for some time in an irritable condition; it flushes easily, and shows evidence of a high vascularity, an increase of nutritive activity in the neighborhood of the scar. Sometimes vessels are seen running on to the cloudy area; and when this is the case the prognosis is relatively more favorable. For some little time the reparative process may go on with much activity, especially in young subjects; the cloud diminishes in density and extent, but more or less quickly it returns to a condition of normal nutrition; the scar-tissue becomes more resistant and the clearing up proceeds more and more slowly, till it finally ceases. In this stage much can often be accomplished by treatment. Such agents as an ointment of the yellow oxide of mercury, calomel dusted into the eye, massage, and the like, prolong the reparative process. But finally a stage is arrived at where the process is perfectly quiet, and no further absorption of the opaque tissue can be induced. It occurred to Dr. Alleman that in this stage the galvanic current was indicated. He believed the reason why it had not been more successful was that when used through the closed lids, the necessarily feeble current employed on the eye could not produce at the site of the lesion sufficient stimulation to bring about the desired effect, and to meet this indication he had an electrode made, consisting of a silver bar, 12 mm. in length, insulated, except at the ends, by a hard rubber shell; the exposed surface at the lower extremity is slightly concave, 7 mm. in diameter.

A battery of Leclanché cells, a Fleming milliampère-meter, and a rheostat complete the outfit. He uses for an electrode upon the cheek a carbon disc with a short metal handle which fits into a hard-rubber shell. The disc is covered with moist absorbent cotton, held in place by the shell, and is renewed each time the instrument is used.

The cathode is applied to the cornea. Before placing the electrode upon the cornea the patient is directed to touch it to the tip of his tongue, as this gives about the same resistance as through the cornea, and the rheostat is then adjusted until the strength of current desired is obtained. This seems a necessary precaution, as the cocainized cornea might be seriously damaged without any sensation of pain giving warning. The eye being previously well cocainized, the operator stands behind the patient, whose head is thrown back, and, holding the lids well apart with the thumb and first finger of the left hand, the electrode is brought in gentle contact with the cornea.

As a rule, the applications are of three minutes' duration. A strength of ½ milliampère, applied for from one to two minutes, is begun with; if the current is well borne the strength of current is gradually increased to from 1 to 1½ milliampères and the length of the sitting to three minutes.

The results of this method of treatment are satisfactory in the extreme. The duration of the opacity seems to make little difference in the prognosis. The visual results obtained will depend largely upon the position of the cloud. When concentric with the pupil, little improvement is seen till late in the treatment; but when the pupil is covered by the lap of the opacity, the visual improvement is very marked at the outset; this is due to the fact that the scar always clears up from the periphery toward the more dense center. When the scar vascularizes easily the prognosis is most favorable, however old or dense the opacity may be.

In the small, very white scars sometimes seen in adherent leucomata, it takes a very long time to influence

the center of the opacity, and the patient, who is elated by the marked visual improvement obtained by the first few treatments, becomes discouraged with the much slower progress of the central opacity; but in such cases as have persevered for some time there has been a slow but steady improvement, even in the dense white scars.

NEWS ITEMS.

The New York State Medical Association will hold its eighth annual meeting October 28, 29 and 30, 1891, at the Mott Memorial Hall, New York City.

The President, Dr. Stephen Smith, will deliver an address on The Art of Teaching Medicine.

Papers will be read as follows:

The Use of Chloroform in Labor. By Dr. Elbert T. Rulison.

Forced Respiration—Continued Observations. By Dr. George E. Fell.

Preventive Medicine. By Dr. Henry C. Van Zandt.

The Theories of Rheumatism. By Dr. John Shrady.

A Discussion on Acute Diffuse Peritonitis will be opened by Dr. Alfred L. Carroll, and will be participated in by many prominent physicians and surgeons.

Dr. Nicholas Senn will deliver the Address on Surgery.

Other papers will be read as follows:

Dislocation and Fracture of the Vertebræ. By Dr. Charles W. Brown.

Two cases of Forward and Outward Dislocation of the Astragalus, with Mode of Reduction and Result. By Dr. Douglas Ayres.

Larvæ of Dipteræ in the Human Intestine. By Dr. Homer O. Jewett.

Report of an Unusual Case: Was the Diagnosis Correct? By Dr. Simeon Tucker Clark.

Heredity and Environment. By Dr. Judson B. Andrews.

Traumatism, Shock; Moral Causes and Causes Operative at Physiological Epochs. By Dr. H. M. Hurd.

Arrest of Development and Diseases of Infancy. By Dr. E. N. Brush.

Bodily Diseases and Senility. By Dr. P. M. Wise.

Syphilis and Intemperance. By Dr. G. Alder Blumer.

Causes of Insanity Peculiar to Women. By Dr. W. D. Granger.

Tumors of the Orbit and Neighboring Cavities. By Dr. Charles Stedman Bull.

Biblical Medicine. By the Rev. Dr. William C. Bitting.

Orton Prize Essay.

Address on Gynecology. By Dr. A. Palmer Dudley.

Mental Therapeutics. By Dr. Henry D. Didama.

Subjects of Interest, Medical and Surgical. By Dr. John Cronyn.

An Ethical Imbroglio. By Dr. George E. Fell.

The Relation of Nervous Disorders to Indigestion in Women. By Dr. T. J. McGillicuddy.

Carcinoma Mammæ: What May We Expect After Operative Treatment? By Dr. John A. Wyeth.

Disease of the Knee-joint in the Convalescent Stage. By Dr. T. M. L. Chrystie.

Retro-bulbar Optic Neuritis. By Dr. Alvin A. Hubbell.

Typhoid Fever in Children. By Dr. William D Garlock.

Congenital Imperforate Rectum. By Dr. E. D. Ferguson.

The Tenth International Medical Congress at Berlin as I Saw It. By Dr. George Douglas.

Puerperal Eclampsia at the Seventh Month; Induced Labor; Recovery. By Dr. George E. Fell.

Biology and Medicine. By Dr. Hubbard W. Mitchell.

Lateral Curvature of the Spine Associated with Hernia. By Dr. S. E. Milliken.

Dr. James C. Wilson has been elected to the chair of the Practice of Medicine and Clinical Medicine in the Jefferson Medical College, made vacant by the resignation of the distinguished Dr. J. M. Da Costa.

Books and Pamphlets Received.

A Short Manual of Analytical Chemistry, Qualitative and Quantitative, Inorganic and Organic. Arranged on the Principle of the Course of Instruction given at the South London School of Pharmacy. By John Muter, M.D., Ph.D., F.R.S.E., F.C.S. First American from the Fourth English Edition, edited by Claude C. Hamilton, M.D., Ph.G. Philadelphia: Published by P. Blakiston, Son & Co., 1891.

Quiz Compends. Physiology. By Dr. A. P. Brubaker, A.M., M.D. Sixth Edition, Revised and Improved, with new Illustrations and a Table of Physiological Constants. Philadelphia: P. Blakiston, Son & Co., 1891.

Scientific Medicine in Its Relation to Homeopathy. By Professor Theodor Bakody, M.D., of the Buda-Pesth University Translated from the German by Rudolph Bauer, M.D. Philadelphia: Boericke & Tafel, 1891.

Addresses, Papers, and Discussions in the Section of Surgery and Anatomy at the Forty-Second Annual Meeting of the American Medical Association, at Washington, D. C., May 5–8, 1891. Chicago: Printed at the Office of the Association, 1891.

The Relation of Concussion of the Brain and Spinal Cord to Inflammatory and Other Morbid Conditions of these Organs. By B. A. Watson, A.M., M.D. Reprint, 1891.

Deaths from Chloroform and Ether since the Hyderabad Commission; with Conclusions. By Laurence Turnbull, M.D., Ph.G. Reprint, 1891.

Spasmodic Wry-neck and Other Spasmodic Movements of the Head, Face, and Neck. By Noble Smith, F.R.C.S. Ed. London: Smith, Elder & Co., 15 Waterloo Place, 1891.

Conditions Following Parturition Requiring Abdominal Section. By E. E. Montgomery, M.D. Philadelphia: Reprint, 1891.

The Sloane Maternity Hospital. Report on the First Series of One Thousand Successive Confinements from January 1, 1888, to October 1, 1890. By James W. McLane, M.D. Reprint, 1891.

Handbook of Materia Medica, Pharmacy, and Therapeutics, including the Physiological Action of Drugs, the Special Therapeutics of Disease, Official and Practical Pharmacy, and Minute Directions for Prescription-Writing. By Samuel O. L. Potter, A.M., M.D. (Jefferson), M.R.C.P. (Lond.). Third Edition, Revised. Philadelphia: P. Blakiston, Son & Co.

Diseases of the Nasal Organs and Naso-pharynx. By Whitfield Ward, A.M., M.D. New York and London: G. P. Putnam's Sons, 1891.

A Handbook of Obstetrical Nursing, for Nurses, Students, and

Mothers. By Anna M. Fullerton, M.D. Second Edition, Revised. Philadelphia: P. Blakiston, Son & Co., 1891.

Charaka-Samhita Translated into English. Published by Abinash Chandra Kaviratna. Calcutta: Printed by D. Dass & Co., Corinthian Press, New China Bazaar, 1890. (Pamphlet.)

The Malthusian Theory of Population. By W. H. Washburn, M.D. Reprint, 1891.

Some Experiments on Acetonuria in Diabetes Mellitus, and on the Physiological Action of Acetone in the Animal Organism. By G. Metzler, M.D. Reprint, 1891.

Transactions of the South Carolina Medical Association; Forty-first Annual Meeting, held in Anderson, S. C., June 9 and 10, 1891. Charleston, S. C.: Walker, Evans and Cogswell Co., Printers, 1891.

Manual of Childbed Nursing. By Charles Jewett, A.M., M.D. New York: E. R. Pelton, 1891.

Surgical Treatment of Intussusception. By N. Senn, M.D., Ph.D. Toronto: Reprint, 1891. Printed by The J. E. Bryant Co. (Limited).

The Scientific Rationale of Modern Wound Treatment. By Henry O. Marcy, A.M., M.D., LL.D. Chicago: Reprint, 1891.

Transactions of the Medical Society of the State of West Virginia; Twenty-fourth Annual Session, held at Fairmont, June 10, 11, and 12, 1891. West Virginia Printing Co., Printers.

Saunders' Question-Compends, No. 1. Essentials of Physiology arranged in the form of Questions and Answers. Prepared especially for Students of Medicine. By H. A. Hare, B.Sc., M.D. Third Edition, thoroughly Revised, and Enlarged by the addition of a series of handsome Plate Illustrations taken from the celebrated "Icones Nervorum Capititis" of Arnold. Philadelphia: W. B. Saunders, 1891.

"Pulmonary Consumption a Nervous Disease" (by Thomas J. Mays, M.D.) Considered as Such from a Practical, a Clinical, and a Therapeutic Standpoint. By Thomas J. Mays. Detroit: George S. Davis, 1891.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM OCTOBER 6 TO OCTOBER 12, 1891.

BANISTER, JOHN M., *Assistant Surgeon.*—Granted leave of absence for four months.

SUTER, WILLIAM N., *Assistant Surgeon.*—Granted leave of absence for one month, to take effect on or about October 15, 1891.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING OCTOBER 10, 1891.

DICKSON, S. H., *Surgeon.*—Ordered to Marine Barracks, Washington, D. C.

MAGRUDER, A. F., *Surgeon.*—Detached from Marine Barracks, Washington, D. C.

FEREBEE, N. McP., *Surgeon.*—Ordered to the U. S. S. "Atlanta."

DRENNAN, M. C., *Surgeon.*—Detached from tho U. S. S. "Atlanta."

TRYON, J. R., *Surgeon.*—Ordered to the U. S. S. "Chicago."

WALTON, J. C., *Medical Inspector.*—Detached from the U. S. S. "Chicago," and granted six months' leave.

KEENEY, J. F., *Passed Assistant Surgeon.*—Detached from the U. S. S. "Minnesota," and ordered to the Naval Hospital, New York.

CRANDALL, R. P., *Passed Assistant Surgeon.*—Detached from the Naval Hospital, New York, and ordered to the Naval Laboratory.

BOYD, ROBERT, *Assistant Surgeon.*—Detached from the Marine Rendezvous, Boston, and ordered to the U. S. S. "Chicago."

ALFRED, A. R., *Assistant Surgeon.*—Detached from the U. S. S. "Fern," and ordered to the U. S. S. "Kearsarge."

GATES, M. F., *Assistant Surgeon.*—Detached from the U. S. S. "Kearsarge," and ordered to the U. S. S. "Fern."

AMES, HOWARD E., *Surgeon*—Ordered as Delegate to the Public Health Association, Kansas City, Mo., October 20, 1891.

NORTH, JAMES H., *Assistant Surgeon.*—Resignation accepted September 8, 1891.

TO CONTRIBUTORS AND CORRESPONDENTS OF THE MEDICAL NEWS.

THE MEDICAL NEWS begs its contributors and correspondents to observe the following:

1. Contributors of original articles, lectures, clinical memoranda or hospital notes, will, upon publication of their communications, be liberally paid, either

a. In cash, or

b. In reprints (250).

It should be distinctly stated, either at the head of the communication or in the accompanying letter, which method is preferred.

2. Copies or abstracts of papers must not have been or must not in the future be furnished any other journal, or published elsewhere, unless the fact have been clearly stated prior to the acceptance by us of the article. *Without an understanding to the contrary, it is held to be a matter of simple honesty that communications sent* THE NEWS *are for its exclusive use.*

3. The rejection of a manuscript does not necessarily imply any adverse editorial judgment as to its literary or scientific value. There are many other reasons that often prevent the acceptance of a manuscript. It may, for example, be rejected because another and similar article upon the same subject has already been accepted and awaits publication; because it could not be published for so long a time that it would become unseasonable; because it would more appropriately appear in some other journal, etc., etc. We cannot undertake to explain the especial reason for not accepting a paper.

4. The probability of the acceptance of an article, as well as the likelihood that it will be extensively read, is greatly enhanced by its brevity. Useless introductions and more useless perorations are always well omitted. Expression should be condensed; not so much as to exclude or to render obscure important things, but sufficiently to economize the time of the busy and tired practitioner and save mental friction in clearly comprehending the article. The results of good thinking, good observation, or good work, can be given in few words—and, with certain rare exceptions, it is results that medical men want.

5. THE NEWS especially desires brief, crisp clinical memoranda and short, concise articles on living subjects—articles epitomizing observations and facts occurring almost daily in the practice of every practitioner. A vast deal of material highly valuable to medical science and to humanity is constantly lost because busy men feel that they have not the time or ability to write elaborate papers. This is wrong. Everyone has some peculiar experience, sees exceptional aspects and phases of disease, has peculiar abilities or methods of practice, comes repeatedly upon a highly anomalous, suggestive, instructive, or interesting case. If such cases were properly placed on record, medicine would be greatly advanced. THE NEWS desires to become the medium of such publication and record.

6. Communications should be prepared in compliance with the following suggestions:

a. Paper larger than 8 × 10 inches should never be used.

b. The paper should be good, white writing paper, not news or tissue-paper.

c. If possible, a manuscript should be type-written.

d. Only one side of the paper should be written upon.

e. A blank margin, at least one inch wide, should be left at the left-hand side of the sheet.

f. Communications should be written in black, non-copying ink.

g. Writing, and especially all proper names, should be distinct and plain.

h. A sheet on which many corrections, interlineations, etc., have been made, should be rewritten.

i. If possible, manuscript should never be folded or rolled.

7. Communications in reference to subscriptions, advertisements, or other business should be addressed to the publishers, MESSRS. LEA BROTHERS & CO., 706 and 708 Sansom Street, Philadelphia. Communications pertaining to the reading columns should be addressed to the Editor:

GEORGE M. GOULD, M.D.,
1004 WALNUT STREET, PHILADELPHIA.

ORIGINAL ARTICLES.

OBSERVATIONS ON TORTICOLLIS, WITH PARTICULAR REFERENCE TO THE SIGNIFICANCE OF THE SO-CALLED HEMATOMA OF THE STERNO-MASTOID MUSCLE.[1]

BY ROYAL WHITMAN, M.D., M.R.C.S.,
ASSISTANT SURGEON TO OUT-PATIENTS, HOSPITAL FOR RUPTURED AND CRIPPLED, NEW YORK.

ASSUMING that the treatment of any affection must to a great extent depend upon our apprehension of the causes that produce it, I shall call your attention more particularly to etiology, the conclusions being influenced by clinical investigation rather than by recorded theories.

That the bearing of these conclusions on the question indicated by the title of this paper may be clearly understood, I quote from several of the more prominent writers on the subject. F. Busch,[2] for example, says: "Congenital wry-neck is caused, as Stromeyer was the first to show and as is now acknowledged, almost without exception by injury to the sterno-cleido-mastoid muscle at birth, and by subsequent shortening at the place of injury by scar-contraction. The deformity occurs almost exclusively in children delivered by forceps, or more frequently in breech or foot presentations."

In the *Deutsche Chirurgie*[3] the subject is treated by Fisher as follows: "It is certain that tearing of muscle at birth, as Stromeyer has shown, is a frequent cause of torticollis. A tumor appears at the seat of the injury a few weeks after birth, which slowly disappears, leaving shortening by scar-contraction."

Volkmann and Vollert[4] have resected and examined portions of muscle in cases of supposed congenital torticollis. In some no change was apparent; in others the muscular substance had entirely disappeared to be replaced by fibrous tissue; while in the remainder the fibrous degeneration was diffuse, as shown by bands in the muscle substance. These changes they regard as the result of myositis caused by injury at birth. While these observations are of value as showing changes that may occur in persistent wry-neck, they can have but little bearing on the question under consideration, as no evidence is presented of original injury or of subsequent induration, and because similar changes are found in cases of acquired torticollis of long duration, as reported by Robert, Marchessaux, Bouvier, and Witzel.[1]

It is evident that the term injury is not used by these and other writers in a general sense, but applies to partial rupture of the sterno-mastoid muscle—caused, it would appear, by torsion[2] of the neck during delivery of the head, followed by effusion of blood,[3] and later by an encapsulating inflammation[4] at the seat of the injury, as shown by a hard, painless tumor in the substance of the muscle. This induration slowly disappears, to be replaced by fibrous tissue, which, contracting, creates permament torticollis—in other words, a purely mechanical shortening, as distinct from the nerve irritation and spasm that we usually associate with wry-neck. As to the first part of this proposition—that injury of muscle may occur during labor, and that it is followed by induration at the seat of the rupture—there can be no doubt but that such rupture is followed by scar-contraction; that it is the usual cause of congenital torticollis is extremely improbable. A partial subcutaneous rupture of a normal muscle would seem to present every requisite for quick and perfect repair. Scar-contraction never follows similar injuries in later life, nor do we find in other situations anything analogous after injury at birth. If, then, we are to accept this theory, it would seem that the supporting evidence should be very direct and conclusive, such as the recorded observations of a number of cases—from the original injury, with its succeeding induration and scar-contraction, to the persistent torticollis which is supposed to result. Such evidence, however, is not contained in the literature of the subject, although the theory—originating fifty years ago with Stromeyer[5] and Dieffenbach—has been endorsed by nearly[6] all subsequent writers, gathering weight, it would appear, by reiteration, rather than from actual investigation. It should be stated that this theory of the origin of congenital torticollis has been vigorously com-

bated by Peterson[1] and flatly denied by Weiss,[2] as follows: "Ruptures of the sterno-mastoid muscles are frequent enough during labor, but they are never followed by torticollis, and it is impossible to accept the theory advanced by Stromeyer and Dieffenbach."

It is apparent that we may obtain reliable evidence on this question from two sources: cases of induration followed to their termination, and cases of supposed congenital torticollis traced back to injury and subsequent induration, if such existed.

In the records of the Hospital for Ruptured and Crippled were found eighteen cases of so-called hematoma; nine could be traced, and of these two were excluded for mistaken diagnosis—the first because the after-history seemed to point to an inflamed gland as the cause of the induration; the second because the mother is positive that no tumor was present at any time. In both instances the torticollis, that was the prominent symptom, quickly and permanently disappeared. The history and results in the remaining cases are as follows:

CASE I.—A male infant brought to the hospital on August 26, 1889, at the age of two months. Fifth child, delivered by version, arm broken in the act. Three preceding children had died during labor. Tumor, size of a hazel-nut, in the middle of the right sterno-mastoid, hard, not sensitive; noticed by the mother at six weeks; no torticollis; no symptoms. The infant died eighteen days after.

CASE II.—Male, brought on August 16, 1889, at the age of three weeks. First child; delivered by forceps after tedious labor. Tumor, size of a large almond, in the left sterno-mastoid muscle; not sensitive to pressure; noticed at ten days. No torticollis; no symptoms. The swelling disappeared in three months. Child examined at nineteen months; no trace.

CASE III.—Male, seen August 28, 1890, at the age of five weeks. First child; forceps delivery after difficult labor. Tumor, size of a small pigeon's egg, in the middle of the left sterno-mastoid; noticed at three weeks. No torticollis or other symptoms. The swelling disappeared in three months. Examined at the age of nine months; no trace remaining.

CASE IV.—Female, brought September 16, 1890, at eleven weeks. First child; breech presentation. Delivered by a midwife with some difficulty. Tumor in the middle of the right sterno-mastoid, size of a hazel-nut; noticed at eight weeks. No torticollis. The induration disappeared in four months. Examined at eight months; no trace.

CASE V.—Male, seen May 2, 1891, at two months. Breech presentation, spontaneous and easy labor. Tumor size of a hazel-nut in the upper third of the right sterno-mastoid; noticed at three weeks. A gurgling respiration was apparent when the child nursed the left breast. There was no torticollis, though slight resistance on extreme tension of the affected side.

Examined at the age of six months. No torticollis or restriction of motion. No symptoms. Tumor slightly smaller, otherwise unchanged.

CASE VI.—Male, brought July 31, 1891, at seven weeks. Third child, transverse with arm presentation, delivered by version and forceps. Complete paralysis of the right brachial plexus; right inguinal hernia. A spindle-shaped enlargement of the middle third of the right sterno-mastoid, one-half inch in diameter, hard, not sensitive. No torticollis. No symptoms. Last seen September 5, 1891. No apparent change in the tumor.

CASE VII.—Male, seen August 5, 1891, at five weeks. First child; breech presentation, difficult labor. Tumor size of a pigeon's egg, at sternal insertion of the right sterno-mastoid; hard, not sensitive to pressure. No torticollis or other symptoms. Not again examined.

With these I now include six cases recently reported by Quisling,[1] in which the indications correspond to my own, although the actual results were not in all instances ascertained. Thus, of the thirteen cases, nine were originally breech presentations or delivered by version, two were extracted by forceps, and in two there is no history of interference with delivery. Of these cases, examined with especial reference to the subject of torticollis, in none was it present at the first examination, other than the slight limitation that might be supposed to follow a tumor of this size and character in the muscle substance, and in none of the cases traced did it follow. It should be noted, also, that there are on record other instances of complete disappearance of these tumors without succeeding deformity, as for example, cases reported by Brooks,[2] by Smith,[3] by Jacobi,[4] and many others.

Having considered the question from the standpoint of original injury, traced to recovery in all all the cases cited, we may now invert the method and examine the evidence presented by cases of congenital torticollis pointing to injury at birth as the exciting cause.

At best, such evidence is unsatisfactory, because we must depend upon the mother's statement as to the time when the affection appeared. Infants do not support the head for several weeks after birth, and unless the deformity is extreme it is not noticed until that time. If, then, an infant is brought for examination at the age of six months with a history of torticollis first noticed at four weeks, we may consider it of intra-uterine origin, or that it was acquired during the first month of life, or caused by injury at birth. If we favor the first conclusion,

[4] Archives of Pediatrics, March, 1888.

then congenital torticollis must be divided into two classes.

First, cases of slight deformity, with no pain and but little spasm, except on extreme tension of the contracted parts, the contraction not being limited to the sterno-mastoid, but all the lateral tissues being involved. The resistance is not marked and the deformity can be easily overcome in a short time by stretching and manipulation. These cases are very similar to the mild condition of talipes calcaneus or of incomplete extension of arms or legs, equally amenble to treatment, whose origin would seem to be a constrained position *in utero*, leading to general shortening of tissues on the one aspect, with weakening and lengthening on the opposing surface.

The second class is composed of cases where the deformity is more marked. It cannot be overcome by simple means, but persists and increases. The sterno-mastoid may alone be affected, or the posterior group of muscles, with compensatory curvature of the spine and displacement of the scapula, as in one case now under observation. Here, we may infer, there is an actual arrest of development or muscle-degeneration, arising, it may be, from causes more complex than appear in the preceding cases.[1]

In regard to rupture of muscle as a possible cause, it may be said that the tumor of true hematoma is so prominent when the child turns the head, that it could hardly escape the mother's notice, and her statement in this regard may be accepted as final. During the past six months I have had the opportunity of examining four cases of congenital torticollis in young infants, three of the first class and one of the second. Although there was a history of transverse presentation in one of the milder cases, in none of these, nor in those seen in later life, was there history or evidence of hematoma or of difficulty in delivery or probability of injury at birth.

In considering the significance of hematoma, so called, several sources of error should be indicated, as leading to the present confusion on this subject:

1. A muscle shortened *in utero* may be ruptured at birth, thus presenting a deformity where the induration is a coincidence and not a cause.[2] Such a case was reported by Bruns[3] at the last Congress of German Surgeons.

2. An inflamed gland, adherent to the muscle, with torticollis from nerve irritation, may be mistaken for hematoma, as in the case mentioned.

3. Similar enlargements may in certain instances be of other origin than injury—such as fibrous, sarcomatous,[4] or syphilitic tumors, arising, it may be, *in utero*. Cases reported by Graser, Taylor,[1] Hadra,[2] and Holmes[3] would seem to support this view.

It is possible, too, that injury in a tuberculous or syphilitic child might give rise to a myositis sufficiently exaggerated to cause permanent arrest of development and actual shortening.

In regard to injury in general, this is undoubtedly an occasional cause of acquired torticollis. It might operate at birth as in later life, and hematoma might be a coincidence, or we may fancy that fibers of the spinal accessary nerve might be involved in the induration following muscle rupture, with irritative spasm as a result. These, however, are simply conjectures, and are entirely distinct from the question of scar-contraction that we are considering. It may be objected that the negative evidence presented is of true value, compared with positive observations to the contrary, but it must be remembered that we are considering the usual and not the exceptional causes of wry-neck, and that neither Stromeyer nor any of the succeeding writers who have endorsed this theory have presented a single undoubted case in its support.[4] Of the hypothesis, then, that explains the origin of congenital torticollis by muscle rupture, myositis, scar-contraction, and permanent shortening, we may conclude that it is simply an assertion unsupported by evidence. Further, I am convinced that injury at birth, of whatever nature or extent, is a possible, and not a probable, factor in the etiology.

From the hospital records of the past nineteen years I have collected 264 cases of wry-neck. During this time[5] upwards of 3400 cases of congenital and acquired club-foot came under observation—a comparison that will show the relative infrequency of the affection under consideration.

The following is a brief summary of some of the points of apparent interest.

Of the 264 cases 32 may be considered as congenital, with the reservation before mentioned. As to sex, 155 were females and 109 males, which would tend to disprove the statement that the affection is much more common in males than females. In 77 it might be considered as acute, and in 60 chronic, in 48 having existed for from one to twenty years.

Excluding congenital cases, the duration of the affection was mentioned in 137 instances.

The affected side was mentioned in 187 instances. In 98 it was on the right, and in 97 upon the left side, in contrast to the assertion that it is much

more frequent on the right than the left side. Early childhood is the time of greatest susceptibility, but ten cases are noted at more than eighteen years of age.

In 106 cases of acquired torticollis the cause seemed apparent. Of these nearly 50 per cent. might fairly be classed as from cervical gland irritation, often after some contagious disease.

Age and sex of patient when first seen:

The apparent causes of torticollis, as noted in the records, were:

	Cases.
Enlarged cervical glands	5
Suppurating cervical glands	22
" glands following scarlet fever	11
Torticollis following scarlet fever, condition of glands not noted	7
Torticollis following diphtheria	4
" " mumps	5
" " measles	1
" " sore-throat	4
Suppurating otitis	3
Toothache	1
From cellulitis of neck	2
	65

Other causes were:

	Cases.
Cicatricial, following burns	3
Caused by injury of the neck	14
Probably of congenital origin	32
	49

Torticollis was associated with

Rheumatism	9 cases.
Fever	3 "
Malaria	4 "
Total	16 cases.

Torticollis was associated with disease of the nervous system as follows:

Chorea	3 cases.
Epilepsy	1 case.
Cortical irritation	1 "
Hysteria	1 "
Infantile hemiplegia	1 "
Meningitis	1 "
Spasmodic torticollis	1 "
Total	9 cases.

That duration of the affection is in itself a very potent factor in prognosis is illustrated by the in-patient records of 39 cases; 17 were admitted when the deformity had persisted for less than six months. Of these 10 were cured, 4 were improved, and 3 were not improved. Of 15 cases of more than six months' duration none were cured, 6 were improved, and 9 were not improved.

It should be noted that with few exceptions these patients were treated at a time when operative interference was not recognized as an attribute of orthopedic surgery as practised at this institution, otherwise every recognized method of treatment seems to have been employed, in most instances for many months. Of four cases of long standing treated recently by open incision, one was cured, two nearly cured, and one improved, the average stay in the hospital being but three weeks.

It seems fair to assume that there is an actual arrest of development in a contracted muscle, and that the more persistent the irritation, the more rapid the growth, the more marked will be the deformity. To overcome the contraction of such a muscle it must be overstretched to a degree corresponding to the amount of previous shortening. In the neck this is almost impossible by mechanical means when the affection has become chronic in character. This affords the rational indication for treatment: to hold the head by some appliance in perfect position from the outset of the affection when rectification is easy, especially if it appears to be caused by the presence of inflamed glands, which may persist long after the original source of irritation has been removed, not alone because rest is the proper treatment for inflamed glands, or for the relief of the strain upon the nervous system of a painful deformity of this character, in itself an important factor, but that we may not have the deformity-habit with shortened muscles and fascia to deal with when active contraction is no longer present. The removal of enlarged or suppurating glands, especially if they lie about the motor point of the contracted muscle, should certainly be considered. As this often necessitates a division of the sterno-mastoid we may at once take away the cause and remedy the result by this procedure. My time will not allow me to speak of other causes of wry-neck or of general considerations in treatment which must be governed by the indications in the individual case. They are sufficiently described in works upon this subject.

The induration that follows muscle-rupture usually disappears in from two to six months; if deformity is present, greater than may be explained by the character and size of the tumor, it is probably of intra-uterine origin and should be treated on the principles that apply to that affection—and, with certain modifications, to the acquired form that has persisted for any length of time; that is, free and early division of all contracted tissues that do not rapidly yield to milder methods, followed by the careful after-treatment which all cases of this character require. From the evidence presented, I think we may conclude, contrary to the prevailing theory, that the causes of congenital wry-neck operate in a majority of cases before birth rather than during delivery. That acquired torticollis in very young children may be as persistent in duration and as disastrous in its results as the congenital variety—the age of the child, the persistence of irritation, the arrest of development in the contracted parts, and the rapidity of growth being the determining factors—and that here, as elsewhere, the prevention of deformity in the first instance, or its rapid rectification if seen in the later stages, should be the object of our therapeutic efforts.

TUBERCULOSIS OF THE BONES AND JOINTS.[1]

By A. H. LEVINGS, M.D.,
of Appleton, Wis.

From the time of Hippocrates many authors have given descriptions of joint-disease that are easily recognized as tuberculous. Richard Wiseman, of London, in 1734, gave what was probably the best description up to his time, calling the disease "white swelling." He thought the condition the result of scrofula. Benjamin Bell and R. Brown Chester believed that the tumor albus was due to two different causes—the one scrofula, the other rheumatism and trauma. In 1807 Samuel Cooper stated that in healthy well-nourished persons the prognosis of joint-inflammations was good, while in scrofulous individuals the tumor albus resulted. In 1842

[1] Read before the Wisconsin State Medical Society, June, 1891.

Rokitansky taught that the great majority of these tumors were due to tuberculosis of the synovial membrane. Then Virchow demonstrated that the worst forms of tumor albus, especially those of the knee, were due to miliary tubercles; and in 1865 R. Volkmann demonstrated the tubercles of tuberculosis in joint-disease.

Tuberculous processes in bone are usually seated at the epiphyseal ends of the long bones, in the vertebræ, in the spongy bones of the carpus and tarsus, and less frequently in the long bones of the hand and foot (spina ventosa). Bones are infected in two ways: First, the bacilli that have gained entrance to the blood and general circulation may be carried directly through the nutrient artery to the epiphysis of a long bone, and becoming arrested in some small terminal branch escape through the walls of the vessel, and form tubercles in the spongy tissue; or, second, small particles of caseous matter, usually in the lungs, ulcerate their way into a pulmonary vein, and are carried to the heart, and by the arterial system are carried to some small terminal artery in the epiphysis of a long bone, or in a spongy bone, in which they lodge and form a tuberculous deposit. (Krause.)

The election of the epiphyses of long bones and the short spongy bones as the usual seats of tuberculous deposit may perhaps be explained by the blood-supply. As growth takes place at the epiphysis, this part receives more blood than does the shaft. The bloodvessels are larger than those supplying the compact bone through the periosteum. The same may be said of the spongy bones. Bacilli or caseous emboli having been implanted in the epiphysis of a bone, form tubercles, and, coalescing, these produce nodules that may be the size of a hazel-nut or walnut. The nodules may be hemmed in by sclerotic bone and healthy granular tissue, and a cure effected, or softening and suppuration may sooner or later occur. The bone-cavity may be lined by a pyogenic membrane made up almost entirely of tubercles held together by fibrinous deposit.

Whether the surrounding bone is free from deposit, or there is no pyogenic membrane, it is in either case usually infected with caseous material, so that there is an easy means of systemic infection. Often the tuberculous nodule undergoes degeneration, and is separated from the surrounding bone by inflammation, resulting in a sequestrum. These sequestra may and often are found in the epiphyseal ends of the two bones entering into the formation of a joint. In a case of tuberculosis of the knee-joint, in which resection was recently performed, such sequestra were found in the outer condyle of the femur and in the head of the tibia, each about the size of a hazel-nut.

In cases in which the tuberculous nodes undergo softening and suppuration they generally, by a process of ulceration, reach the surface of the part through the periosteum, producing a fistula, or, breaking into the joint, infect the synovial membrane, giving rise to tuberculous synovitis, with perhaps destruction of the cartilage and caries of the bone-surfaces.

Disease of the short bones of the foot is common at all ages, while in children disease of the bones of the hand is rare. Caries of the ribs is more common than that of the flat bones, and is frequently a result of tuberculous pleurisy. In a case of tuberculous pleurisy, with fistula, recently operated on after the method of Schède, five ribs were found carious.

Tuberculous disease of the vertebræ usually involves their anterior surfaces. The vessels penetrate the vertebræ perpendicularly to their surfaces, and a growth of cells, in the form of granulation tissue, surrounds the vessels as they enter the bone, destroying it and producing cavities, usually of small size. Many of these may be formed in a single case; two or more may coalesce, forming a large cavity; in this way much of the anterior surface of a vertebra may be destroyed. The superincumbent weight of the body forces the vertebræ together, and the characteristic deformity of Pott's disease is occasioned. The disease may terminate favorably by a splint of bone being thrown out on the anterior surface of the vertebra, beneath the anterior longitudinal ligament; or suppuration may take place and the pus may follow the spine downward, and give rise to a large abscess in the abdomen.

Joints are infected in two ways: First, by a deposit that has formed in the epiphysis breaking through into the joint and infecting the synovial membrane; and second, by a primary infection of the synovial membrane. It is also thought that a joint may become infected from a deposit in the epiphysis through the lymphatics.

The tuberculous processes in the synovial membrane are of two kinds: In the one there is an abundant growth of tuberculous and connective tissue (granulation tissue); the synovial membrane is much thickened, with little tendency to caseous degeneration; there is usually but little fluid in the joint. In the other there is but little granulation tissue, but an abundant formation of pus, which may break through the capsule and give rise to a peri-articular abscess.

According to a table compiled by Krause, in 77 per cent. of all cases of tuberculosis of joints the disease commences primarily as a deposit in the bone.

Caries sicca. It is only recently that this form of joint-disease has been known to be of tuberculous origin. The disease commences in the synovial membrane, with the formation of little or no pus.

There is a thin layer of granulation tissue in the synovial membrane, which advances into the cartilages, destroying these, and often also the articular surfaces of the bones. This form of disease is usually found at the shoulder- or hip-joint.

Trauma is the most frequent exciting cause of tuberculous processes in bone. The predisposing cause is scrofula. Much has been written, regarding the relationship of scrofula to tuberculosis. An individual is scrofulous when there is a certain constitutional condition—a tendency to chronic inflammation and suppuration of particular tissues—even though he should be apparently perfectly healthy; while one should not be called tuberculous unless there is somewhere in the system a tuberculous process (Krause). Given a child predisposed to tuberculosis, having a scrofulous diathesis, not well nourished, a slight injury, a twist or wrench of a joint, a slight laceration of tissue with extravasation of blood, provides a favorable nidus for the growth of bacilli; and at this point a tuberculous inflammation is likely to be established. Now, a well-nourished person, without this predisposition, might receive a similar injury and escape a tuberculous process. If the injury is more severe—perhaps a luxation or a fracture—healing takes place, even in one predisposed, without the development of a tuberculous process. This is accounted for in the case of luxations by the fact that the rupture of the synovial membrane gives the fluids in the joint an opportunity to escape, thus relieving tension and the resultant irritation. In the case of fractures the cell-proliferation, which is very great, and that occurs as a part of the healing process, prevents the growth of the tubercle bacillus at the seat of injury.

Age is an important factor. Tuberculous processes in bones and joints are much more common in children than in adults.

When a tuberculous deposit has taken place in the epiphysis of a long bone or in one of the small bones, there will be more or less pain on pressure; and if the deposit approaches the periosteum there will at this point usually be edema. The affected joint is more or less painful on motion, and is to some extent fixed. The patient is indisposed to use the member. There is little or no fever, and usually no effusion into the joint.

Should the tuberculous process attack the synovial membrane there will usually be an effusion of serum or of serum mixed with pus. The temperature of the joint as well as of the body is increased. If pus forms, the joint becomes swollen; the symptoms are intensified by use of the joint, and with rest more or less disappear. One of the characteristics of the disease is the ever-changing character of its symptoms.

The swelling may be within or without the joint; if within it is the result of effusion or of the growth of granulation tissue, and occasions semi-fluctuation. The abnormal position in which an inflamed joint is held was by Bonnet ascribed to the effusion, the limb assuming the position allowing the greatest degree of distention of the capsule. To some extent this is true, but muscular contraction from irritation of the synovial membrane also plays an important part. The skin covering the joint is white ("white swelling"), and it is here and there marked with blue veins.

In many cases, especially in children, the prognosis of tuberculous processes in bones and joints is favorable. The granulation tissue becomes denser, is hemmed in by connective tissue which contracts and cicatrizes. If the process affects a joint this becomes more or less distorted and ankylosed, even in cases in which pus has formed. Healing may take place by absorption of the pus, or after its spontaneous discharge. Cases of Pott's disease in which a cure has been effected, with or without deformity, are familiar to everyone.

In other cases of tuberculosis of the bones and joints, in consequence of excessive suppuration, high fever and loss of appetite, especially if the process is in one of the larger joints, the patients become anemic, lose weight, and die without other organs becoming affected, but with the general appearance of phthisis.

Again, as in all cases of chronic suppuration, especially in bone, the patient may become albuminuric, suffering from amyloid degeneration or parenchymatous inflammation of the kidneys. One must conclude that as a result of suppuration in bone, chemical substances are produced, taken up by the lymph-channels, distributed through the blood, and in circulating through the kidneys produce amyloid degeneration. Tuberculosis of a joint may be associated with basilar meningitis, tuberculosis of the lungs, or acute miliary tuberculosis. This is especially common in children. These complications or associations may follow operation, as by resection or curetting a fistulous tract, a vein or lymphatic may be opened during the operation, and the germs gaining an entrance are distributed throughout the system.

In my own practice during the past year two cases of acute miliary tuberculosis have followed operations on tuberculous bone. One was a case of resection of the hip, in which the acetabulum was much diseased, and the other a case of curetting several of the tarsal bones and fistulous tracts.

Krause mentions several interesting cases: In one, a boy fourteen years old, strongly built, suffered from a tuberculous process in the lower end of the radius. An incision was made down to the bone, which was opened with a chisel, and the deposit cut

away with a sharp spoon. Everything progressed favorably until the fourteenth day, when the boy complained of headache. In quick succession all the symptoms of basilar meningitis appeared, and he died four weeks after the operation. The autopsy disclosed a tuberculous meningitis, as well as an eruption of fresh miliary tubercles in nearly all the internal organs. Nowhere was there a caseous deposit to be found. Acute miliary tuberculosis following an operation can only be attributed to the operation when an autopsy shows that there were no caseous deposits in the body.

TREATMENT.—The general system should be improved by means of nourishing food, fresh air, cold baths and tonics. If the joint is irritated or inflamed it should be put at rest. Nothing answers a better purpose than the plaster-of-Paris cast. It not only fixes the joint, thereby relieving it of the irritation of motion that tends to keep up the inflammation, but it also exerts equable pressure, thereby maintaining the superficial circulation.

When a joint—the knee or hip, for instance—is much inflamed, extension should be applied, especially if there are spasmodic muscular contractions. This relieves the joint-surfaces of undue pressure, and prevents the spasmodic muscular contractions that are not only injurious, but also prevent sleep and wear the patient out with pain. In Pott's disease of the spine, Sayre's plaster-of-Paris jacket, with the jury-mast in suitable cases, produces the necessary extension and fixation, and in the great majority of cases will effect a cure. In all cases of tuberculous joints the cure may be but temporary; there is always danger that some trauma, a twist or a wrench, may bring the latent and apparently healed process into new life. It is probably true, however, that a considerable number of cases of this class are due to new infection, and not to the rekindling of the old inflammation. In cases of cure, with false or true ankylosis, even if the position of the limb is not good, the greatest circumspection should be used before the ankylosis is broken up, as the resultant injury may light up anew the old tuberculous process.

The treatment of tuberculous joints and tuberculous abscesses with iodoform-glycerin injections was formulated by Billroth and Mikulicz. A trochar is thrust into a tuberculous joint containing pus, the pus allowed to drain off, and the joint is washed out with a ten per cent. solution of boric acid. A ten per cent. emulsion of iodoform in glycerin is then injected into the joint. Krause gives the maximum quantity that should be injected at a time as 100 grams (3 ounces). After the injection, the joint is freely moved in every direction for the purpose of bringing the iodoform in contact with every part of the joint-surfaces. In cases in which suppuration has not been established, the washing out may be dispensed with. The injections are made every four weeks, and both in diseased joints and in cold abscesses are often followed by the most happy results. The iodoform applies itself to the internal wall of the abscess, destroying the tuberculous tissue and stimulating a growth of healthy granulating tissue that cicatrizes. Bruns and Nauwerck examined the wall of a tuberculous abscess one week after an injection of iodoform, and found that the tubercle bacilli had disappeared, and that healing was taking place.

The following case well illustrates the beneficial effects of iodoform injections:

E. H., three years old, was brought to me with Pott's disease of the lower dorsal and upper lumbar vertebræ. There were lameness and dragging of the right leg, and flexion of the thigh on the pelvis. There was a continual elevation of temperature. Sayre's plaster-of-Paris jacket was applied, and worn for four years, being renewed every three months. At the end of two years, when a jacket was being applied, a swelling of considerable size was noticed on the right side of the spine below the ribs. At the end of three months it had increased considerably in size, and a small trochar was thrust into it, and one and a half pints of pus obtained. Three ounces of iodoform emulsion were injected through the canula into the abscess cavity. Five weeks later one pint of pus was withdrawn and iodoform emulsion injected. Eight weeks afterward six ounces of serum, almost entirely free from pus, were withdrawn The swelling then entirely disappeared, the boy grew fat, lost his lameness, and has been perfectly well since.

Billroth has recently recommended free incision of abscesses, the removal of all diseased tissue with a bit of iodoform gauze, and the use of the sharp spoon for carious bone and fistulous tracts; the divided fascia and muscles are then united with interrupted sutures, and the skin with a continuous suture, leaving an opening through which to fill the cavity with the iodoform emulsion. The results are said to have been favorable.

What the final verdict of the profession will be, as regards the healing power of tuberculin on tuberculous processes in bones and joints, it is difficult at present to determine. That it is not the great panacea for all tuberculous processes that had been hoped must be apparent to all that have used it. That it is without benefit, and in acute cases with high fever even harmful, I believe is also true. But in chronic cases, especially where fistulous openings exist, it may and probably will prove of great help to the surgeon, either with or without a subsequent operation.

For the primary tuberculous deposit in bone, an early operation is indicated, to prevent, if possible, infection of surrounding bone, neighboring joints,

or, what is still more to be feared, the occurrence of acute miliary tuberculosis. If a fistulous tract exists, it leads the way to the diseased bone, which with the greatest possible care should be cut away with a sharp spoon, removing all the diseased tissue, both in the bone and in the fistulous tract. If possible, the operation should be performed on a bloodless limb, to reduce the liability to infection through the veins and lymph-channels to the minimum.

Resections of the synovial membrane or of the bones should only be undertaken when it is apparent that more conservative methods will not succeed. Better results from conservative methods may be expected in children than in adults. If possible, resection of an epiphyseal cartilage should always be avoided in children, since it prevents the proper growth of the limb. In cases of suppuration within a joint, with high fever, loss of weight and increasing weakness, the joint should be opened and all diseased tissue removed. If the disease is confined to a portion of the synovial membrane or cartilage, only these parts should be removed. Resections proper should be reserved for more extensive disease, and amputation for extreme cases, in order to save life.

THE SUBCUTANEOUS USE OF HYDRARGYRUM FORMAMIDATUM SOLUTUM IN SYPHILIS.[1]

By ROBERT B. MORISON, M.D.,
DERMATOLOGIST TO JOHNS HOPKINS HOSPITAL AND DISPENSARY.

In 1882, Liebreich, of Berlin, suggested the use of a subcutaneous injection of a 1 per cent. solution of a preparation that he called hydrargyrum formamidatum. His claim for its usefulness in comparison with other preparations was that, being a neutral solution, there was little or no danger of abscesses following its injection, and that there would be less pain. In order to learn if the solution is properly prepared, it should be tested with an aqueous solution of iodide of potash, 1:20, added drop by drop: no red color, or red precipitate, should appear, but only a yellow cloudiness. It should have a neutral reaction, and should not precipitate a 1 per cent. solution of albumin.

The injections are made deeply into the gluteal muscles, the patient standing, the needle being introduced obliquely into the muscles from below rather than at right angles to them. The number of injections to be given will vary in different patients. Usually twenty are sufficient to effect a cure, or at any rate to show if the method is to be of any use. In acute syphilis the injections begin to show their good effect after the fourth or sixth, but a longer time is required in chronic cases. They may be given every day, every other day, or twice a week. If there be no hurry in the case, one every other day is sufficient.

The pain varies in different persons, and even after different injections in the same person. It begins almost immediately, and the side injected remains sore for some hours. I inject first one buttock and then the other. I have never made the injection in any other part but once, and this was into the thigh of a woman. This, though not followed by an abscess, was very painful for several days; this method was, therefore, not repeated.

I will give a history of a few of my cases:

Case I.—T. J., aged sixty years, married, came to me in January, 1884. He first had signs of syphilis ten years before, and had been thoroughly treated with mercury and potash at the time. All symtoms disappeared within a year, and since then his wife has given birth to one apparently healthy child. When first seen by me the left hand was swollen and indurated, there being no pitting on pressure. The skin was not pliable or elastic, and the swelling and induration extended up the arm to the elbow. This condition of the arm had been coming on for many months, the size of the hand gradually increasing and the swelling extending further up the arm until the limb could be very little used, and was carried in a sling. There were no pain, redness, or appreciable swelling of the lymphatics. On the palms of both hands were large and small characteristic maculæ with whitish crusts upon a reddened base. The soles of the feet showed similar spots, with a small, indolent ulcer between the little and next toe of the right foot. There was chronic catarrh of the throat and nose. I put him on the usual formulæ of mercury and potash, trying them together and separately and in different combinations until he refused to take any more. No good had been gained by this treatment. I then commenced the subcutaneous injection of 15 ♏ of a 1 per cent. solution of hydrargyrum formamidatum every other day. The injections were made deeply into the gluteal muscles, the right and left sides being taken alternately. After the eleventh injection he began to show evidences of mercurialism, both in the odor of the breath and the puffiness of the gums, and the injections were stopped for a week. The buttocks were sore, but there was no induration anywhere, and no symptom of an abscess. Six more injections were then given, one every day, when they were stopped altogether. This made seventeen injections in all. After a week's intermission the spots on the hands and feet had entirely disappeared, and the ulcer of the toe had healed. The condition of the mouth was improved, and in another week, without further treatment, had even still further improved. The induration of the hand and arm was much lessened, so that the sling could be given up, and the hand used quite naturally. I followed this case for six subsequent years, and saw no return of the symptoms described. The man died as a result of chronic alcoholism.

[1] Read at the meeting of the American Dermatological Association, held in Washington, September 22–25, 1891.

CASE II.—January 2, 1884, K. B., aged forty-five years, unmarried, consulted me, denying any history of chancre or venereal disease. There was the eschar of a suppurated gland in the left groin, the cause of which he could not or would not explain. The palms and soles of both hands and feet were almost entirely covered with a whitish, slightly scaly eruption. There was no itching, but there was intense dryness. Some of the fingers and toes had ugly-looking fissures between them. There was a slight eruption of a similar kind on the outside of both elbows, and a few copper-colored spots scattered over a very hairy chest. The trouble on the hands had existed for ten years, and was then worse than ever before. The patient was a high liver, a popular diner-out, and "a great man for women." The condition of his hands was such that he always wore gloves, and many comments upon this eccentricity from high and low society worried him. He had tried many remedies for eczema, both internal and external. I persuaded him, with much difficulty, to try the subcutaneous injections of mercury, besides giving him a mild mercurial salve to rub upon his hands at night before putting on his gloves.

On February 2d the first injection was made, and it was repeated every other day until twenty-one had been given. During the treatment I could not keep my patient from any of his many excesses, and he would not agree to the idea that he had ever had syphilis. The result was unfortunate in one sense, because, instead of the hands getting well, it was the feet, elbows, and chest that did so, while the hands remained very much the same. He told me that he was tired of the injections, and was going to try someone else not a regular practitioner. I met him within the last two months, and he was still wearing his gloves.

CASE III.—In November, 1885, H. L., aged twenty-three years, unmarried, son of a physician, was brought to me by his father for a diagnosis. He denied ever having had a chancre, or ever having been exposed to the danger of one. He was persuaded to strip off his clothing, when there was disclosed a perfectly typical universal roseola. The remains of an indurated chancre was found upon the prepuce. The young man was a graduate druggist, and, it was found out, had been dosing himself with mercury, potash, sarsaparilla, and other things, until his digestion was much impaired. All medicine was stopped, and he was put upon the injection of 20 ♏ of hydrargyrum formamidatum every day. After receiving ten, they were stopped for four days and then continued. After the fourth injection the roseola faded rapidly, and had disappeared after the tenth. They were continued on account of sore-throat and of mucous patches in the mouth. After the sixteenth injection he stopped coming, contrary to my advice, although all his symptoms had disappeared.

A year later he came to ask me if he could get married, and was much disturbed when I told him he ought not to do so. His symptoms were enlarged glands and chronic sore-throat, and I advised him to go through another course of injections. This he did not do, but within a month I received cards announcing his wedding. Four years after this time I met his father, who told me that his son had a child three years old, which was apparently healthy.

CASE IV.—In May, 1886, L. J., aged thirty-two years, unmarried, thin, anemic, nervous, and dispirited, was brought to me in consultation. He confessed that he had had a chancre two years before, followed by an eruption. He had been in the hands of many physicians, and at last had put himself under the charge of a quack, who packed him in moist clay and kept him thus for days at a time. He came to me in bad condition, with broken-down gummata on his neck, face, and right leg, and with a chronic sore-throat. A day or two afterward a severe attack of neuralgia of the left side of the head was duly followed by one of the worst attacks of herpes zoster I ever saw. The eruption extended from the eyebrow over the left side of the head as far down as the ear. Morphine was the only measure that relieved the pain, which lasted for three weeks. The vesicles became pustules, and finally left deep, copper-colored scars that have never faded away.

Injections of mercury were begun after this attack, and given every third day, until ten had been given. The results were decidedly beneficial, but they were stopped on account of my absence from town for six months, and his desire to go to the Hot Springs of Arkansas. He is at present as well as a delicate man can be.

CASE V.—In October, 1890, S. W., aged forty years, unmarried, was brought to me in consultation. He was a tall, muscular, healthy-looking man, who confessed to having had a chancre two years before. He had been put through the regular course of mercury and potash, and was then suffering from dyspepsia and intolerance of any drugs. There were *psoriasis palmaris et plantaris*, moist condylomata on the scrotum, with one obstinate mucous patch on the right side of his tongue.

Like others he had gone the round of regular and irregular physicians, so that something other than the usual course had to be pursued. Subcutaneous injections were begun, the dose being 20 ♏ three times a week. His tolerance for mercury was great; he received sixteen injections before much improvement was manifest. They were then increased to 30 ♏ three times a week. After receiving thirty, all the syphilitic symptoms had disappeared, and he was told that he needed no more. He insisted, however, that as he had not been so well since he first contracted the disease, he must have further treatment. He came twice a week at first, then once a week, then once in two or three weeks, until he had received over a hundred injections. I have not now seen him for nearly six months.

CASE VI.—In January, 1891, W. A., aged thirty-three years, unmarried, consulted me, having had a chancre nine years ago. He had been treated in the usual way ever since with mercury and potash. One of our throat specialists, who was treating him for syphilitic sore-throat, sent him to me to see his hands and feet. The palms and soles were covered with a macular, syphilitic eruption—so-called psoriasis. There were also several indurated papules

upon the scrotum. After stopping all medicine by the mouth, he was put upon the subcutaneous injection of 20 m of hydrargyrum formamidatum every other day. They had to be discontinued after the sixth injection, because he was clearly becoming ptyalized. He had to leave town at this time, and I did not see him for several weeks. While away he took no medicine, and when he reappeared his hands and feet had cleared up, the papules on his scrotum had disappeared, and he had no trouble with his throat. I wanted to stop the injections, but he insisted upon going on with them from time to time, as opportunity afforded, until he has received nearly fifty. Like the preceding case, he feared another relapse such as he had previously experienced.

Besides these and many other cases in private practice, the injections have been used by me in dispensary practice, and with equally good results. There are, however, some cases of syphilis that at first seem to defy any treatment. I call to mind one case of malignant syphilis in a man aged twenty-three, which every form of mercury or potash failed to affect. The large tubercular syphilide that covered the patient's body from head to foot was only aggravated by the injections. It was necessary to put him on cod-liver oil and tonics alone, and to dress his whole body in soothing salves until the acute stage had passed. In this case subcutaneous injections did more harm than good, were very painful, and, if persisted in, might have been followed by abscesses. The patient was ultimately able to take ¼ gr. of salicylate of mercury three times a day, and is slowly recovering. On the other hand, a stable-boy, nineteen years old, with an acute macular syphilide, was so quickly cured of it that he stopped coming to the dispensary altogether. He was seen several times on the street and told to come, but laughingly said that there was nothing the matter with him.

In summing up the results of my experience with these injections, I feel that I may say that in them we have a valuable addition to the list of remedies in treating syphilis; that there is no danger of abscesses following their use, since I have never seen one after having given as many as a thousand injections; and, lastly, that in many obstinate cases they can frequently be relied upon to accomplish what no other treatment has accomplished.

CLINICAL MEMORANDA.

LIGATION OF THE EXTERNAL ILIAC ARTERY FOR FEMORAL ANEURISM.

By JAMES K. YOUNG, M.D.,
INSTRUCTOR OF ORTHOPEDIC SURGERY, UNIVERSITY OF PENNSYLVANIA; ATTENDING SURGEON, ORTHOPEDIC DEPARTMENT, UNIVERSITY HOSPITAL, PHILADELPHIA, ETC.

The following case, recently under my care, presented so many features requiring surgical judgment, that although the result was unfortunate, lessons remain and may be of interest to others who may be similarly placed.

History: The patient, S. A., forty-eight years of age, was a large, muscular, colored male, born a Virginian slave, of healthy parentage. About January 15th, following an injury, a swelling developed in the right femoral region, which he described as nodulated, pulsating, and painful. About the same time his leg swelled and the sole of the foot and toes were numb and tingling. The swelling developed slowly, until it had assumed enormous proportions. On examination, in consultation three months later (April 15th), the following condition was observed: The patient was much emaciated, the expression anxious; the right thigh was enormously enlarged and intensely hard, except at its upper third, where it presented a large fluctuating swelling, the upper portion of which overlapped and obliterated the femoral fold. An expansile pulsation and marked bruit were present. The scrotum was slightly swollen and pushed far backward. The patient denied syphilis. The coxo-femoral articulation was normal. The thigh was flexed upon the abdomen, and the patient for three weeks had been unable to sleep in a recumbent position. All the superficial vessels were atheromatous. The situation of the aneurism, very high up in the Scarpa's triangle; the uncertainty of its origin, whether from the common or superficial femoral, rendered it an unsatisfactory case for compression, and its size forbade the possibility of cure by ligation of the superficial femoral below (Brasdor's operation ?). There remained the ligation of the external iliac, and this the patient consented to. Three days later he was transported thirty-three miles to the hospital, and while being transferred to a carriage before entering the train he experienced a sudden faintness, with a relief from pain, and was able to extend the thigh. It is probable that the aneurism was diffused at this time.

On the day following admission (April 19th) his condition was as follows: Pulse 100, temperature 100°, respiration 56. The thigh was hard; no pulsation or bruit could be distinguished at this time or afterward, and the temperature of the foot and lower third of the leg was below the normal. The urine contained no albumin. The entire leg was gangrenous. Here, then, was a man of forty-eight, with atheromatous arteries, a large, diffused femoral aneurism, dry gangrene of the leg, and in a condition of profound shock. Evidently there was nothing to do but to wait for reaction.

Five days later, the condition having improved (temperature 100°, respiration 40, pulse 104), it was decided to ligate the external iliac artery, control the return circulation by an Esmarch tube applied below, to open the aneurism, turn out the clots, and thoroughly pack the wound. Subsequently amputation was to be performed. Assisted by Dr. T. S. K. Morton, Dr. John B. Deaver, and Dr. Baldwin, the resident, in the presence of Drs. Wilson, Neilson, Stern, H. C. Deaver, Brinkman, McGee, and others, the external iliac artery was readily secured near its proximal position, at which point the coats of the vessel were normal. The sac was then incised and about a quart of clotted blood removed. The vessel in this locality was atheromatous. There was no hemorrhage either from the incision or from the sac; the patient reacted quickly, and the ligation wound united by first

intention in three days. The duration of the operation was sixty-five minutes. The condition was decidedly improved (temperature 98⅘°, respiration 36, pulse 102), until the following night, when, during the absence of the nurse, the patient left his bed and walked about ten yards, where he was subsequently found in a condition of syncope. Subsequently his pulse was more rapid, and difficult to obtain in the radials, his respirations were increased, and the heart-sounds over the precordia were muffled. Notwithstanding these untoward symptoms, the condition improved for three days, and the line of ulceration formed obliquely upon the perineal region. At the end of this period the general condition was not quite so favorable (temperature 100°, respiration 40, pulse 104). A line began higher up on the inner aspect of the lower third of the thigh, and amputation was decided upon. The thigh was amputated by a short anterior flap communicating with the aneurismal sac, and a long posterior flap.

Though somewhat shocked by the operation, the condition improved, and the temperature became normal—98.4°. The wound did well and the flaps united firmly, but required to be irrigated daily with an antiseptic solution on account of the communication with the sac. The general condition gradually failed, delirium of a peculiar character supervened, with convulsions, the patient snapping and biting at everything, and three days after the amputation death ensued.

On post-mortem examination, the inguinal (ligation) wound was completely and firmly united, and the flaps were firmly united, except where the drainage-tubes made their exit. Only the heart was examined, and both ventricles were almost completely filled by large, yellow (ante-mortem) clots, which were evidently the cause of death. These probably began to form on the second night subsequent to the ligation. But for this additional and irremediable condition it is probable that the cure would have terminated favorably, notwithstanding the many and difficult complications met.

UNUSUAL MODE OF TRANSMISSION IN A CASE OF DERMATITIS VENENATA.

BY J. ABBOTT CANTRELL, M.D.,
DERMATOLOGIST TO THE PHILADELPHIA HOSPITAL.

MARY G., thirty-four years of age, was admitted into the general wards of the Philadelphia Hospital on September 24, 1890, and was removed on October 26th to the maternity ward, where she was delivered of a male infant. She continued well until the 29th, when she complained of an itching and burning sensation of the abdomen, which showed an inflamed surface, covered with vesicles and bullæ.

I subsequently learned that two nurses, one from the surgical and the other from the maternity ward, left the hospital at 2 P.M. on the 26th instant, taking a stroll through an adjacent cemetery gathering leaves and bringing a number back with them. Among the leaves were a number of ivy leaves, but this fact was not known by the nurses at this time. At 4 P.M. some of these leaves were placed on a table in the maternity ward, but in a separate compartment from that in which the patient was confined. They remained until the morning of the 28th, when they were thrown away. The nurse stated that after her return her hands were washed several times with ordinary soap and water, and when dressing the young mother her hands came in contact with the skin of the abdomen, and thus probably conveyed the ivy poison to the spot affected, as her hands, which at this time were apparently not affected, showed the eruption in a day or two. It also appeared on the abdomen of the patient at about the same time.

I saw the patient for the first time, upon invitation of Dr. Barton Cooke Hirst, the obstetrician on duty, on October 29th, two and one-half days after her confinement. I found situated upon the abdomen and surrounding the umbilicus, having a radius of full five inches, a vesicular and bullous eruption, with the whole surface swollen and edematous and covered with the characteristic yellowish-brown, gummy discharge of dermatitis venenata. Upon inquiry, I then learned the foregoing facts. After using a solution of fluid extract of grindelia robusta, two drachms to the pint of water, for about a week, the eruption entirely disappeared.

From a search through the literature of the subject I can find only one parallel case—that referred to in an exhaustive work on the subject by Dr. J. C. White, of Boston. This patient was a child of six years, that had received the poison from a servant who was himself unsusceptible to the poison. This servant had been clearing weeds, among which were some ivy vines from the garden surrounding the house, after which he had washed his hands thoroughly several times with vinegar and soap after entering the house. In the afternoon he took the child to a pond for a bath, holding him by the armpits, and afterward rubbing the axillæ and the back. In two or three days deep ulcers formed in both regions.

The point of interest in these cases is the mode of contracting the disease. It has been known for years that the poison may be absorbed by handling the leaves or by being near the vine. In the latter case there seems to be an idiosyncrasy to the disease. I believe the case of Dr. White and this one are the only cases recorded wherein the disease was contracted by the mere handling of a person affected.

SPINA BIFIDA.

BY T. A. HARRIS, M.D.,
OF PARKERSBURG, W. VA.

IN THE MEDICAL NEWS of August 8, 1891, is an article by Dr. E. P. Hurd, on the "Excision of the Spina Bifida," which recalls an operation I performed on the 23d of July, 1891, for this condition. I was asked by a country friend to see a case of spina bifida in a child about five days old. I found in the lumbar region a prominence about the size of a hulled walnut, crowned by a thin membrane. This, my friend Dr. Pricket had punctured with a sharp bistoury, allowing a small amount of serous fluid to escape, though there was no discharge from it when I saw it. The child was in vigorous health without any paralysis of the lower extremities. The body of the prominent mass consisted of integument, and was slightly pedunculated.

As a test I first tied an ordinary cord tightly around the base of the tumor. The only effect was to give the child very decided pain, certainly not paralyzing its

lower extremities, as was evinced by very decided kicking. I concluded that the spinal cord was not involved in the tumor. Removing this cord I then passed my knife around the base of the tumor, cutting through the integument, and then tied a silken cord around it, drawing it very tight, burying it in the cut I had made in the integument. This effectually shut off all circulation in the tumor, and cut off all communication with the spinal canal. I then freely scarified the membrane and the top of the tumor to allow free discharge of any fluid or blood contained in it. My suggestion to Dr. Pricket was that in four or five days he should put on another tight ligature. This he did, and in about ten days the entire mass fell off, leaving a sore spot about as large as a nickel, which in two weeks thereafter was healed, sound and well, leaving the child in apparent health. I do not think there was more than one (the last lumbar) vertebra involved. My expectation is that with the growth and development of the child the laminæ will practically close the space. I made no attempt to dissect out the membranes, but contented myself with so ligating the sac as to shut off all communication with the spinal canal, and trusted to the inflammatory action set up by the ligature to close permanently the communication with the canal. It would have been a much nicer operation to have cut off the mass and to have brought its edges together, but I did not believe that any stitches or plasters I could use would suffice to keep out weeping from the spinal canal sufficient to prevent union of the cut surfaces, having done this on the 23d of July, and immediately after August 8th. Seeing the article by Dr. Hurd has prompted me to report my case and thus to add another to the rare cases of recovery from this not very uncommon defect. I also wish to raise the question whether in the future active measures may not prove more effective in these cases than temporizing measures have in the past.

A CASE OF INTRA-CRANIAL HEMORRHAGE; AUTOPSY.

By E. KELL, M.D.,
PHYSICIAN TO W. H. HOSPITAL, BLACKWELL'S ISLAND.

J., a laborer, twenty-eight years old, came under observation August 29th, at 3 P.M., suffering from alcoholism and a contusion over the left eye. The man was rational. At 5 o'clock, he suddenly became unconscious, and the left side was involved in active convulsive movements. The face was flushed, the pulse 100, the respirations 24. The head was turned to the right, the right arm flexed across the chest, with the hand closed, the right leg extended; both were motionless. The right pupil was dilated and slowly reacted to light; the left was contracted and failed to react. There was no vomiting or hemorrhage from the nose, mouth or ear.

August 30. The temperature was 99°; the pulse 70, full and bounding; the respirations normal. The right pupil appeared normal; the left was still contracted, with a feeble reaction to light. The right arm became relaxed, and when raised fell to the side. The left arm and leg still displayed a tendency to spasm. In the afternoon the patient muttered a few indistinct words. He took medicine given to him.

31st. The paresis of the right arm and leg became more decided. The left pupil was still contracted. The knee-jerk on the right was enfeebled, on the left exaggerated.

September 1. The patient could, when aroused, answer questions in an indifferent manner.

2d. There were ptosis on the right and relaxation of the same side of the face.

4th. The temperature was 101°, the pulse 104, the respirations 20. The patient made no reply to questions.

5th. The temperature was 105°, the pulse 135, the respirations 36. There were no additional developments prior to death.

The man had been a syphilitic. During his illness he had passed an excess of urine. The bowels were regular.

At the autopsy, evidences of a contusion over the left eye were found. The lungs were congested, the heart fatty, the liver fatty and congested. There was chronic parenchymatous nephritis, with acute congestion of the kidneys. The cerebral meninges were congested. Over the entire right hemisphere of the cerebellum was found a clot formed of blood poured out from rupture of the middle meningeal artery, the result of a fracture extending from the right foramen lacerum medium through the foramen spinosum, with separation of the squamo-sphenoidal suture as high as the pterygoid ridge. The interesting question arises: Why was not the hemiparesis on the left side?

CURRENT LITERATURE.

THE INFLUENCE UPON THE CHILD OF MEDICAMENTS ADMINISTERED TO A NURSING MOTHER.

Schling (*Revue Obstét. et Gynécol.*, No. 4, 1891) has made a series of observations upon children, to the mothers of whom various drugs were administered. If the infant was not put to the breast sooner than an hour after the administration to the mother of from thirty to forty-five grains of sodium salicylate, the salicylate was found in the urine of the infant. At the expiration of twenty-four hours not a trace could be found. If the infant was put to the breast too soon after the administration of the drug, not even a trace could be found. The elimination of the medicament took place simultaneously in both mother and infant.

Similar results were obtained with potassium iodide. In the infant, the elimination lasted for seventy-two hours; in the mother for forty-four hours. At the end of twenty-four hours, the mother's milk still contained potassium iodide.

When potassium ferrocyanide was administered, the reaction was evident in the maternal urine, but no trace could be found in the fetal urine.

When iodoform was for a considerable time employed by topical application to vaginal and vulvar wounds in women in childbed, iodine was, as a rule, found in the milk and maternal urine, but not constantly in the urine of the fetus.

The transmission of mercury to a nursing child through the milk is slight and may be irregular.

The influence of the nourishment of the mother, that is the food ingested, appears to be *nil*. Nurses may

with impunity be permitted to partake of acids (lemon, vinegar, etc.).

Of narcotics, the ingestion of the tincture of opium, in doses of from twenty to twenty-five drops, has in some instances been followed by prolonged sleep on the part of the infant, while in others neither prolonged sleep nor constipation was observed. After the administration of morphine hydrochlorate, in doses of one-eighth, one-sixth, one-fourth, and one-third of a grain, nothing in particular was noted in the child. Chloral, in doses of from fifteen to forty-five grains, brought about sleep of moderate duration in the case of the mother, without any action upon a strong and vigorous infant. When atropine sulphate was administered in medicinal doses subcutaneously to the mother, dilatation of the pupil was observed in the infant, disappearing in twenty-four hours.

In a large majority of cases, the milk of a woman with fever has no influence upon her infant. Except in rare instances of grave illness in the mother, with a persistent temperature of 40° C. (104° F.), the infant does not present the symptoms of the mother. In a case of mammitis, the passage of micrococci from the breast of the mother to the digestive apparatus of the infant has been observed.

PHENOCOL HYDROCHLORATE; A NEW ANTIPYRETIC AND ANTI-RHEUMATIC.

PHENOCOL hydrochlorate, the hydrochlorate of amido-acet-para-phenetidin, is a white, finely crystalline powder, soluble in about sixteen parts of water at a temperature of 62° F., the solution having a neutral reaction. When crystallized out of hot water the crystals resemble the cubes of antipyrine; when crystallized out of alcohol, in which it is readily soluble only when hot, the crystals are needle-shaped. Pure phenocol is separated from a solution of the salt by ammonia, potassic hydrate and potassic carbonate. It appears as white felt-like crystals, with one water of crystallization discharged. The melting point of the water-holding base is about 203°, when deprived of its water, 212° F. The hydrochlorate is preferable for use on account of its solubility.

According to Professor Kobert, of Dorpat, phenocol is non-poisonous even to the blood. Professor von Mering gave 22 grains to a rabbit without producing any symptoms. His observations upon patients with typhoid fever and pneumonia have shown that phenocol hydrochlorate is a suitable antipyretic, which in doses of 15 grains lowers the temperature about two degrees, and has not been observed to give rise either to collapse or to cyanosis. Sweating was not more decided than after large doses of antipyrine. Fifteen grains of phenocol are said to lower temperature as effectively as 20 or 30 grains of antipyrine, or 10 or 15 grains of phenacetin. The hydrochlorate is also said to possess power as a nervine and as an analgesic in neuralgias.

Hertel has employed the hydrochlorate as an antipyretic and anti-rheumatic. He gave it in solution in water in doses of from 7½ to 15 grains. In four cases of phthisis, in which the remedy was employed as an antipyretic, the temperature was sometimes lowered, but not very decidedly; more frequently it was unaffected. The remedy, however, caused no disturbance of the circulation, respiration, or digestion. When the temperature was lowered, the effect was transient; the subsequent rise was unaccompanied by chill or sweat. The urine presented a dark-brownish to blackish color, which deepened on exposure to the air. Indican and hydrobilirubin were always present. The adding of a solution of ferric chloride caused the dark color to become still deeper, concentrated sulphuric acid again somewhat clearing up the color, which did not disappear, but by transmitted light displayed a peculiar greenish hue.

In three cases of acute articular rheumatism, phenocol hydrochlorate appeared to be of decided service in lessening the joint-pains, after antipyrine, sodium salicylate, phenacetin and antifebrin had failed; but it exerted no influence upon the temperature. In a severe case of gonorrheal rheumatism, it had no effect either upon the fever or upon the joint-trouble. No injurious action upon the kidneys was evident. The remedy appears to be speedily excreted—at least the reaction of the urine with ferric chloride no longer occurs twelve hours after the administration of the phenocol hydrochlorate has been withdrawn.—*Deutsche medicin. Wochenschrift*, No. 15, 1891.

THE TREATMENT OF RHACHITIS WITH PHOSPHORUS.

VOUTE (*Bull. Gén. de Thérap.*, No. 14, 1891) states that while it is true that the calcareous salts are indispensable during the period of bone-development, it is also true that rhachitic bones are deficient in lime-salts, and that the stools of a rhachitic child contain a much larger quantity of lime-salts than those of a healthy child; it would be unfair to conclude either that the nourishment contained a deficiency of the salts of lime, or that these were dissolved by the lactic acid formed by some derangement of digestion. The constant presence of pure lactic acid in the normal stools of healthy, nursing infants has been demonstrated. Besides, rhachitis is sometimes found in infants well nourished and raised hygienically. The inference is that in consequence of the existence of rhachitis the lime-salts are not assimilated in sufficient quantity. This is in accord with the view that the activity of the plasma occasioned by the great formation of bloodvessels retards the deposit and favors the solution of the lime-salts.

It is held that the characteristic of rhachitis is found in an abnormal hyperemia and formation of bloodvessels in the bone-forming tissues, and that the symptoms are but mediate or immediate sequelæ. Among the causes that lead to such a condition are abnormal processes in the stomach, which are apt either to give rise to the excitants that provoke inflammation, or to irritate the bone-forming tissues, as a result of which there is an increased proliferation of these tissues, followed by the development of bone deficient in lime-salts.

It has been demonstrated that small doses of phosphorus exercise a beneficial influence upon the structure of new bones. This suggested the employment of phosphorus in the treatment of rhachitis. The results have been extremely gratifying.

Adopting the suggestion of Hénoch that the dimensions of the large fontanelle afford the simplest method of determining the existence of rhachitis, Voute examined

the fontanelles of all infants brought to his polyclinic. For this purpose he used graduated callipers. A great difference exists between the dimensions of the fontanelle in healthy infants of the same age, so that it is difficult to establish a mean. The measurements of the fontanelles were used as an index of the effects of treatment. Of 1146 cases, up to the age of twelve years, treated at his polyclinic for children, 132 were cases of rhachitis—a little more than 11½ per cent. In 40 of these 132 cases a sensible amelioration resulted from the employment of phosphorus. In 10 cases the results were uncertain or the duration of the treatment protracted. In 13 cases intestinal disorders were produced and the remedy had to be withdrawn. Forty-two children did not return after the first prescription, and cannot, therefore, be considered, while in 27 cases a different treatment was pursued. The formula employed contained $\frac{1}{300}$ grain of phosphorus in ℥ss of cod-liver oil, administered night and morning.

DIAGNOSIS OF MALARIA IN INFANTS.

Hochsinger maintains that intermittent fever is far more frequent in sucklings and young children than is generally supposed, particularly in Vienna. Children during the first two years of life are especially prone to it. The observations of Hochsinger confirm those of the French authors, who state that the disposition to malarial infection is incomparably greater in childhood than at any other period of life. Intermittent fever in children is rarely diagnosticated, because the disease runs an atypical course. The initial chill is always, the sweat nearly always, absent in sucklings and young children; intermissions between the febrile attacks are not clearly marked, the temperature remaining from one to two degrees higher than normal; the febrile curve is more like that of a remittent than an intermittent fever.

The digestive and respiratory systems of the child soon show the effects of the disease. The child runs down, loses flesh, becomes anemic, and of a sallow color. The symptoms may be ascribed to gastro-intestinal catarrh, or to dentition; or tuberculosis may be suspected. If quinine should be given, improvement and recovery take place with surprising rapidity. Mild forms of the disease may disappear spontaneously, or under the influence of a change of climate.

Prior to the discovery of the plasmodium of malaria Hochsinger frequently made the diagnosis by a study of the temperature-curve, the condition of the spleen, the color of the skin, the history of the case, the restlessness and the manifold nervous symptoms, coupled with the knowledge of residence in a neighborhood possibly malarial. In such cases, from seven to twelve grains of quinine were given, and nearly always effected a cure. Since systematic examinations have been made the plasmodium has been found in twenty-four cases of intermittent fever in children. Half of the cases were in sucklings, the youngest being three months old.

To examine the blood for plasmodia, cover-glass preparations are made, dried in the air, and subsequently fixed by immersion for twenty or thirty minutes in a mixture of equal parts of alcohol and ether. They are then stained with a solution consisting of about three ounces of a strong, aqueous solution of methyl-blue, to which a few drops of absolute alcohol and then seven and a half grains of eosin dissolved in water are added. The solution is then sterilized by boiling for half an hour in a flask, and preserved in a tightly-corked bottle. For use, a few drops are filtered into a watch-glass, and the prepared cover-glass, inverted, is permitted to float on it for at least ten or fifteen minutes, after the solution has been previously warmed. The cover-glass is then well washed in water, dried between filter-paper and then over a spirit lamp, and finally mounted in Canada balsam. The red blood-cells are stained rose, the nuclei of the leucocytes a deep dark-blue, and any plasmodia in the blood are stained a delicate sky-blue.

The segmented bodies that exhibit ameboid movements were never absent in sucklings. Though sought for in other than malarial diseases, the plasmodia were never found.—*Wiener medicin. Presse*, No. 17, 1891.

LOCAL AND GENERAL ANESTHESIA.

Grandclément (*Lyon Médical*, No. 12, 1891) states that local anesthesia usually suffices for the performance of minor operations, such as the relief of ingrowing nails, opening of abscesses, enucleation of small, superficial tumors, or to overcome the circumscribed pain of inflammation or of neuralgia. Several methods have been proposed for the purpose, but all are not equally valuable or secure.

1. *Anesthesia by congelation with the aid of a refrigerant mixture of salt and ice* was the only method used twenty-five or thirty years ago; to-day it is almost abandoned. It is painful and time-consuming, and is best applicable to the extremities, the toes or fingers, which can be plunged into the mixture. Besides, ice cannot always and everywhere be obtained.

2. *Spraying with ether* originated with Richardson twenty-five years ago. It is superior to freezing with ice; it requires a special apparatus and protracted application, and is sometimes quite painful.

3. *Spraying with ethyl chloride* has recently been recommended. Ten grams of ethyl chloride contained in a small glass bulb, terminating in a capillary tube that has been sealed in the flame of a lamp, are vaporized by the heat of the hand (ethyl chloride vaporizes at +10° C. (50° F.). A fine spray escapes when the tube is broken. In a short time the area sprayed presents a white appearance and a degree of anesthesia sufficient to open deep abscesses and to perform other minor operations.

4. *Hypodermatic injections of cocaine* induce phenomena of profound intoxication in certain individuals, even when small doses are employed. Unpleasant symptoms sometimes follow the instillation of cocaine into the conjunctival sac. In the violent periorbital neuralgias that are provoked by certain affections of the eye, Grandclément has obtained good results from injections of cocaine and antipyrine in association. He believes that the edema and vascular stasis resulting from the injection prevent too rapid absorption of the cocaine. The same end is attained by applying an Esmarch bandage to the part before the injection of cocaine is made. Grandclément has observed that the anesthesia produced by the mixture of cocaine and antipyrine persists for several days.

MEDICAL PROGRESS.

Circular Enterorrhaphy.—Paul (*Liverpool Med.-Chir. Journ.*, July, 1891), in cases in which end-to-end apposition is indicated, employs a decalcified bone-tube from an inch to an inch and a half long, from one-half to three-fourths of an inch in diameter, and from one-sixteenth to one-eighth of an inch thick, the lower end of which is perforated for suturing the proximal end of the bowel to it. A double thread, carrying a needle, is fastened to the tube to facilitate invagination. The tube is entirely introduced into the proximal portion of the bowel, the free margin of which is sutured to the tube through the perforations by means of fine chromicized catgut. Care should be taken to include in the suture the severed edges of the mesentery. Next, the needle armed with the double thread is introduced on a director into the distal segment of bowel, and, at a distance of three inches, made to emerge through the wall of the intestine. Then the distal end is sutured all around to the proximal end through the muscular and serous coats by means of chromicized catgut, special attention being again given to the mesentery. An assistant now makes traction on the double thread and resists the operator as he draws the distal end of the bowel back over the tube, thus invaginating the proximal end. The parts are retained in position by a few Lembert sutures, one on either side of the mesentery, and others as needed. The double thread is finally drawn tight and cut off short.

Pathological Anatomy of Rheumatic Facial Palsy.—Minkowski (*Berliner klin. Wochenschr.*, July 6, 1891) reported the case of a laborer, twenty-seven years old, with paralysis of the muscles supplied by the terminal filaments of the left facial nerve, following exposure to a draught. Fluids dribbled from the corner of the mouth; there were pain in the ear and derangement of hearing; the tip of the tongue deviated slightly to the right side; there was paresis of the left half of the soft palate; the uvula deviated to the right; there was moderate tenderness in the right parotid region, but no other derangement of sensation. The sense of taste was impaired in the anterior portion of the left half of the tongue, with a sense of dryness in the left half of the mouth; there was epiphora on the left; acuteness of hearing was heightened on the left. Degenerative reactions in nerve and muscle had begun. A diagnosis of rheumatic palsy of the facial nerve was made. Under treatment some improvement took place. The patient, however, committed suicide by taking hydrochloric acid. The autopsy revealed advanced neuritic degeneration in the peripheral distribution of the nerve, from the geniculate ganglion downward, no evidences of an inflammatory process in the bony canal for the nerve or in the neurilemma being discovered.

Rheumatoid Arthritis.—Sir Dyce Duckworth (*Liverpool Med.-Chir. Journ.*, July, 1891) accepts a neuro-humoral pathology for most features of gout and gouty ailments, and by analogy for rheumatism. In both he finds a dominant nervous element. In rheumatoid arthritis, however, proof of any humoral element is wanting. The relation of this disorder to rheumatism and to gout is inconstant. Sir Dyce Duckworth maintains, with others, that the articular lesions are peripheral manifestations of a degenerative change in a hypothetical center for the joints, situated in the medulla. The view of the nervous origin of rheumatoid arthritis is borne out by the results of therapeutics—iron, cod-liver oil, arsenic and nutrients constituting the best means of treatment.

Interstitial Injections of Corrosive Sublimate in Carcinoma of the Breast.—Chéron (*Revue Médico-Chirurg. des Mal. des Femmes*, July, 1891) has reported three cases of advanced carcinoma of the breast, with involvement of the axillary glands, in which excellent results attended interstitial injections of corrosive sublimate. Fifteen minims of a 1 : 1000 solution were injected two or three times a day, with vigorous antiseptic precautions. The injections occasioned little pain; in no case did suppuration occur.

The Mortality Among Breast-fed Infants. — Sabatier (*Lyon Médical*, 1891, No. 24) has observed that the mortality of infants nursed by women who for one reason or another use but one breast for nursing is considerably higher than in infants nursed from both breasts. In thirty-two of the former, seen in public service, the infantile mortality was 48 per cent.; in the same number of the latter, under similar conditions, the mortality was but 28 per cent.

To Detect Tubercle Bacilli in Sputum.—Kroenig (*Berliner klin. Wochenschrift*, July 20, 1891) has recommended a modification of the method of Biedert, as a result of which the otherwise necessary delay of a day or two is obviated. The sputum, liquefied by the addition of a dilute solution of soda and boiling, is evaporated in a centrifugal apparatus. In the sediment that remains bacilli are more readily found than if the original bulk of the sputum were examined.

Miners' Nystagmus.—In a second communication upon the subject, Snell (*British Medical Journal*, July 11, 1891) presents some evidence demonstrating that the nystagmus seen in miners is not at all dependent upon the use of safety lamps, but that the derangement is only observed in those whose special work necessitates their assuming constrained positions, upon which it is shown the ocular oscillation is dependent.

Non-pathological Albuminuria.—Winternitz (*Zeitschr. f. physiolog. Chemie*, Bd. xv.) treated by evaporation and precipitation the urine obtained from a number of apparently healthy individuals, in which albumin could not be detected by the ordinary tests, and was unable to find albumin. As a result, he concludes that normal urine does not contain albumin.—(*Centralb. f. med. Wissensch.*, July 11, 1891).

Purulent Inflammation of the Thyroid Gland following Pneumonia.—Marchant (*Wiener med. Presse*, July 12, 1891), at the French Congress of Surgery, reported the case of a woman seventy-two years old, in which, three weeks after an attack of pneumonia, a purulent inflammation of the left lobe of the thyroid gland appeared. In the pus evacuated by incision, pneumonia cocci were exclusively found.

The Medical News.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to The Medical News will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment. When necessary to elucidate the text, illustrations will be provided without cost to the author.

Address the Editor: GEO. M. GOULD, M.D.,
1004 Walnut Street,
Philadelphia.

Subscription Price, Including Postage in North America.

Per Annum, in Advance . . . . . $4.00.
Single Copies . . . . . 10 cents.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
Nos. 706 & 708 Sansom Street,
Philadelphia.

SATURDAY, OCTOBER 24, 1891.

HUMAN LIFE UNDER DENIED SENSATION.

The writer once experienced an odd series of feelings that brought vividly to mind the fact that life and emotion and happiness are compatible with great differences in and deprivations of ordinary mental stimuli. A social gathering was going on in a large hall, and the sounds of excellent music, dancing, laughter, and gayety, came from this room where a hundred or more happy folk were passing happy hours. Upon opening the door and being ushered into the hall the room was found to be as dark as midnight. Not a thing could be seen. It was the social hour of the inmates of an institution for the blind! The first uncanny, creepy feeling was soon dissipated by the thought of congratulation that indomitable mind and spontaneous emotion, though deprived of light and vision, could still find satisfaction and play through the medium of indirect sensation. Soul still conquered sense!

The same thought is exemplified and emphasized by a consideration of the report of the Convention of Deaf-Mutes lately held in Allentown, Pa. One is apt thoughtlessly to pass over the beginning of the report, that says, "The meeting was called to order by the president, who rapped vigorously on the desk to attract the attention of his audience." An audience of deaf-mutes called to order by a noise! Those who see a blind man tapping the street in front of him as he walks are apt to think that this is solely to avoid objects that the cane may strike. It is also to avoid objects that the cane does not strike—because to the blind man's ears and hand there is a *timbre* from blows upon the pavement near its edge, near posts or steps, that is very different from the resonance when the blow is not near such objects. It is said that blinded bats are able to fly unharmed, avoiding objects in their flight by means of the perception of an increase of barometric pressure of the air close to those objects—so sensitive to variations of pressure is the expanded interdigital membrane. (The experimental blinding of the bat, however, was not necessary, because millions of bats winter in Mammoth Cave, miles from the faintest ray of light.)

A suggestion is indirectly aroused by this fact as to the "relaying," if one may so speak, of crude and faint stimulation by the mechanism of the nerve-ganglia and centers. There is a nervous device that reïnforces and transforms whilst also repeating the subtle, weak, and in themselves meaningless, hints of the external world that we call sense-impression. It is the living prototype of the electrician's "relay" and microphone combined. Thus all man's mechanic devices are but poor imitations and repetitions of what Life's vital forces have long ago brought to wondrous perfection!

In the deaf-mutes' convention prayer was said, the roll called, addresses made, business conducted, and long sessions held—all in the sign-language—all in silence! "The amended constitution and by-laws were adopted *after a lively debate.*" If present, our blind friends would certainly have thought the meeting very strange and stupid. But the success in raising funds for a proposed home for aged and infirm mutes, and the discussion of other worthy objects, made the gathering a very interesting one for the attending delegates.

According to the Paris correspondent of the London *Times* the method of analyzing motion by the chronophotograph, which has been so happily applied by M. Marey in the case of moving animals, such as horses running or birds and insects in flight, has recently been employed by M. G. Demeny, a preparator at the physiological station of M. Marey, to examine the movements of the lips in speaking. He has obtained results which show that the form of the mouth is quite different for the different articu-

late sounds. With these photographs combined in a zoetrope he has reproduced the movements of the lips by synthesis. An ordinary person finds it difficult to read the words by the animated pictures; but a deaf-mute who has been accustomed to read from the lips of a speaker, found it easy to do so from the photographs. A young pupil of the National Institute of Deaf-Mutes in France could read the vowels and diphthongs as well as the labials. The first experiments were, of course, not all that could be desired; but, in bringing the matter before the French Academy of Sciences, M. DEMENY expressed the hope that in continuing his researches he would be able to develop a new method of educating deaf-mutes by sight from more perfect photographic images. Obviously a magic-lantern lecture might be delivered to an audience of deaf-mutes in this way.

The encouraging and deeply suggestive fact of rescuing the faculty and power of speech in these deaf-mutes is one that must command the sympathy of all. There is no limit to the ingenuity of Life and to her triumphs over adverse circumstances and deprived stimuli. We have all read of another striking example—very different in kind, of course, but illustrating the same great truth. One of England's greatest statesmen was blind; so was a great numismatologist; and another of her great men, a hunter and rider of unexampled daring, a peerless sportsman, an excellent business man, and active administrator, had neither arms, hands, legs, nor feet. One is reminded of EMERSON'S cool answer to the Millerite who excitedly told him that the world was to come to an end that day: "Oh, well!" said the philosopher, "we can get on very well without it."

It would seem that if loss of sight were added to loss of hearing and speech, naught but tragedy and melancholy could be left, or that the routine life of the lowest functions of nutrition, etc., would persist. But there are few happier and brighter-minded people than LAURA BRIDGMAN was and than HELEN KELLER is. Another, a man likewise deprived of these great avenues of influence from and communication with the external world, without which life to us would seen so barren, travelled all over the United States alone, raised a family, and lived out his period of brave and satisfied life. He could talk with anybody by means of the ingenious device of tattooing the English alphabet upon different parts of his hand. Words and sentences were spelled out and recognized by the positions of the letters touched. The emotional life of these imprisoned souls, cut off from so many relations and avenues of interchange with the external world, must be all the more vivid and hypersensitive. A coarse jar of the hyperesthetic receiving end-organ of sense is transformed into a rude thunder by the highly attuned and delicately responsive microphone of the inner sensation-making mechanism. Thus the possibility of causing sharp sorrow is a necessary concomitant of the ease of eliciting joy. It is the glory of civilization to care for such and shield them from pain, and it is the delight of medicine to minister to them its healing. It is hard to sympathetically understand and realize the inner life of these almost windowless minds. How strange must seem to them the dreams and somnambulisms of never-to-be awakened emotions, the dumb reaching out toward reality of denied possibilities, the unsatisfied hungerings of imprisoned sensibilities. Their minds must be thrilled by dim hereditary echoes and the far-away caresses of ghostly ancestral hands. With what pathetic half-responsiveness do these shut-in souls catch the shimmer of long-departed life, that comes to them like the last faint evening flushings reflected from distant mountain-tops to valley-dwellers that are in the night.

A RATIONAL MEDICAL NOMENCLATURE.

THERE are too many proper names in medical nomenclature. The sooner a change is made, the better. In the selection of a name for an object, a condition, or a disease, descriptiveness should be aimed at. It may, however, be interposed that knowledge is at first crude and that names descriptive at one period of history may convey no adequate idea at a later period. While it must be admitted that this objection is supported by an element of truth, still in the selection of a name it were more logical to choose one that carries with it an idea than to designate a condition after its discoverer. If this conception were adhered to there would be fewer contests for priority of description.

No department of science is more ready than medicine to bestow appropriate credit upon its deserving members, but there are other ways of doing this than by obstructing the progress of knowledge by imposing upon laboring memory the additional burden of a mass of meaningless names. To see that honor and distinction are awarded to

those to whom it is properly due should be the duty of historical medicine.

As knowledge grows broader and more profound, the compound becomes resolved into its component elements. What at first appears simple is discovered to be complex. It is at this stage that we have arrived as regards so-called Bright's disease. While we do not know all there is to learn concerning the various morbid conditions of the kidney, it has long since been demonstrated that what was originally described as Bright's disease is not a single condition, but that Bright's disease represents a variety of different pathological lesions. It is on this line of thought that Delafield (*American Journal of the Medical Sciences*, October, 1891) at the recent Congress of American Physicians and Surgeons proposed to discard the designation Bright's disease as no longer serving a useful purpose. He divides the diseases of the kidney into congestion, inflammation, and degeneration. Each of these may be acute or chronic. Acute nephritis may be exudative, or productive, or diffuse; chronic nephritis may be productive or diffuse, with or without exudation, suppurative or tuberculous. The degenerations are all secondary. These designations are sufficiently expressive; they meet all the indications for the present; they are elastic and will permit of extension as occasion may warrant.

The medical profession will always hold in deepest reverence the memories of such men as Richard Bright, but let us make the nomenclature of medicine rational.

LOVERS OF HYPOCRISY.

There is one aspect of the tempest in a teapot that seems to have been aroused among the Hahnemannian knights by the criticisms of The News—one important aspect, that is deserving of passing notice. In planning the "boycott" those with any approximate sincerity of conviction should ask themselves if in the long run a hypocritical enemy is not more to be feared than a frank enemy. Is open-field or ambush fighting the most indicative of civilized warfare and honorable character? Do they imagine for one foolish instant that those "allopathic" journals and editors and publishers that are silent, evasive, compromising, or even flattering to them, have any opinion of their peculiar medical creed and practice essentially different from that frankly outspoken by The News? Do they imagine for one foolish instant that the silence, the evasion, the offers of compromise and flattery, represent anything but "policy" cloaking concealed contempt? An honest man prefers an honest enemy, but the subconsciousness of error makes one beg for dishonest friends. And the dishonest friend is always on the lookout for dupes.

SOCIETY PROCEEDINGS.

THE AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION.

First Annual Meeting, held at Philadelphia, September 24, 25, and 26, 1891.

(Continued from page 471)

First Day—September 24th. Evening Session.

Dr. Horatio R. Bigelow, of Philadelphia, read a paper entitled "Eight Months' Work at the Free Dispensary for Women," in which he said that for purposes of observation and study, individual clinics were a necessity, to afford a wider range of observation and a larger opportunity of weighing evidence than can be obtained by a fluctuating private practice. Refinement, scrupulous care, and precision, are requisite in formulating a diagnosis.

At the dispensary, 75 new cases had been treated, between 600 and 700 applications having been made. Fifty-eight punctures were made in 15 cases of uterine fibroids. Three tumors were subperitoneal, the others mural. The mean current-strength used for vaginal applications was 35 m.; for punctures, 85 m. In simple cases of salpingitis and salpingo-ovaritis, symptoms are relieved by vaginal applications, but cures are never accomplished. In simple, uncomplicated cases, in which the tubes are not constricted, and when the dribbling into the uterus has not been interfered with, intra-uterine applications, supplementing the vaginal, do have a marked influence for good. The cases of large tortuous tubes, with thin and distended walls, irregular swellings, denoting pus-pockets and pronounced cachexia, demand surgical interference. Electricity can do no possible good—it may do much harm. Hence one object of a well-conducted clinic is differentiation—to know what cases to treat, to realize that there is such a thing as over-treatment, and that electricity is not a panacea for all female pelvic disorders. Some other things are learned. Many tumors appear benefited symptomatically only. Soft myomata, fibromata undergoing degeneration, and subperitoneal tumors, are not, as a rule, benefited anatomically. In one case, a large subperitoneal fibroid has been punctured a dozen times through the vagina, without apparent diminution of the growth, and without decided change of symptoms. Locomotion is difficult and painful. This was an unfortunate test-case, because subperitoneal growths, being far out of reach, resist the action of the current, and because the patient's surroundings are most lamentable. She is a type of poverty. She lives in filth, is insufficiently nourished, and drinks to excess. Confidence in any therapeutic measure should not weaken one's honesty in the recapitulation of results. In this case electrolytic punctures have been tried with three needles through the abdominal parietes, without

apparent diminution of the growth of the tumor. It has changed its form from a prominent dome-like swelling to a broad, lobulated lateral mass, somewhat lower down in the pelvis. While abdominal puncture might, theoretically, be proper, the results of operation are against its use. When the abdominal walls are thin and transparent, when the intestines do not overlie the tumors, and the bladder is at a safe distance, abdominal puncture may be considered.

All the cases of fibroid treated were made comfortable. No tumors have disappeared; two are reduced in size. Under better hygienic conditions and regular treatment better results can be obtained than is possible in a clinic. Many cases come irregularly for treatment, and are not under constant observation, and all are badly nourished and improperly cared for. Small intra-mural tumors, hard, and not very painful, that are taken in hand as soon as noticed, always do well under the buried negative puncture, and are made to disappear. Inflammation of the adnexæ, old chronic salpingo-ovaritis, demand the greatest possible care and dexterity in their management.

Of the first importance is accurate diagnosis. It is a *sine qua non* of success that the electro-therapeutist be a thoroughly competent gynecologist, if he intend limiting his practice to the diseases of women. This end can only be attained after years of work with ample material, and it would be well for the science and art of medicine if a more enlightened view of pathology should be conjoined to it. The clinician should know all about the processes that give rise to abnormal conditions, that he may have a clear conception of the limits and degree of acute inflammations, and of the nature and extent of degenerations. Otherwise he gropes in the dark, and his labors will be in vain. Pathology is far too commonly neglected. In acute disease of the adnexæ, the introduction of a sound unless in competent hands is apt to create mischief. Not only is the lining membrane of the tubes in a hyperemic and hyperesthetic condition, but the whole endometrium also, and it is bad practice to resort to any measure that will intensify such pathological processes. The same conditions exist in some chronic states. Cases in which active inflammation of the peritoneum has been reported after application of the intra-uterine current have probably been so caused. In such cases treatment may be begun with vaginal applications of great delicacy, until the patient's uterus becomes tolerant of a foreign body; in all cases of extremely tortuous or constricted tubes, interference should be refrained from. Dr. Bigelow expressed firm faith in the value of electricity in gynecology, but he realized that incompetence, immoderate enthusiasm, and faulty differentiation are to be avoided. Electricity is employed in the treatment of the diseases of women by those who have not the requisite experience or the modesty for its successful employment. Faulty complications do not happen to competent electro-gynecologists.

Any inflammatory process in the pelvis will be followed by some effused lymph, which may form adhesions. Most tumors are complicated by adhesions. An objection to electro-therapeutics based on this ground would not hold. The work of abdominal surgeons must not be judged from imperfect and inadequate data. Many tubes and ovaries are removed without sufficient cause, but these instances are not often from the record-book of competent abdominal surgeons, but are usually the belongings of a young ambition, anxious to climb. Surgery is handicapped with incompetent practitioners just as electro-therapeutics is, and it is not one bit more logical to lay all miserable failures and mistakes at the door of honest surgery, than it would be for surgeons to conjure all sorts and conditions of doubts, and to hold the responsible intelligences among electro-therapeutists responsible for engendering them. It must be remembered that eminent surgeons see a class of cases in large numbers that rarely, if ever, come to smaller clinics—cases in which nothing but operative interference could be of the least service. So it is not to be wondered that surgeons arise in their wrath when lesser lights, who know little or nothing of such aggravated forms of disease, dispute the necessity of operating. In some cases neither electricity nor expectancy can accomplish aught; in others, the employment of electricity would be most pernicious; and there are now and always will be cases that will not be benefited by electricity. One of the greatest dangers is the over-claiming of young and restless men, and the unequivocal condemnation of honest intelligent surgery by those that know little of either abdominal surgery or electro-therapeutics. Personalities are offensive, and are not arguments. Honest surgeons do not rail at intelligent electro-therapeutists, but they do object to inexperienced gynecologists and unlettered electro-therapeutists claiming marvels for a method of which they can know little or nothing—and they have a right to object to the criticism of men that know nothing of pathology. The tone of recent discussions in special societies is to be deprecated. Surgeons must not impugn the motives of earnest electro-therapeutists. A study of electricity is fraught with difficulty, and is not to be had for the asking; there are very few operating surgeons who know anything about it. Therefore they are not competent witnesses.

Dr. Walling, of Philadelphia, having seen many of the cases alluded to, stated that nearly all of the cases of fibroma were in persons who had been poorly nourished. If such cases were properly nourished, if they could be placed in a hospital on a nourishing diet, they would be in much better condition for treatment, with prospects of partial or complete recovery. The trouble seems to be a lack of nutrition. If Nature does not have the proper supply of nutritive elements, she must build of what she does get, so that a lower grade of nutrition results.

Dr. Hayd stated that he had no doubt but there is some harm done by the use of electricity, but not more than there is by the use of other powerful remedies, such as strychnine, morphine, and similar drugs.

The young man just from college, with no special training in gynecology, should be cautioned that he has a powerful agent when he uses electricity, and that he may do a great deal of harm if the agent is not properly employed and a great deal of good if it is properly employed; he should be enjoined to make as few intra-uterine applications as possible. Years ago, when the sound was introduced without proper consideration, its influence was almost as baneful as is that of electricity to-day in the hands of unscientific men.

If there is an acute or a subacute condition, and the

electrode is not introduced with the greatest care and the greatest cleanliness has not been exercised, an inflammation may be lighted up, with all its attendant dangers.

In reply to an inquiry, Dr. Bigelow stated that he had treated two cases of malignant disease of the uterine adnexa. In one electricity did no good, but rather aggravated the condition; in the other, in which the malignant disease was confined to the cervix, the results were brilliant. If the recent knowledge of the pathology of carcinoma is correct—that is, that it is simply a normal cell exaggerated in growth and not a distinct cell, but simply a normal growth with a normal composition, displacing the normal cells, with subsequent degeneration—then the galvanic current should be of great use. Malignant growths of the adnexæ are not benefited in the least by galvanism, but are rather aggravated.

Dr. Massey referred to a case in which a large sarcoma of the adnexa was greatly helped by electricity, being much retarded in growth, although not cured.

Dr. Robert Newman, of New York, read a paper on "Electricity in Carcinoma," in which he presented the various modes in which electricity has been used in the treatment of carcinoma, and showed that undoubted cures had been reported. Four different methods have been used: First, Galvanism; second, Electrolysis; third, Galvano-cautery; fourth, a combination of two of the preceding.

Galvanism has been applied externally with pads or sponge electrodes and (the interrupted current) with needles. The external application by the galvanic (constant) current with two sponge electrodes to the skin on or near the tumor has not met with success; it seems only to have stimulated the carcinomatous cells to greater proliferation, and thereby hastened the fatal termination.

In the treatment of carcinoma by electricity *electrolysis* has been mostly used, and is best known. It differs widely from the first method of galvanism, which is expected to destroy the carcinoma by a strong mechanical action. Electrolysis, on the other hand, either destroys, causing decomposition by its chemical action, or causes absorption, according to the strength of the current employed. The art of applying electrolysis successfully consists in using the correct strength of electric current, applying the respective poles in the right place, selecting the size, shape, and material of the electrode, and regulating the duration and intervals of séances. A mild current can effect absorption only—a strength of from 5 to 30 milliampères, and even more, may be used, according to the requirements of the case. A strong current of from 25 to even 200 milliampères (and some operators have used even more) will destroy tissues to such a degree that the tumor may slough off as a dead mass. A good rule is to apply the current not stronger than necessary to accomplish the desired object.

It is not yet decided whether or not there is an interpolar electrolysis. It is only certain that the decomposition by electrolysis is greatest at and around the terminus of the poles. From experiments made by Dr. Newman it seems that the electrolytic action extends around the needle in a radius of from one and a quarter to one and a half inches. Concluding that electrolysis is capable of destroying carcinomatous cells, and that it causes specific decomposition at the pole and within a radius of one and a half inches, if needles are inserted in a tumor at a distance of two and a half inches it may be expected that the electrolytic action will affect the interval between the needles and destroy the integrity of the carcinomatous cells. Dr. Newman has, therefore, operated principally by two methods. If absorption by electrolysis was intended, the whole tumor was electrolyzed in sections with needles connected with the negative pole—one, two, or more needles being introduced into the tumor at a time—while the positive pole was applied as a large pad outside on the cuticle or near the tumor. Weak currents are employed. An anesthetic is not required. In the second method both poles are represented by needles. The positive pole (a single needle) is placed in the center of the tumor, the negative needle or needles at the circumference of the tumor or even beyond, but near the margin of the tumor. Destruction and sloughing of the diseased mass takes place.

Dr. Newman began the electrolytic treatment of carcinoma in 1874, and has since had considerable experience. The results varied: some were failures; in some cases the patient's life was prolonged; there were also cures, some patients remaining well without any sign of recurrence of the growth for many years.

The treatment of carcinoma with the *galvano-cautery* has been practised by many, but it seems that Dr. J. Byrne, of Brooklyn, has had the greatest experience and success. Of 367 cases so treated, there was no return of the disease in from two to eight years in 153 cases.

Finally, electricity may be employed in the treatment of carcinoma by a combination of any two of the methods already considered. Most commonly the applications of the electrolytic and of the galvano-caustic effect of the battery are combined in the same case.

How is electricity expected to cure carcinoma? 1. Strong currents of galvanism are expected to destroy the carcinomatous cells by a mechanical action. 2. A removal of carcinomatous tumors by extirpation (amputation) is effected by the galvano-cautery. 3. Electrolysis with a mild current facilitates absorption by inducing chemical decomposition. 4. Electrolysis with strong currents acts by its destructive influence. Whichever method is used, it must be applied thoroughly and systematically, removing all the carcinomatous cells. Success can only be expected in the earlier stages of the disease, when the malady is local and the malignant mass is concentrated in one small tumor. If the carcinomatous cells are distributed in different parts of the body, and the disease has advanced far, success cannot be expected.

The treatment of carcinoma by means of electricity possesses advantages over other methods. 1. The facility with which electricity is applied; some methods can be carried out without an assistant and without an anesthetic. 2. The operations are free from danger. 3. There is no shock after the operation. 4. It is easier to get at the entire disease in an early stage than by any other means. 5. It can be used in places anatomically dangerous and beyond the reach of the knife, and the horror of the knife is avoided. 6. It retards the growth, prolongs life, and benefits the

patient, even if it does not always cure. 7. The patient is not necessarily confined to bed or house. 8. The operation does not cause pyemia or septicemia. 9. There is no danger of hemorrhage, but hemorrhage is controlled. 10. There is more chance of a cure and better healing after the operation. 11. It always allays pain.

Dr. Hutchinson related that he had operated on sixteen cases, of which two are still living. One was a case of epithelioma of the lower lip removed fourteen years ago. There has been no return and the patient is in good health. The other was in a woman from whom a breast and the two labia majora were removed; after twelve years she is in good health.

Dr. Hutchinson was firm in the belief that carcinoma is curable by galvanism.

Dr. Massey stated that he had used a method different from any mentioned. It consisted in the application of the carbon positive pole of a strong current directly to a limited surface of the diseased tissue. In that way, the parts being free from excessive sensation, the ready destruction of the carcinomatous tissue is accomplished, with immediate cessation of the bleeding that annoys the patient. Dr. Massey had in one application, with less than one hundred milliampères, arrested a hemorrhage that had lasted a year, and the hemorrhages have not recurred. The carcinomatous tissue subsequently comes away under the influence of antiseptic douches in white crumbs, and leaves a clear, hard excavation.

Dr. William F. Hutchinson, of Providence, read a paper entitled, "What a General Practitioner Can Do with Electricity," in which he cautioned against prettily finished boxes, the contents of which are sealed, upon which repairs can only be made by the maker. He advised that no form of galvanic cell be bought unless every part may be easily inspected, readily understood, and quickly reparable without expert aid. He believed that some form of Grenet cell is the best that a general practioner can find for portable use. For office work, where great life with small trouble is required, he has not found anything to equal the new Edison cell, catalogued as "Type C." It will give exactly the same voltage—about seven-tenths volt per cell—during its entire life, about a year of ordinary service.

For faradic machines, he recommended a Du Bois-Reymond coil with two Grenet cells in the box. One of these will be sufficient for ordinary use, but in asphyxia from gas-inhalation, in drowning cases, and especially in opium-narcosis, when it may be necessary to prolong the treatment for hours, a second cell is called for. Perhaps the best faradic machines in America are made by Fleming, of Philadelphia.

Among the diseases that Dr. Hutchinson thinks may be successfully treated by the general practitioner are functional derangements of special sense, and such forms of their paralysis as are dependent upon excentric causes; certain forms of dyspepsia dependent upon atony of the stomach-nerves: sexual neurasthenia and impotence springing thereform; peripheral neuralgias and such other neuralgias as are confined to long nerve-trunks; herpes zoster; muscular rheumatism; neuralgic dysmenorrhea, and parametritis.

Dr. M. J. Grier, of Philadelphia, read a paper on "The Treatment of Some Forms of Sexual Debility by Electricity," in which he said that of the incidental inquiries presented to the physician, many of them will refer to the derangements of the sexual functions. The individuals usually seek relief from a neuralgia, pain in the back, muscular debility, or some other cause leading easily and naturally from the ostensible to the real object of the visit. This is generally the case with the younger subjects who have become conscious of an appreciable physical failure, or who, from the presence of some slight subjective symptoms, are apprehensive that such failure will certainly occur. Another class will seek relief from conditions fully developed and are at once freely communicative. Both classes have morbid ideas as well as erroneous opinions concerning their condition, which add difficulty to their management. Some of them have already been under treatment; the family physician has been consulted, and iron, strychnine, and electricity have been continuously administered, but without the desired result. The larger number of such cases present a state of local and general debility resulting from excessive and long-continued stimulation of special nerve-endings, with consequent exhaustion of the spinal and cerebral centers controlling the parts involved.

The neurasthenic condition of the patient will probably and justly demand the earliest attention. Whether it be the cause or the effect of the sexual debility, the progress and results of the local treatment will be much more decided as this state disappears. In one class, and a large one, there will be found to be a lowered functional activity of the entire nervous system, depending on preceding mental depression caused by the gradually developing consciousness of the diminution of the virile power and the fear of its complete abolition. In another class, of more mature years, there are varying degress of debility, ranging from actual impairment of function to complete loss of power.

In addition to the value of properly directed medication, aided materially by the change in the morale of the patient, as the physician succeeds in inspiring him with the hope of relief by demonstrating to him its possibility by the results of treatment, electricity is a potent factor in his restoration. Independently of the special character of the neurasthenia, beyond the recognition of the sexual disturbances, galvanism to the head and spine may be at once employed. Central galvanization, with its catalytic and alterative effects, will perhaps best meet the indications; the method may be varied to suit each particular case, but, as a rule, the effort will be to bring the central and spinal centers under its special influence by either increasing or diminishing their irritability. In the application to the head, the vertex is well moistened and a two-inch electrode firmly applied. The vertex is selected because the current is well borne at that point, there is less vertigo or other apparent cerebral disturbance. To diminish cerebral irritability the positive pole should be applied, as its effect appears to be the more sedative. The negative electrode is a slightly convex button, two inches in diameter.

Pure tin plates of about No. 28 gauge are preferable for electrodes, as they are soft and are easily moulded to any curved surface and are always bright and fresh-looking; these are covered with ordinary muslin, such as cotton shirting. Perhaps equally important is the greater uniformity in the relation of the electrode to the

skin, as to distance; it never varies $\frac{1}{100}$ of an inch, keeping the current-intensity quite regular; while with the sponge the ever-varying distance and pressure may be quite enough to convert an intended stabile into a labile application. Having adjusted the positive plate to the vertex, the negative is placed subaurally on either side; beginning with a minimum amount of current, say about two milliampères, and a uniform pressure, the negative electrode is slowly moved down over the region of the cervical sympathetic nerves until the first dorsal vertebra is reached, when the current-strength may be gradually raised to five milliampères; the electrode is then passed slowly down on each side of the upper spine. This current-strength should be maintained, as the increased resistance of more tissue is brought into the circuit. As a rule, the electrode need not pass below the dorsal vertebræ, depending on the kathelectrotonic state induced below that point, and reserving the special lumbar and sacral centers for subsequent treatment. Carefully avoiding any abrupt change of application and pressure, the positive may now be placed over the inferior cervical ganglion on either side and the negative traced over the course of each dorsal nerve, thus gently influencing the sympathetic ganglia.

It is probable that in a labile application of the current, the movement of the kathode over the tissues is equivalent to an opening and closing of the circuit, as each cell is successively subjected to its influence, and thus there is induced a momentary contraction or tonic state of the vascular muscles, resulting in improvement of circulation and nutrition. Perhaps, also, the electrical actions upon trophic-nerve tissues may produce changes in other tissues and organs of the body, organic metamorphoses, modifications of nutrition, which constitute a part of the "catalytic effects."

After a number of applications the general result of the treatment is apparent in the disappearance of the sallowness and nervous depression, and in a better cutaneous circulation, as shown by the improvement in the complexion, and in more refreshing sleep; there is also an improvent in the digestive functions, and a general feeling of buoyancy. In this way is afforded a better foundation on which to institute treatment of the local disturbances.

The loss of the erectile power is the most prominent of the local symptoms and is that which naturally impresses the patient most forcibly, and more than any other impels him to seek professional aid; to him it is but a single fact; to his physician it is evidence of the derangement of a complicated system of parts and functions, both local and general.

Such cases are found associated with long-continued continence and in men of excessive mental application, in whom the cerebral activity has been expended in other directions; also in those who have become sexually morbid, having lost the normal physical reflexes through exhaustion. They usually retain the physical reflexes and respond to stimulation of the local sensory nerves, thus proving that the spinal paths of the afferent nerves have not been impaired, or at least not to a very great extent.

In such cases the indications are to stimulate the nervi erigentes and the upper centers acting in conjunction with them. An ascending galvanic current of about five milliampères may be passed from the perineum, from over the third and fourth sacral nerves, where the vaso-dilator branches arise, and from the genito-spinal center of Budge, at the fourth lumbar vertebra, successively; the negative electrode should be carefully applied to the back and sides of the neck and to the vertex, in an endeavor to increase the excitability of the cortex in those in whom it is depressed, and to quicken the responses of the lower spinal centers to their impress.

Under ordinary conditions the vasomotor nerves are in a state of moderate excitation. If, from irritation of the vasomotor centers, the vasomotors are over-excited, and a controlling influence is exercised over the vessels supplying the erectile tissues, through their dominant control over the vaso-dilators, the engorgement of the sinuses of the cavernous bodies will be prevented and erection will be impossible. Such a condition is present as a result of excessive sexual stimulation, and is most probably dependent upon the irritation that precedes exhaustion of the centers. The excessive tone is shown in the diminished blood-supply to and the lowered temperature of the pale and shrunken organ. In persistent overaction of these nerves, the lessened blood-supply to the secretory organs is shown by the diminished quantity of their secretions and the consequent loss of this source of stimulation. In such cases, galvanism applied to the vertex and upper spine, as in neurasthenia, will diminish the upper central irritability, and good results will follow stabile applications to the lumbar region with a current of five or six milliampères through a positive four by four inch place, one of equal size being placed at some indifferent point on the lower portion of the thigh. The best results are produced by placing a moistened electrode about one and one-fourth inches square against the perineum—this should be the positive pole; the negative may be a plate of three inches square, applied continuously to the sacro-lumbar junction; the cords should be connected with the terminals of the primary coil. The application is begun with the minimum strength, which is gradually increased as much as the patient can comfortably bear, and is maintained for from ten to fifteen minutes. In some cases, usually in those who are less nervous and irritable, the effects are noticed at the time of the application; others may not notice a change for half an hour or longer after the treatment. In those in whom the sensory nerves are not very much impaired, the first impression may be a sense of tingling along the dorsal nerve of the penis, or it may be distributed over the inner surfaces of the thighs, through branches of the internal cutaneous nerves, often reaching to the knees. In a little time a warm, glowing sensation will be felt, mostly in the sacro-lumbar and gluteal regions; this being obtained, the application should cease. This effect may last for from a few minutes to several hours, and will be alluded to by the patient at a subsequent visit as causing a feeling of comfort and pleasure. The ultimate result is a restoration of the normal circulation and an improvement in the nutrition of the parts, with increased local muscular power.

The opposite condition of vasomotor relaxation is frequently encountered—an exhaustion following the state of irritability just described. When affecting the

centers controlling the genital organs, the result will be a passive engorgement with a flaccid elongation; the temperature may be normal or lowered, depending on the sluggishness of circulation; the muscles are undernourished and voluntary control of them is lessened; in many cases the secretion of the coronal glands is unpleasantly augmented. In the erectile effort, the vasodilators may be sufficiently active to enlarge the cavernous sinuses and increase the flow of blood thereto; but the weakened muscles fail to sufficiently retard the return of blood from them, and the result is a moderate increase of bulk, with a soft glans and an easily compressible body. As the nerves cannot be influenced by direct contact, the application of galvanism to those parts which anatomy and experience teach us are the most available, and through which reflex effects can be obtained, must be depended upon. An efficient method consists in the introduction within the urethra of an uninsulated metallic sound connected with the negative pole; the current of galvanism should not be over two or three milliampères, and should be slowly broken, say about twice each second, for not over two minutes; the contact should last only during the instant of making, occasioning a short interval of excitation and a longer one of rest. The improvement from repeated applications will be shown by the retraction of the organ to a normal size. The immediate effect of the application is due both to muscular stimulation and increased arterial contraction, but mostly to the latter. Two other methods may be employed to produce this stimulation. In one, galvanism is applied to the surface of the inner side of the upper third of each thigh, with a bare negative electrode, kept slowly moving, and using a current-strength only sufficient to develop a pungent irritation of the sensory nerves; to use more would be to overtax and exhaust the vasomotor nerves still further. The bare negative electrode of the inductive coil may also be used over the same region and for the same purpose. The vibrations should be slow enough to give perceptibly distinct shocks. In therapeutic applications the positive pole may be placed at any indifferent part, since the effect desired is the reflex action produced by the irritation of the negative pole.

Dilatation and turgescence of the sinuses of the corpora having occurred, it can be readily seen how a partial or complete failure of these muscles to act will impair or prevent erection. In their sexual activity, these muscles, while partly under volitional control, are mainly excited by reflexes, and in health very readily become equally active under the reflexes resulting from stimulation of the sensory nerves of the penis and adjacent parts. These muscles respond to the faradic and galvanic currents, according to their degree of health or exhaustion, and tests thus made may assist in the diagnosis of their condition. A suitable electrode, insulated where it comes in contact with the anal margin, may be introduced in the rectum and pressed against the anterior wall; a small, flat electrode, connected with the negative pole of the extra current should be applied to the perineum, and the current gradually increased in strength until muscular action is produced, which in health is quite strong. If the muscles fail to respond, or respond but feebly, the galvanic current may be substituted, maintaining the same polarity, making slow interruptions, with a feeble current, gradually increasing both the strength of current and rapidity of interruption. This proceeding answers very well for the direct treatment of these muscles. Decided contractions of the accelerator and compressor urethræ muscles may be obtained by substituting for the perineal electrode an uninsulated metallic urethral sound and using an uninterrupted galvanic current.

These muscles being supplied by the muscular branches of the pudic nerve, they may be indirectly stimulated by placing a positive plate-electrode over the sacrum, the rectal electrode becoming the negative and remaining as before; using, if the muscles are very feeble, a short constant current of not over two milliampères, supplemented by twenty or thirty interruptions, occupying about one minute. A weak muscle of this class requires a longer duration of current-action and short intervals of rest, if the current be of not more than the strength stated; vigorous treatment only seems to exhaust the already enfeebled parts. The rectal electrode may now be changed for a small perineal plate, and stimulation of the perineum and root of the penis may be made with a bearable strength of the extra current, slowly interrupted. This will produce both muscular and reflex effects.

Conjoined with defective muscular action, there is usually a lowered sensibility of the genital cutaneous and special sensory nerves, caused by the exhaustion following excessive stimulation. This will be found most marked about the prepuce and the glans, more particularly around the corona and the papilla beneath the meatus; also, if the anesthesia be profound, in the frænum præputialis. The cremaster reflex is sometimes diminished and may be abolished. Such cases may have a decided cerebral sexual activity with physical failure; or there may be a moderate erectile power, with loss of sexual pleasure and a retarded or incomplete orgasm. Sensibility of the surface may appear quite decided under electric tests, and the tactile sensibility be much enfeebled or lost, lessening the value of electro-diagnosis, excepting as to the condition of the muscles. As the local nutrition is usually impaired, resulting in relaxation of tissue and lowered temperature, both indications are met by the use of the galvanic current applied to the sensory parts most affected, by means of a small bare electrode, placing a medium-sized positive plate over the sacrum to include the origin of the pudic nerve, from which is given off the dorsal nerve of the penis. In treating the lowered sensibility of such nerves, the best results are obtained from a very mild current in this manner, and continued only long enough to produce a blush and a slight pungent sensation at the negative pole.

In the earlier changes of nerve excitability, one often finds an extremely sensitive condition, a hyperesthesia, in which even contact of the ordinary clothing with the surfaces will suffice to produce erotic excitement; preputial and rectal irritation, as well as other local causes, may also originate it. In many cases such irritation leads to direct stimulation of the genitals by touch, which, continued to excess, is a potent factor in producing abnormal excitability and consequent exhaustion of these nerve-centers. It is also a frequent cause of premature emission. Having removed or corrected the exciting

local causes, galvanism will aid in removing the central irritability. For its sedative action the anode is applied over the sacrum, a stabile current of not over five milliampères being used; the negative pole should be placed over some indifferent point, preferably to the lower limbs. It is essential to have a very mild current, free from any variation of strength, and to maintain the sacral pole evenly at one position and for a longer time than has been advised in other applications. Having thus treated the centers, the excitability of the nerve-terminals may be diminished by enveloping the penis in a soft metallic plate, thinly lined with moist absorbent cotton, to fill up irregularities and to make more uniform contact. This plate should be the anode; the kathode may rest on the abdomen. A mild, steady current through a sensory nerve for ten or fifteen minutes, traversing it in the normal nerve-current direction, will lower the excitability of the nerve. Urethral irritability is a most frequent cause of morbid action of the genital centers, and gives rise to various degrees of nerve irritation or sedation. Premature and painful emission may also be traced to congestion and irritation of the verumontanum. Similar impairment of functional activity may result reflexly from continued irritability of the mucous membrane of the urethra and ejaculatory ducts. An anodal application of a bare metallic sound, with a current of not more than one milliampère, and a kathodal plate over the lumbar vertebræ, will diminish the excessive irritability of this membrane.

(*To be continued.*)

CORRESPONDENCE.

CHICAGO.

The Provident Hospital and Training-school—What Constitutes Unprofessional or Dishonorable Conduct?—The Insane of Iowa.

The Provident Hospital and Training-school, the new institution which was founded here January 23, 1891, and dedicated to the public use May 4th, is in a flourishing condition. More than one hundred patients have been treated since the hospital was opened, and a number of nurses are being instructed in the best methods of caring for the sick and injured.

The organization of the hospital was due to the necessity of increased hospital facilities, and the undertaking has been successfully carried out. Indeed, the authorities of the institution are already talking of enlarging their quarters by securing the nine-room building in the rear of the hospital and turning it into a training-school for the nurses. This will doubtless be done as soon as sufficient funds can be collected, for the hospital relies for its support on the philanthropical. It treats patients who are unable to pay free of charge; those who can afford to do so make some return to the institution.

The medical staff is composed of Drs. R. N. Isham, and D. H. Williams, surgeons; Drs. Frank Billings, and Stanley M. Black, physicians; Drs. Henry T. Byford and A. A. Wesley, gynecologists; Dr. W. W. Jaggard, obstetrician; Dr. Horace M. Starkey, oculist and aurist.

The Secretaries of the State Board of Health of Nebraska have written to Attorney-General Hastings, asking what constitutes unprofessional or dishonorable conduct such as would authorize the Board of Secretaries to refuse to issue a certificate to a person applying therefor. The Attorney-General in his reply says:

"Section 14 of chapter 35 of the session laws of 1891, page 285, provides as follows: 'The board may refuse certificates to persons guilty of unprofessional or dishonorable conduct, and it may revoke certificates for like cause: Provided, always, that it has given the person an opportunity to be heard in his or her defence.'

"What is unprofessional or dishonorable conduct on the part of a practitioner of medicine is a question in which the courts appear to be wide apart. The section above quoted is a copy of the Illinois and Minnesota law upon the same subject. The code of ethics as laid down by medical associations furnishes us but little guidance concerning this question.

"To a greater or less degree each case of unprofessional or dishonorable conduct must be addressed to the sound judgment of the Board. No two cases will be quite similar in character. I therefore conclude that the Legislature meant by unprofessional or dishonorable conduct such conduct as was dishonorable and calculated to mislead or deceive—such practice, in short, as should not be indulged in by honorable men of any profession or calling."

Some of the figures from the recent report of the committee to visit the insane asylums of Iowa were recently published. Although there are three State insane asylums, located at Independence, Mount Pleasant, and Clarinda, beside the insane being cared for at nearly all the county poor-farms, the committee finds that insanity is on the increase to such an extent that it will be necessary, in order to properly look after the patients, to have another State institution, and recommends that such be erected.

PROGRESS IN THE MEDICAL COLLEGE OF THE STATE OF SOUTH CAROLINA.

To the Editor of The Medical News,

Sir: As an item of medical news that will be of interest to many of the readers of your journal, allow me to mention the great improvements now being made in the facilities for teaching in the Medical College of the State of South Carolina. Prominent among the colleges of ante-bellum times, she graduated many men of distinction, but the impoverishment of the South resulting from the war depressed the College for many years, and it was only through the devotion of her professors, who gave both time and talent without charge, that her doors were kept open to the youth of our own and adjoining States. As a matter of fact, however, despite these discouraging incidents, and, also, notwithstanding a want of coöperation on the part of many of her sister colleges, this school has consistently and persistently striven for a higher standard of medical education.

At the opening of the post-session it was determined to no longer wait for organized movement, but to at once take the initiative in this important matter and demand of matriculants three full sessions, with graded courses of instruction. Consequent upon this increased time for study came the demand for increased facilities, and this has been met by the addition to the College of

a large annex, in which are located a most perfectly equipped chemical laboratory, and model bacteriological and pathological departments, thoroughly fitted out by the "Alumni Association of the Medical College of the State of South Carolina," wherein students will find every facility for acquiring an intimate knowledge of these important branches. The best instruments and accessories of German manufacture have been adopted. Thus has this honored old school accomplished her cherished desire, and feels that she is second to none other in those facilities that go so far to graduate accomplished physicians.

Her faculty feels justly gratified at the promising outlook for the future of her usefulness, and is sure that this will give pleasure to all her friends.

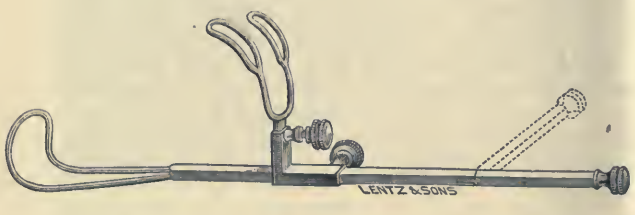
Very sincerely yours,

"MEDICUS."

CORRECTED ILLUSTRATION OF WEAGLY'S SELF-RETAINING PALATE RETRACTOR.

To the Editor of THE MEDICAL NEWS,

SIR: I enclose a corrected illustration of my retractor, in order that your readers may have a proper idea of the device. It will be remembered that no proof of the former illustration in THE MEDICAL NEWS of September 5, 1891, was sent to me by my instrument-maker, and hence the error. I would add that it is important to have the clamps or loops constructed of very light flexible wire, in order to permit of any desired change in curvature. The accompanying illustration gives a false idea that the material used in the nasal attachment is too heavy. Regretting the trouble caused you, I am, sir, etc.,



T. H. WEAGLY.

MARION, PA.

A CORRECTION.[1]

To the Editor of THE MEDICAL NEWS,

SIR: Will you allow me to correct a report of my remarks on the paper of Dr. Rockwell concerning electricity in extra-uterine pregnancy? Whlle I believe that faradism will "destroy the integument," I did not say so. I said that it would destroy the *embryo*. Medical faradic coils as ordinarily constructed will not destroy the skin, but currents from dynamos will. My belief as to the utility of faradism is based not alone on the results of treatment in the instances named, but on experiment with the products of conception obtained in cases of abortion in the specimens which have occurred in my own practice and in those sent me by friends. Microscopic examination in these instances shows that the mass is so disrupted by powerful faradic currents as to undoubtedly prevent further growth. The embryo thus treated is pulpified, so to speak.

The remarks of Dr. Morton appear to be incorrectly reported also. I do not think that he believes the primary faradic current to be "alternating;" it is direct and interrupted. The secondary, as found in ordinary medical coils is alternating, but it may be made direct (though interrupted) by "zig-zags" or commutators.

Sincerely yours,

WM. R. D. BLACKWOOD.

246 NORTH TWENTIETH STREET,
PHILADELPHIA, October 17, 1891.

[1] To avoid misunderstanding we would say that the Report of the American Electro-therapeutic Association as published by THE NEWS is furnished by the official stenographer of the Association.—*Editor of* THE NEWS.

REVIEW.

SURGICAL BACTERIOLOGY. By N. SENN, M.D., Ph.D., Professor of Surgery in Rush Medical College, Chicago, and in the Chicago Polyclinic; Attending Surgeon to the Milwaukee Hospital; Consulting Surgeon to the Milwaukee County Hospital and to the Milwaukee County Insane Asylum, etc. Second edition, thoroughly revised. Pp. 271, with thirteen plates. Philadelphia: Lea Brothers & Co., 1891.

THIS volume is rich in material valuable to the surgeon. The advance in surgical bacteriology has been so rapid that nothing written on the subject is likely to have value unless it is recent. For this reason the material for this work has been largely obtained from current literature, and the aim has been to give the results of the best work of the ablest men. There are, therefore, given conflicting opinions, credited to authority, without attempt at harmonizing them; but in many cases the author has also stated his own convictions. The second edition represents a thorough revision of the first, with many additions that bring the work to date.

There is stated to be "substantial proof that in some infectious diseases heredity is traceable to direct transmission of the specific microbes floating in the circulation of the mother to the fetus, through the thin wall which separates the maternal from the fetal blood."

The existence of pathogenic microbes in the healthy body is spoken of as "probable." These may apparently remain inactive until a trauma or some pathological product supplies a convenient field for their growth. When the skin is intact the suppuration of a tumor or hyperplastic lymphatic gland is accounted for by abnormal vascular conditions that have served to arrest floating microbes.

The various microbic diseases that are met in surgical practice, such as tetanus and erysipelas, are in turn considered. An interesting chapter is that devoted to "Clinical Forms of Surgical Tuberculosis." The disease described by Rosenbach, under the name of erysipeloid, is also noticed. Quite justly the microbic origin of tumors is considered still unproved. The author narrates an experiment of his own in transplanting carcinomatous tissue from an infected to a healthy locality in the human subject. The graft united, but was afterward completely absorbed. The same result was obtained in his twenty-four experiments on animals. The following is his concluding opinion: "There has been, so far, no

proof furnished of the existence of a specific bacillus in carcinoma or sarcoma, and the inoculation and implantation experiments have proved so seldom successful, and the experiments which at first appeared successful have later been shown to be so deceptive, that the microbic origin of malignant tumors has not only not been established, but rendered improbable."

The book represents a great deal of labor in summarizing the work of others, particularly of German and French investigators. Indeed, this is one of its chief recommendations, as the reader has an opportunity to arrive at the best opinion with but little labor. Abundant references are conveniently incorporated in the text.

NEWS ITEMS.

Annales d'Oculistique. — This long-established and widely known ophthalmological journal, conducted during many years with distinguished ability by the late Professor Warlomont, has, since the death of that illustrious leader in ophthalmology, passed into the editorial hands of Drs. Valude and Sulzer, who have transferred the office of publication from Brussels to Paris.

The new management has doubled the size of the journal and promises to increase its usefulness.

Dr. George T. Stevens, of New York, the American collaborator, will report matters of ophthalmological interest from the United States.

Those who are familiar with *Annales d' Oculistique* will marked already have observed in the last two numbers a change in the prominence given to American literature.

The Philadelphia Polyclinic has issued its Ninth Annual Announcement, a survey of which affords an indication of the substantial progress that this institution has made in the comparatively few years of its existence. With a strong corps of teachers in the various general and special departments of medicine, selected from the best active men in the local profession, and with a commodious building, liberally equipped and specially adapted to its purposes, the Polyclinic has already become an important factor in medical education, and gives promise of increasing that importance.

The Southern Surgical and Gynecological Association will hold its annual session at Richmond, Va., November 10, 11, and 12, 1891. An interesting scientific program has been provided for. Dr. L. S. McMurtry, of Louisville, is the President; Dr. W. E. B. Davis, of Birmingham, Ala., Secretary; and Dr. Hunter McGuire, of Richmond, Chairman of the Committee of Arrangements. Members of the medical profession are cordially invited to the meeting.

Cremation.—Cremation is coming more and more into favor in Germany. In addition to the crematorium which has been in operation at Gotha since 1877, and where from five to six hundred bodies are cremated annually, and another which was recently established at Hamburg, a new one was recently consecrated at Ohlsdorf, and another at Carlsruhe.

Contributions to Mechanico-Therapeutics and Orthopedics is the name of a new publication to be devoted to the objects indicated by its title, under the editorship of Dr. L. Wischnewetzky. The first number contains, in addition to an editorial preface, a monograph on The Mechanico-Therapeutic Institute, by Dr. Gustaf Zander, of Stockholm.

American Orthopedic Association.—The following officers were elected for the ensuing year: President, Dr. Benjamin Lee, of Philadelphia; Vice-Presidents, Dr. R. H. Sayre and Dr. H. L. Taylor, of New York; Corresponding Secretary, Dr. Royal Whitman, of New York; Secretary and Treasurer, Dr. John Ridlon, of New York.

Latent Tuberculosis,—A prize of three thousand francs ($600) has been offered for the best essay on the subject of "Latent Tuberculosis," to be presented to the next Congress of Tuberculosis, which will probably meet in 1893.

A Pasteur Institute in Cochin China.—A Pasteur Institute was opened at Saigon on June 1st, under the auspices of the French Government. Though primarily intended for the practice of anti-rabic inoculation, the work of the institute will extend over the whole field of microbiology.

A Bacteriological Institute is to be established at St. Petersburg, in accordance with a decree of the Czar, who has allocated a considerable sum for the purpose. Dr. Gabrylowicz, of Vienna, is to be the director.

Dr. Alphons von Rosthorn, of Vienna, has been appointed temporary Director of the Obstetric and Gynecologic Clinic of the University of Prague, *vice* Schauta, elected to succeed Braun at Vienna.

The Editorial Committee of the *University Medical Magazine*, Drs. G. E. de Schweinitz and Edward Martin, resigned on the first of October, and in their places were elected Drs. J. Howe Adams and A. C. Wood.

Death from Epsom Salts.—The *British Medical Journal* reports the case of a woman who, feeling ill, took four ounces of Epsom salts at a single dose and in an hour was dead.

Dr. Woods Hutchinson, of Des Moines, Iowa, editor of the *Vis Medicatrix*, has been elected Professor of Anatomy in the Iowa State University.

Professor Franz Exner has been elected to fill the chair of Physics at the University of Vienna, to succeed Goldschmidt, who retires, seventy years old.

Professor Moos has been elected Ordinary Honorary Professor in the Medical Faculty of the University of Heidelberg.

Professor Rubner, of Marburg, has succeeded Professor Koch in the chair of Hygiene at Berlin.

Dr. Ogner has been elected Professor Extraordinary of Comparative Anatomy at the University of Moscow.

Professor August Gartner, of Jena, has accepted the chair of Hygiene at Marburg.

Dr. John M. Keating has taken up the practice of medicine at Colorado Springs, devoting himself to the treatment of the diseases of women and children.

Surgical and Mechanical Treatment of the Deformities Following Infantile Spinal Paralysis. By De Forest Willard, M.D., Ph.D. Reprint, 1891.

Two Cases of Removal of Laminæ for Spinal Fracture. By De Forest Willard, M.D. Reprint, 1891.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM OCTOBER 13 TO OCTOBER 19, 1891.

APPEL, DANIEL M., *Captain and Assistant Surgeon.*—Is granted leave of absence for one month, to take effect about the 6th proximo.

By direction of the President, ARTHUR W. TAYLOR, *Captain and Assistant Surgeon*, will report in person to Colonel John Mendenhall, Second Artillery, President of the Army Retiring Board, at Fort Adams, R. I., for examination by the Board.

BEALL, GEORGE T., *Captain and Medical Storekeeper.*—Is granted leave of absence for one month. During the absence of Captain Beall, Charles B. Ewing, Assistant Surgeon and Attending Surgeon at St. Louis, Mo., will take charge of the Medical Purveying Department in that city.

GANDY, CHARLES M., *Captain and Assistant Surgeon.*—Is relieved from duty with the Army Medical Board, to take effect on its final adjournment, and ordered to Fort Yellowstone, Wyoming Territory.

SUTER, WILLIAM N., *First Lieutenant and Assistant Surgeon.*—Is relieved from duty at Fort McKinney, Wyoming Territory, and ordered to Fort Grant, Arizona Territory, for duty.

MCVAY, HARLAN E., *First Lieutenant and Assistant Surgeon.*—Is relieved from duty at Fort Mackinaw, Michigan, and ordered to Fort Wingate, New Mexico.

GLENNAN, JAMES D., *First Lieutenant and Assistant Surgeon.*—Is relieved from duty at Fort Riley, Kansas, and ordered to Camp Oklahoma, Oklahoma Territory.

IRELAND, MERRITTE W., *First Lieutenant and Assistant Surgeon.*—Is relieved from duty at Jefferson Barracks, Mo., and ordered to Fort Riley, Kansas.

BENHAM, ROBERT B., *Captain and Assistant Surgeon.*—Is relieved from duty at Fort Hamilton, New York, and ordered to Mount Vernon Barracks, Alabama, for duty.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING OCTOBER 17, 1891.

MAGRUDER, A. F., *Surgeon.*—Ordered to the "Boston."

DIXON, W. S., *Surgeon.*—Detached from the "Boston," and granted leave for two months.

MARSTELLER, E. H., *Passed Assistant Surgeon.*—Ordered to special duty at Baltimore, Md.

DRAKE, N. H., *Passed Assistant Surgeon.*—Detached from the "Albatross," and granted leave for two months.

WIEBER, F. W. F., *Passed Assistant Surgeon.*—Detached from the "Pensacola," and ordered to the "Albatross."

BRADLEY, GEORGE P., *Surgeon.*—Detached from Naval Hospital, Chelsea, Mass., and ordered to the Receiving-ship "Wabash."

BRAITHWAIT, F. G., *Assistant Surgeon.*—Detached from the "Wabash," and ordered to Naval Hospital, Chelsea, Mass.

BEYER, H. G., *Passed Assistant Surgeon.*—Ordered to Naval Academy, Annapolis, Md.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U. S. MARINE-HOSPITAL SERVICE, FOR THE THREE WEEKS ENDING OCTOBER 19, 1891.

VANSANT, JOHN, *Surgeon.*—Granted leave of absence for twenty-three days, October 8, 1891.

LONG, W. H., *Surgeon.*—Granted leave of absence for thirty days, October 7, 1891.

HAMILTON, J. B., *Surgeon.*—To represent the Service at the meeting of the Mississippi Valley Medical Association. October 2, 1891.

GASSAWAY, J. M., *Surgeon.*—Leave of absence extended for five days, September 28, 1891.

WHEELER, W. A., *Passed Assistant Surgeon.*—Granted leave of absence for thirty days, Ocrober 7, 1891.

PECKHAM, C. T., *Passed Assistant Surgeon.*—To represent the Service at the meeting of the Mississippi Valley Medical Association, October 2, 1891.

BRATTON, W. D., *Passed Assistant Surgeon.*—Granted leave of absence for thirty days, October 7, 1891.

PETTUS, W. J., *Passed Assistant Surgeon.*—To proced to Norfolk, Va., for temporary duty, October 2, 1891.

MAGRUDER, G. M., *Passed Assistant Surgeon.*—Granted leave of absence for twenty days, October 7, 1891.

WOODWARD, R. M., *Passed Assistant Surgeon.*—Granted leave of absence for thirty days, October 6, 1891.

VAUGHAN, G. T., *Assistant Surgeon.*—Granted leave ot absence for thirty days, October 6, 1891.

COBB, J. O., *Assistant Surgeon.*—To proceed to Buffalo, N. Y., for temporary duty, October 7, 1891.

GUITERAS, G. M., *Assistant Surgeon.*—To proceed to Mobile, Ala., Pensacola, and Mullet Key, Fla, on special duty, October 10, 1891.

BROWN, B W., *Assistant Surgeon.*—To report to the medical officer in command, San Francisco, Cal., for duty, October 3, 1891.

COMMUNICATIONS are invited from all parts of the world. ORIGINAL ARTICLES.

SEVEN RECENT CASES OF BRAIN-SURGERY.[1]

BY WILLIAM A. HAMMOND, M.D.,
OF WASHINGTON, D. C.

THE following cases of operations performed upon the skull and brain for the relief of cerebral disease, occurring since the subject of brain-surgery has developed into an art approaching exactness, will, I think, prove of interest to the Association. Besides these, I have trephined thirty-one times for epilepsy with but one death, but as these operations were undertaken with reference more to supposed injury of the brain from obvious skull-lesions, and not from a consideration of the symptoms, I omit for the present further notice of them, merely calling attention to the fact that twenty-three of them are classified in my *Treatise on Diseases of the Nervous System.*

The cases, however, of which I am now about to speak are of somewhat different character, because not only was the seat of a real or supposed injury a factor in determining where to operate, but the symptoms, their nature and location, were even of more importance in deciding upon the situation of the disease, the consequent point on the skull with which it was in relation, and the extent to which the operation should be carried.

CASE I.—J. V. had several years previously been under my care for epilepsy, the apparent consequence of a blow with a stone received when he was eight years old. The peculiar feature of his disease was that he was a subject of double consciousness, passing suddenly from the normal to the abnormal condition, during which he was apparently in full possession of his reasoning faculties, but of which, when he emerged therefrom, he had no recollection. Upon one occasion he started from New York to go to Indianapolis, but when he came to himself he was in England and had been there for several weeks. During this time he conducted himself in an entirely orderly and rational manner. Upon another occasion he was absent from home for three weeks, and when he recovered his consciousness he was in Baltimore living at a hotel and about entering into negotiations for the purchase of a bookstore. His conduct had been exemplary in every respect. In the interval between these seizures he was subject to the ordinary epileptic attacks both of the grand and petit mal variety. Under the influence of the bromides his attacks were arrested for over a year, but they finally returned, and on my advising an operation he determined to enter my Sanitarium at Washington for the purpose of having it performed.

At this time he was forty-one years of age, large, well-formed, and of good habits. Upon examination a depression was found in the skull, involving the right parietal bone near its posterior superior angle. At this place there was almost constant pain, but there were no symptoms, such as paralysis of motion or of sensibility, referable to any other part of the body. The depression in the bone was an inch and a quarter in length, and I determined that the center of it was immediately over the fissure of Rolando and the horizontal portion of the ascending frontal and the ascending parietal convolutions. I operated on the 15th of April, 1889. Anesthesia was produced by ether. A semicircular incision was made through the scalp, the pericranium raised from the bone, and the trephine applied over the center of the depression. Upon lifting the button of bone it was found that there had been no fracture of the skull and that the dura mater was apparently in a healthy condition. The rongeur was used so that the entire opening in the skull was about an inch and a quarter in diameter. No evidences of disease, however, were discovered. In considering whether or not to open the membranes and expose the brain I was influenced by the consideration of the facts that although the injury to the skull was immediately over the superior part of the ascending frontal and ascending parietal convolutions there were no symptoms involving the power of motion of the upper or lower extremities. I, therefore, came to the conclusion that there was no injury or disease of these convolutions and that it would be inadvisable to expose the brain. Accordingly, the wound was closed without any of the bone being replaced and the patient made a rapid recovery, the whole wound uniting without suppuration. Twice during the subsequent week, the scalp having become puffy, the fluid, consisting of bloody serum, was drawn off by means of a large hypodermatic syringe. Although the patient was better at the Sanitarium at the end of the second week, and remained without pain or seizure for three months, both eventually returned and he is now about in his usual condition. I think that if I had to do this operation over again I should pare off the surface of the convolutions, especially in the light of the subsequently developed fact that there has been no improvement in the patient's condition.

CASE II.—J. H., thirty-five years of age, entered the Sanitarium May 13, 1889, being unable to walk or to lift the right arm; the tendon reflex of knees,

[1] Read before the American Neurological Association, Sept 23, 1891.

especially of the right, was much exaggerated; ankle-clonus was well marked on both sides; voluntary muscular power of right arm and leg was almost entirely abolished, but with sensation apparently unaffected. Upon examining the head a large depression of the bone was found over the left parietal eminence. This was due to a blow from a saber during the war. Subsequently a large piece of bone exfoliated. He remained in comparatively good health until about seven years ago, when he began to drag the right leg in walking and to lose power in the right arm. He occasionally suffered from pain in the head at the seat of the injury. The paralysis of the right arm and leg gradually increased until nearly complete, when he came under my observation. About two years previously to his entering the Sanitarium his voice began to acquire a higher pitch than was natural and there was considerable difficulty of speech due to impairment of the power of the muscles of articulation, especially those of the lips. So far as the mind was concerned, the intellect did not seem to be materially enfeebled, but his emotional faculties were weak, just as they so frequently are in persons that have suffered from cerebral hemorrhage. A slight thing made him shed tears profusely. There was no history of syphilis. I regarded the paralysis of the arm and leg and exaggerated reflexes to be due to degeneration of the left antero-lateral column of the cord, and that there was probably also a corresponding condition in its incipiency involving the right antero-lateral column. In regard to the brain-lesion and the consequent disease I did not venture upon an exact diagnosis, but I was inclined to believe that the membranes had been the seat of inflammation, and that the cortex of the ascending frontal and ascending parietal convolutions had likewise been involved. The difficulty of speech, arising as it did mainly from impaired motor power of the lips, indicated that the center for the movements of these organs, the posterior part of the middle frontal convolution, was likewise implicated. He improved to some extent under treatment, consisting mainly of iodide of potassium and electricity, but this was not sufficient to warrant a hope of cure from such measures, and on May 20th I performed the operation of trephining.

The patient was etherized, and a semilunar incision was made in the scalp. The trephine was applied so as to include the center of the depression, which was about two inches in extent antero-posteriorly, and embracing within its limits parts of the ascending parietal, ascending frontal, and middle frontal convolutions. Several spicules of bone were found adherent to the button removed by the trephine. By means of the rongeur, the opening of the skull was enlarged to about the size of a silver dollar. Several fragments of depressed bone were found united to the portion removed. The opening in the skull now included all of the injured portion. There was a thick mass of false membrane adherent to the bone taken away. This I dissected off, leaving an apparently healthy membrane below. This membranous mass was quite vascular, so that its removal occasioned considerable hemorrhage. A drainage-tube was inserted into the wound at its posterior angle, since, notwithstanding the antiseptic measures employed, I was apprehensive that the necessary violence used might lead to suppuration. Nevertheless, the union was complete throughout by the third day, and the tube and sutures were removed. The patient made a perfect recovery, without fever or inconvenience of any kind.

Almost immediately improvement was manifested both in the paralyzed arm and leg, so that by June 12th he was able to walk fairly well with a cane and could raise his arm to his head. Electricity (faradic) was applied to these parts. The voice had become much stronger, and the movements of the lips were such that he could now speak without stammering. The tendon reflex of the left side was still somewhat exaggerated; the ankle-clonus was materially lessened. He continued to improve until June 17th, when he left the institution sooner than he ought to have gone. I have had no information of a direct character, but have understood that he continued to improve for several weeks after he left the Sanitarium, when he again gradually grew worse.

The beneficial effects of the operation were in this case clearly manifested. Doubtless the involvement of the spinal cord and the motor paralysis were due to pressure exerted upon the ascending parietal, the ascending frontal, and middle frontal convolutions. A second operation might have been advisable.

CASE III.—L. T., female, aged three years, entered the Sanitarium on May 13, 1889, the subject of epilepsy, from which she had suffered about a year, and that had resulted, not only in her inability to acquire a further power of articulation, but in loss of ability to use the words that she had already learned. Though sufficiently intelligent for her age and quick in her movements, there was thus an entire loss of the faculty of speech, and epileptic convulsions occurred about once a month. There was the history of a fall from her nurse's arms, and her mother attributed the convulsions and the loss of speech to the injury of the head then sustained. So far as any marks were concerned there was nothing to show that the skull, or even the scalp, had been injured, but the mother was very clear that the blow had been received on the left side of the head, immediately above the ear. I advised trephining, and, the parents consenting, the operation was performed on May 22, 1889. My object was to trephine the skull at a point about an inch in front of the fissure of Rolando, and about a quarter of an inch above its junction with the fissure of Sylvius, so as to be immediately over the posterior part of the third frontal convolution. No injury of the bone was found, but the portion removed was a quarter of an inch thicker than was normal, so that it doubtless exercised considerable pressure on the brain at that point. The dura mater was apparently healthy.

The wound healed throughout by first intention, without there being the slightest untoward symptoms. The child remained under my constant observation for several weeks. She had no fit during this period, and was beginning to talk when she left

the institution. Improvement in the faculty of speech, as I learned by several letters from her mother, was continuous, and she now (at a little over five years of age) speaks as well as most children of five years old. There has been no convulsion in all this period, and, to all appearance, the child is in perfect health. The last letter from her mother stated that the child's uncle came into the room a few days previously, and remarked jocosely that he was "going to send the girl to Dr. Hammond to have something done to stop her talking."

In this case I do not know to what to attribute the remarkable success of the operation, unless to the fact, as I have stated, that it relieved an existing pressure on the center for articulate speech.

Case IV.—Miss G. entered my Sanitarium on July 20, 1890, suffering from an old left hemiplegia, epileptic convulsions, mental deterioration, and occasional paroxysms of maniacal excitement. The clinical history is briefly as follows:[1] The patient was nineteen years of age, her father an Italian, her mother an American. The family history was good, the father and mother healthy, and there was no history of syphilis. The patient was born healthy and normal. During an attack of cholera infantum at five weeks of age she became rigid, the arms and legs contracted and flexed, in more pronounced degree on the left side than on the right. The right side recovered, but the left side remained more or less contracted. She had an epileptic attack at five years of age, and another at six. After that the convulsions became more frequent, occurring at intervals of from one to six months.

For the last five years she has exhibited marked symptoms of mental derangement, committing many singular actions and being very passionate, excitable, silly, and weak-minded. Examining her on admission to the Sanitarium, I found that both mind and body were undeveloped. The left hand was in a state of extreme flexure and was permanently contracted. The whole extremity was in a state of atrophy, and there was not a muscle that was not more or less paralyzed. The left lower extremity was in a similar state, though in a much less degree.

The left side of the face was much less mobile than the right.

I gave it as my opinion that she was suffering from a morbid growth of some kind, involving the left parietal lobe and part of the frontal lobe, especially the ascending parietal convolution and the ascending frontal convolution. Though almost hopeless, I expressed my willingness to undertake an operation for the patient's relief.

A horseshoe incision with the convexity directed posteriorly was made; flaps of integument and pericranium were raised and an inch-trephine applied so that the center-pin was fixed on the line of what I had determined to be the course of the fissure of Rolando and about half an inch inferiorly to the sagittal suture. The crown of the instrument was intended to embrace within its limits that portion of the skull immediately over the superior part of the ascending frontal and ascending parietal convolutions.

The button of bone was removed and the dura mater, arachnoid, and pia mater were found to be adherent to each other. A bluish membrane now protruded, very much resembling in appearance the longitudinal sinus. Renewed examination showed that it could not be this vessel, and it was at once punctured with a sharp-pointed bistoury. Immediately a stream of serous fluid, free from odor, spurted out as if from a syringe to a distance of two or three feet, and continued to flow for about ten minutes with diminished force. The wound in the membrane was enlarged to the extent of half an inch and a probe was introduced; it could be passed downward and forward for about two inches without meeting with an obstruction.

A drainage-tube was introduced and at once the fluid began to flow more freely. The tube was introduced along the line of the fissure of Rolando and passed in for three inches without meeting with obstruction. The button of bone was not replaced, but the wound was closed around the drainage-tube, which was left in place and through which fluid still continued to flow.

Soon after being put to bed the patient had a severe chill, which was controlled by applying bags of hot water to the body. On emerging from the state of anesthesia the patient was noisy and excited and complained of some pain in the head. The temperature varied from 100° to 104° on the 28th of July, when she died in a state of coma on the sixth day after the operation.

At the post-mortem examination adhesions were found to exist between the right frontal lobe and the frontal bone; there was also thickening of the dura mater throughout the course of the longitudinal sinus, extending for about an inch on each side. Nearly the whole of the right parietal lobe and upper and posterior part of the frontal lobe seemed to have disappeared, for the membranes were greatly collapsed. The membranes were found thickened throughout their whole extent and were strongly adherent to the base of the skull and to each other. A cyst was found coëxistent with nearly the whole right parietal lobe, the convolutions of which portion had entirely disappeared. The ascending frontal convolution, except its inferior and horizontal portion, was also absent; otherwise the frontal lobe was in good condition. The anterior portion of the occipital lobe was also implicated, so that a portion of the middle and inferior convolutions had disappeared. Inferiorly it was ascertained that the cyst involved the temporal lobe, and that the superior temporal convolution and about one-half of the middle temporal convolution were absent. Further examination showed that not a vestige of the island of Reil remained, that the anterior and external thirds of the caudate nucleus and a like portion of the lenticular nucleus of the corpus striatum were absent, and that the internal capsule was greatly atrophied. Continuing the dissection, it was discovered that

[1] The report of this case in full will be found in the New York Medical Journal of September 27, 1890.

the cyst was separated from the lateral ventricle anteriorly by a very thin lamina of cerebral tissue.

A second cyst of about the size of a large almond and involving the inferior convolution was also found to exist. There were no cerebritis, no recent meningitis, and no hemorrhage.

It is thus seen that the diagnosis was substantially correct, though the lesion was much more extensive than there was any reason to suspect. Probably the original disease was an extensive meningitis, the arachnoid being especially implicated in the regions where the cysts were discovered. It is certainly remarkable that life should persist for nearly nineteen years under such a condition of brain-disease. The fact of the destruction of the island of Reil is interesting in connection with the circumstance that it was on the right side and that there had been little speech-disturbance. In other respects it is seen that the case is strikingly corroborative of the doctrine of cerebral localization as laid down by Nothnagel, Ferrier, Exner, and others.

In regard to the cause of death I have no very satisfactory explanation to offer. The patient had fully recovered from the shock of the operation, there was no recent inflammatory action anywhere in the brain or its membranes, and the wound was in a perfectly healthy condition, the scalp having united, as I have said, throughout nearly its whole extent. An examination of the lungs and kidneys was not permitted, but there is no room for thinking that these organs were in a state of disease.

Case V.—T. K., thirty-eight years of age, entered the Sanitarium October 8, 1890, suffering from epileptic convulsions and partial paralysis of the left upper and lower extremities. Twenty years previously he had fallen from a height upon a marble floor and sustained a fracture of the skull involving the posterior superior angle of the right parietal bone. No operation was performed at the time, but several pieces of bone came away spontaneously, so that when he came under my notice there was a fissure in the skull at the point indicated, irregularly triangular in shape and about the size of a half-dollar coin. There was a good deal of cicatricial tissue and the scalp was depressed at its lowest depth, fully a quarter of an inch below the level of the surrounding parts.

He entered the Sanitarium for the purpose of having the operation of trephining performed, understanding perfectly that the operation might not only prove unsuccessful in relieving him of his symptoms, but might also result in his death. I was under the impression that there was a cyst at the point of injury, and that this was covered by the brain and scalp at the parts where the bone was deficient, and that possibly there were some fragments of bone that ought to be removed. A semilunar incision with its convexity directed forward was made in the scalp, and the crown of the trephine was applied to the bone so that its edge not quite touched the lower border of the fissure. The removal of the button of bone was followed by a gush of serous fluid, and by passing a probe in all directions I then discovered that there was no brain-injury in contact with the scalp, nor with the skull to the extent of over an inch in circumference from the opening made by the trephine. As a result of the original injury, therefore, there had been a large loss of brain-substance, and I had opened a cyst, the walls of which consisted externally of the cerebral membranes, the skull, and the scalp. Judging from the large amount of fluid that exuded, I had no doubt that this cyst communicated with the lateral ventricle.

The patient rallied from the operation, but became very weak and faint shortly afterward—the result, doubtless, of the loss of so large a quantity of cerebro-spinal fluid. I, therefore, removed the drainage-tube which had been inserted and closed up the wound throughout its whole extent. By the third day it had entirely united by the first intention; the fluid, however, continued to increase in quantity so that it was necessary to tap the scalp several times in order to drain it off. Coincidentally with this, increased somnolence, approaching stupor, was developed, but this condition disappeared at once on the evacuation of the fluid. At no time during the course of treatment were there any evidences of inflammation, but the patient continued to grow weaker and at times was slightly delirious, though he improved to such an extent that he was able to sit up and take a drive of several miles into the country. He gradually sank until he died, November 28th, fifty days after the operation, and apparently from sheer exhaustion. He had no convulsion after the operation, but there was no improvement in the paralysis either of the upper or lower extremity. The only other change observed was a remarkable slowness of speech, a sort of staccato articulation, but there was at no time any indication of aphasia. The cyst was rather superficial, but it was about two inches and a half in its horizontal diameter and three inches and a half in its vertical diameter.

Case VI.—W. H., twenty-eight years of age, entered the Sanitarium October 21, 1890, suffering from left hemiplegia, epilepsy, and imbecility. The diagnosis in this case was cerebral syphilis, and he was treated with large doses of iodide of potassium, hot douches to the spine, and electricity. The iodide was carried to the extent of half an ounce three times a day. He improved from the very beginning of the treatment, and on January 18th went to his home in Texas free from all abnormal symptoms. He had had no convulsions in all this time, although they had previously occurred at the rate of two or three every week. The hemiplegia entirely disappeared and his mind was restored to its naturally good condition. My opinion was that he was suffering from a gummatous tumor of the cerebral cortex involving the ascending frontal and ascending parietal convolutions, and that under the use of the iodide of potassium absorption had taken place. But in March, 1891, all the symptoms gradually returned and he was again brought to the Sanitarium for treatment and entered the institution May 30th. At this time he was the subject of repeated convulsions, he was unable to walk from complete paralysis of the left lower extremity, and from like cause the arm was entirely helpless. His mind was a

complete blank, and at times he was distinctly maniacal. He could not give an intelligent answer to any question, and exhibited all the indications of suffering severe pain in the head, apparently on the right side. I at once began the administration of the iodide of potassium, though it was not carried up to the extent of over two hundred grains three times a day, but without benefit, the symptoms persisting in all their original intensity. I therefore determined to trephine him so as to expose the centers for motion of the left upper and lower extremities, namely, the right ascending frontal and ascending parietal convolutions. On removing the button of bone and laying open the dura mater the membranes were seen to be opalescent and a small quantity of serous fluid escaped. As there were no indications of a growth at this point, and as the revealed condition was such as would probably be relieved by the operation, I decided not to proceed further. The wound was, therefore, closed, and it united entirely by first intention without the occurrence of a single untoward symptom.

The patient began to improve at once, mentally and physically, and on August 15th returned home as well as he had ever been in his life.

The success of the operation in this case was marked, but was due, not as I supposed it might be, to the removal of a morbid growth, but to the relief which it gave to the pressure exerted upon the brain by the inflamed membranes, and the small amount of fluid that had collected. Whether or not the improvement will continue is, of course, a matter of conjecture; but, as a measure of precaution, I have instructed the man to use the iodide of potassium in large doses every alternate month during the next two or three years.

I regard this case as most instructive, because I have no doubt that the condition discovered bore the relation of a cause to the symptoms; and that such cases can be relieved by the comparatively safe operation of trephining is a point in cerebral pathology and cerebral surgery of very great interest.

Case VII.—W. K., twenty-eight years old, entered the Sanitarium originally on December 19, 1890, suffering from a constant, dull, heavy ache in the occipital region, with occasional attacks of vertigo. The pain was so severe in character as utterly to unfit him for his business, and he had been compelled to refrain from all mental work. He had suffered for over two years when he came under my observation. Examination showed the kidneys to be healthy, and that there were no disturbances of sensation or motility in any other parts of the body. Speech was unaffected, and the intellect was unimpaired in all its parts. Seven years previously he had been struck by a stone in the right frontal region, about an inch above the supra-orbital ridge, and a cicatrix and a depression existed at this point. He was stunned by the blow, and was insensible for several days, but made a good recovery without an operation. There was no pain in this region, however, and I did not associate the injury with the pain in the back of the head from which he suffered. No treatment, however, that I gave him proved of the slightest benefit, though I continued it for several months after he left the institution.

But, on reflecting upon the case, I resolved to submit to him the propriety of an operation, and, with a full knowledge of the uncertainty of the result, he at once consented to have me trephine the skull at the point of injury. He therefore reëntered the Sanitarium on July 30, 1891, and on August 2d I operated. On raising the button of bone that corresponded with the most depressed portion of the cicatrix, I discovered a large spicule of bone attached thereto. Passing a probe between the skull and the dura mater around the opening, I could discover no other evidences of fracture, but there was a mass of highly vascular membranous tissue, from the necessary injury of which some two ounces of blood were lost, and I was obliged to ligate a vein as large as a crow-quill, from which the blood was flowing in full stream. I was afraid to remove this mass with the knife on account of the hemorrhage that I knew would result, and, moreover, I found that the bleeding had caused it to shrink to a great extent. But, with the fingers and the handle of the scalpel, I detached the greater part of it and then closed the wound. By the third day the union was complete throughout and the patient at once expressed himself as being greatly relieved. On the fourth day I allowed him to leave his bed, and on August 13th he returned home, relieved, but by no means cured. A letter, however, received from him a few days since, states that the improvement has continued, that the pain has almost entirely disappeared, that he feels mentally bright and active, and is desirous of resuming his business.

This case is also extremely interesting, and the success obtained is in the highest degree instructive. If the symptoms from which this patient suffered had been such as to endanger his life, or had been more extensive than they were, I should have removed a greater portion of the skull and carried my exploration much further than I did, but I did not consider myself justified in thus seriously increasing the risk of a fatal result for the relief of mere pain.

NOTE UPON A POSSIBLE SERVICE TO BE EXPECTED FROM DIURETIN IN GENITO-URINARY SURGERY.[1]

By EDWARD L. KEYES, M.D.,
of New York.

Outside of the usual complications liable to attend any cutting operation, the surgeon who deals with the genito-urinary tract has to contemplate, and if possible guard against, that other mysterious concomitant of operations upon the urethra and

[1] Read at the meeting of the American Association of Andrology and Syphilology, held in Washington, September 22–25, 1891.

bladder, known under various names, and often called "urinary fever."

The theories about it are numerous. In the present connection it does not interest us to ascribe it to urinary intoxication, shock, kidney-congestion, or to any special cause. It exists. We all recognize it, we all fear it, and—I speak for myself—we do not thoroughly understand it. Let me illustrate: Of a considerable number of supra-pubic, perineal, and urethral operations, performed during the past year, I have lost only one. Many of the cases were, to all appearances, infinitely more desperate than this one. A number of them had albumin, casts, pus, and blood without stint, in the urine; yet all other cases recovered. This fatal one was in an old gentleman, the father of a prominent physician. His urine was as clear as crystal and free from albumin, and his bladder contained no pus. A year before my operation he had his urethra divulsed up to an enormous size, and very large sounds were used without a chill or any bad symptoms. His life, however, had become a burden by reason of the necessity for repeated use of the catheter. The cystoscope showed a minute third lobe, with a moderately healthy bladder. I cut this patient above the pubes. I nipped off his minute third lobe, which stuck up as large as a small marble in the internal urethral orifice. There was no bleeding; he took a moderate amount of the anesthetic; he had been catheterized constantly and divulsed before without accident, yet, within half an hour after my operation, he had a chill and absolute suppression, from which he never rallied. This was, I believe, pernicious urinary fever. Why did he have it? I do not know, nor can anyone tell me to my satisfaction. I did not give this patient diuretin. I did not know about it at the date of my operation upon him.

To prevent urinary fever various things have been done: all kinds of preparation of the patient, and the use of drugs—notably aconite, pilocarpine, quinine, etc.—ordered. I never thought well of aconite; I did once confide in pilocarpine, but gave it up. I have long since ceased to use quinine; I now never administer it before an operation, believing it to be absolutely devoid of value. Local urethral antisepsis I believe to be also much overrated. Germ-killing in the various urinary passages is a praiseworthy pursuit, but perhaps more difficult than those who pretend to follow it conceive it to be. There are two methods, one of which tries to render the passages pure by antiseptic irrigation from below; the other essays to purify the stream at its source, by the administration of various substances, notably salol, boric acid, naphthalin, saccharin, the benzoates, etc. Added to this, the instruments are disinfected, and then the requirements of modern surgery have been complied with—yet none of these methods secures us against urinary fever. They doubtless aid in so doing, and are useful as far as they go. Cleanliness and disinfection are as essential now to successful surgery as anatomical knowledge, manual dexterity, and general experience—but none of these is final in eliminating the possibility of urinary fever. Instruments and hands can be perfectly disinfected, the urine and the urinary passages not so. Albarran,[1] Guyon's first and very able assistant, has shown that the urine passed by patients who have absorbed large quantities of salol has no bactericidal power, and contains pathogenic microbes. Lavaux's conclusions, derived from experiments in washing the urethra, are not based upon bacteriological examinations, and therefore lack convincing value, as pointed out by Petit and Wasserman[2] in their study of urethral antisepsis. These gentlemen, at the instigation of Guyon, undertook some experiments in urethral antisepsis by the direct method, and inoculated bouillon tubes with mucus taken from the urethra after thorough irrigation with sterilized water, 4 per cent. boric acid, and 1 : 1000 nitrate of silver. In every instance the inoculated tubes showed numerous microörganisms at the end of a week. These gentlemen, therefore, concluded, from a laboratory standpoint, that irrigation as ordinarily practised is without reliable value, even if continued half an hour, in that it does not secure complete asepsis of the urethra.

Yet this conclusion need not dishearten us. Why should we expect to wash out all the germs from a canal so permeated with glandular ducts, each one capable of holding enough bacteria to poison an army. As well may one decry the value of the mercuric bichloride against the gonococcus, because it does not kill them all at a single application—a manifest impossibility, since they are protected in the depths of the tissues and in the glandular follicles.

But this article is not to detract from the value of the means that we have to render urethral and bladder surgery more safe. It is to suggest another, in the hope that there may be value in it.

In June last I went to a city near New York to take a large stone from the bladder of an old gentleman, and at the same time to remove an outstanding third lobe. His case was desperate. He had suffered long, and for four years he had been an invalid, spending most of the last year in bed, taking opium suppositories, and passing his catheter hourly sometimes, and again at longer intervals. He could not urinate at all without the catheter. I cut this patient above the pubes, and took out a stone as large as an egg and a prostatic third lobe as large as the last joint of the thumb. The bladder was thin-

[1] Ann. des Mal. des Org. Génito-urinaires, January, 1890.
[2] Ibid., July, 1891.

walled, corrugated, trabeculated, and sacculated. I put my finger into holes on each side which seemed like ureteral orifices, but did not stop to investigate closely. They could not have been orifices of the ureters, because these are closed even when the ducts are enormously dilated. His urine had been like gruel, full of albumin and all sorts of detritus. There was no question of there being dilated ureters, pyelitis, and more or less interstitial nephritis on both sides. The operation was done simply because it had to be done in compassion for the old man's sufferings. The outlook was desperate.

I thought, then, of trying diuretin, and telephoned for it before the patient recovered from his anesthetic, ordering 10 grains to be given at once, and frequently repeated. This patient got well. He had considerable nausea from morphine given hypodermatically, but no chill and no suppression, and his physician, Dr. Tieste, writes, on September 1st, that "he is able to hold his water from five to seven hours, and to pass it without a catheter, a thing that he has been unable to do for three years."

Since that time I have used diuretin in every case of urethral or bladder operation that has fallen under my hands. I give 60 grains of salol per day for forty-eight hours before operating, and commence diuretin on the day of the operation, giving it also in doses of 10 grains every four hours for forty-eight hours. I, of course, irrigate the bladder and urethra; I did this before, but my results have been better since using the diuretin. If this is a coincidence, time will demonstrate it; if not, it is proper that this Association should have an opportunity to experiment, and either verify diuretin as an adjuvant to urethral and bladder surgery, or prove its lack of value. I do not here assert that it has great value, or any, but I do state that it does no harm, and that since commencing to employ it, now less than three months, I have used it in every major operation that I have performed, and my assistant, Dr. Fuller, has used it twice, and in no instance has there been any urinary fever proper—that is, there never has been a chill or a suppression. The cases cover all ages from eighteen to eighty, with desperate complications, such as pyelitis, urine loaded with albumin and casts, diabetes, etc. Patients have had shock, fever sometimes, and various complications, but never chill or suppression. The number operated on is 13; not large, it is true, but it was in the summer season, and all were private patients. The time is too short for generalization, but when it is remembered that the cases were: Supra-pubic prostatectomy, 6; supra-pubic lithotomy (diabetes), 1; perineal section, 3; perineal section without guide, 2; litholapaxy, 1; mostly in old men with damaged kidneys, all of whom recovered without chill or any tendency to suppression, it is fair to imagine that the means used had something to do with it, and the diuretin is the only new drug. In three of the cases there was profound shock after the chloroform (which I now always use), but the kidneys acted all along.

Was it the diuretin that did the service? I do not know. Time must decide.

Diuretin being a new substance, I may briefly say that it is theobromine and salicylate of soda (a combination sometimes ascribed to Gram, of Copenhagen), a white powder of sweetish, saline, alkaline taste. E. Merck, of Darmstadt, first manufactured it at the instance of Prof. Riegel, of Giessen University, some time prior to 1890. It is soluble in hot water and in warm diluted alcohol. The same or a similar salt was first brought out in the *Apotheke Zeitung*, December 14, 1889, under the name of diuretin. This is believed to contain 50 per cent. of theobromine, and is soluble with heat in half its weight of water, remaining in solution on cooling. Theobromine is the alkaloid obtained from the seeds of theobroma cacao, and is also found in the kola nut. It is related to caffeine, the latter being the methyl derivative of theobromine.

Diuretin appears to be a free diuretic, seemingly pretty constant in its action. It does not irritate the stomach, bowels, or nerves, and does not depress a weak heart. Reports about it therapeutically vary, as is natural in the case of all new drugs, but it seems safe, and worthy of trial in order to see what it will do. The dose is 10 to 15 grains often repeated, to 90 or even 120 grains a day, given in powder or in pill form—preferably gelatin-coated pill, as the powder deteriorates on exposure. If it will prevent, or even moderate urinary fever, it is a valuable drug. I hope to report a more extended experience with it next year.

REPORT OF TWO CASES OF EPILEPSY, WITH ALBUMINURIA, MISTAKEN FOR UREMIC CONVULSIONS.[1]

By JAMES TYSON, M.D.,
PROFESSOR OF CLINICAL MEDICINE IN THE UNIVERSITY OF PENNSYLVANIA.

It has happened to me twice in a comparatively short time to be consulted in two cases of convulsions, associated with albuminuria, which were supposed to be uremic, but which proved to be true epileptic fits. The albuminuria in each case was responsible for the diagnosis made. In one of these cases two well-trained physicians were misled for a considerable time, and I held a like opinion with them until, in the course of a more prolonged study of the case, the truth dawned upon me. The second case was not so misleading from the outset, and with the light of my first case was easily recognized.

[1] Read at the sixth annual meeting of the Association of American Physicians held at Washington, September, 1891.

The first patient was a married woman, aged fifty, who had had one child, a girl sixteen years old, at the time the case came under my notice. There was no sign of renal trouble during pregnancy, and no complication during or after labor. An aunt on the mother's side died of tuberculous phthisis, and an aunt on the father's side of rapid consumption. The patient had one brother who was a confirmed epileptic. When seventeen years old, Mrs. H. had cough and hemorrhages, said to be from the lungs, for which she was treated with cod-liver oil. They ceased, and no other allied symptoms presented themselves. A few years before the illness about to be considered, she spat blood several times, but as she was approaching her climacteric her brother, who was a medical man, was not alarmed. In 1885 she had a spell of simple dysuria, the first in her life, which also passed off without any untoward effect apparent at the time.

On Saturday, December 11, 1886, she was attacked with severe headache, accompanied by great nausea. The headache was such as she had never before experienced. It continued for three days, but gradually abated, and by the 15th had nearly disappeared. At 8 o'clock on the evening of this day, however, she had a severe convulsion, during which she bit her tongue. She had a second at 12 o'clock, a third at 2 o'clock, and a fourth at 4 o'clock in the morning. The convulsions were controlled by chloroform, used as seemed to be required.

The urine at this time was scanty, contained a small amount of albumin and some pus, but no tube-casts were found. The convulsions were regarded as uremic, and she was placed upon a milk diet.

I was consulted concerning her on January 20th following (1887), when the urine was first sent to me for examination. It was a pale-yellow fluid, with a sp. gr. of 1015, feebly acid; contained a mere trace of albumin, and a small white sediment composed of pus and vaginal epithelium. No casts were found. I did not see her, however, until February 2, 1887, with Dr. William Savery and Dr. John W. Lodge. She was in bed for greater convenience of examination, but had been up, and, indeed, had not the aspect of a sick woman. Since her attack on December 15th she had been on a milk diet. The urine examined at this time (February 2d) was 1010, again contained a trace of albumin, and in the course of examining six slides I found two hyaline casts and one granular cast.

She continued to improve in general health without incident until a day or two previous to the 12th of March, when she had another attack of headache, less severe than the first, but accompanied by dizziness and noise in the ears. These symptoms gave rise to some apprehension, but were not followed by anything more serious. The urine was again examined; at this time it had a sp. gr. of 1015, contained a very decided sediment of pus, fully $\frac{1}{15}$ its bulk; again there was a very small quantity of albumin, but slightly more than at the previous examinations, $\frac{1}{50}$ the bulk being noted. The increased albumin was reasonably explained by the increased amount of pus. In addition to the pus-cells there were a few columnar cells, but no casts were found.

In the latter part of July, Mrs. H. had a rather severe attack of diarrhea, in which I attended her, on account of the absence of her brother. It was ushered in by a sharp headache, and as this had been the forerunner of her first attack of convulsions some apprehension was again felt, and it was thought best not to check it too suddenly. No convulsion occurred, but after she had recovered, and was sitting up, her daughter described a sudden momentary unconsciousness, during which a fall was arrested by her opportune presence. This was on the 27th of August, 1887. An examination of the urine at this time discovered a sp. gr. of 1017, the same flocculent sediment composed of pus-cells and epithelium, a single undoubted hyaline cast, and the same small quantity of albumin.

On November 20th, she had a severe fit, on account of which I was called, but she had come out of it by the time I reached her, being still, however, somewhat dazed. I saw her several times in the course of a couple of days, but there was no recurrence of the fit for nearly a year (September 20, 1888), although there was what was called "a threatening" a few days earlier. Another fit occurred December 22, 1888, April 8, 1889, and again December 6, 1889.

In the latter part of June, 1890, Mrs. H.'s attention was attracted by the presence of blood in her urine, unattended at first by other symptoms. The hemorrhage continued until June 28th, when it had become quite copious. In my absence from the country, my friend, Dr. Horace Williams, was called. To the hematuria was added now severe pain over the region of the bladder and in the right flank. The urine, loaded with blood, became also very scanty, as small a twenty-four-hours' quantity as twelve ounces being recorded.

Just when the bloody urine was assuming a brownish tint, the blood becoming replaced by pus, she had a slight chill, about 6.30 on the morning of the 2d of July, and at 5 o'clock the next morning a terrific chill, the temperature running up to 104.8°. By evening of the same day the temperature had fallen to 100.6° F., and by the next morning was normal. All the symptoms then began to subside, and on the 9th of July she was sitting up. During the entire period of her serious illness there was no suggestion of a convulsion, while the ninety grains of potassium bromide which she had been taking daily for months had been discontinued, and at the end of ten days, when she was deemed thoroughly convalescent, she had a single epileptiform convulsion. About August 1st, she went to Wernersville, Pa., and while there, on August 18th, had a single typical convulsion, and two days later what the family called "a threatening," in which she lost consciousness for a few seconds only—analogous to other minor attacks referred to.

She, however, rapidly regained her health; and on examination of her urine by myself, September 23, 1890, it exhibited the same small sediment of pus and trace of albumin. Another examination in July revealed the same state of affairs. After the

bromide was recommenced in the summer of 1890, she continued taking thirty grains three times a day.

On the 16th of June of this year I was sent for to see Mrs. H., because of a suspected attack of the usual kind, although she seemed not to have lost consciousness. There was no sign of anything wrong when I reached her. She is now apparently in good health, but has a shrinking, gentle manner which seems to me more or less characteristic of epileptics.

The second patient alluded to, also a woman, Mrs. R., was forty-eight years old, and had four children. Her father died of apoplexy, and her mother of a tumor of the stomach. In childhood she had an attack of diphtheria, and was subject to sore-throat. Seventeen years ago, at the birth of her second child, there was albuminuria, but no other serious symptom, and the albumin soon disappeared from the urine. It, however, returned from time to time, but in the meantime a third child was born without albumin being discovered, and without other complication. No albuminuria was reported in her third pregnancy, nor in her fourth; but four months after the birth of her fourth and last child, and while in apparently perfect health, she had her first convulsion. This was eleven years ago. The fit was a very slight one, lasting but a few seconds; there was twitching and a smacking of lips, but she was scarcely unconscious. During the seven years that followed, she had about half a dozen more fits at odd intervals. In the four years subsequently she had none until January 1, 1890, when she had a very severe one, preceded by what she calls dizziness, possibly an aura. From that date to September 12th, when I first saw her, she had no convulsion, nor has she had any to date.

At the suggestion of Dr. Brush she called upon me in September, 1890, and I elicited the above history. She described most of the attacks as being very short, and as consisting largely of what she described as a peculiar sensation lasting not more than a minute, during which she could hear her own voice making imperfect efforts at speech. The inability to speak properly continued several minutes after consciousness returned.

Her object in consulting me was to determine the nature of these attacks, the more especially as a distinguished member of this Association, whom she consulted in 1880, said she had Bright's disease, and would not live more than two years, probably only one. Ten years later she consulted Dr. Bartholow, of Philadelphia, who said that the attacks were epileptic. This view was held also by Dr. Brush, who sent her to me for an opinion.

In September, 1890, the evening and morning urine were examined on two separate occasions by myself, and each time a trace of albumin was found, but no sediment of any significance. The twenty-four-hours' urine ranged from forty to fifty-four ounces.

Under the circumstances, I did not hesitate to declare the peculiar seizures to be epileptic, and that the albuminuria had nothing to do with them. With regard to the milder attacks, the question might indeed be raised as to whether they may not have been hysteroidal attacks, of which Dr. H. C. Wood says: "They seem to be very close to epilepsy, and also to hysteria." And, like these, their true character is to be determined by the history of the case and the occurrence of more severe attacks of undoubted epileptic character in the present instance. A recent letter from Mrs. R. informs me that she had none since the violent attack of January, 1890, although she had during the past winter the "dizzy turns" described.

In further illustration of the possibilities of the situation, my friend, Dr. J. Hendrie Lloyd, related to me lately his experience with a similar case. Toward bedtime one night he was sent for in great haste by the servants to see the head of a family with the ills of all the members of which he had supposed himself well acquainted. Responding promptly, he found the gentleman, who was past middle life, in terrific convulsions, which he at once concluded were uremic. No others of the family except the servants were at home, and he could obtain no information. One attack succeeded another at close intervals, during which the patient lay in a comatose or semi-comatose state. My friend was, however, able between two paroxysms to secure a specimen of urine. Hasty examination failed to discover albumin, but the constant association of contracted kidney with small and scarcely detectable albuminurias, only went to confirm his conclusion that he had to do with a case of uremic convulsions. He remained throughout the night. The patient's wife was expected early in the morning, and he dreaded to meet her because of the sad prognosis he felt forced to make to her. He, however, gravely informed her of what had transpired, and she replied nonchalantly that he had been having similar attacks for twenty-five years!

Is there any way of avoiding similar errors? So far as any peculiarity of the convulsions themselves is concerned, I believe not. Uremic convulsions differ in no way from epileptic convulsions. They are, in fact, typical epileptic convulsions, and exhibit the same varieties and degrees presented by such convulsions. In both, the tongue is lacerated, both exhibit a degree of violence at once alarming and revolting. On the other hand, both may be so mild as to be barely noticeable, and both may be followed by periods of stupor of longer or shorter duration, or by a sudden return to the natural state. But true uremic convulsions do not repeat themselves at intervals for months and even years at a time, and yet leave the patient apparently no worse for his or her experience. And if true epileptic convulsions happen to be accompanied by albuminuria, such albuminuria does not, as a rule, remain at a stand-

still or grow gradually less, but increases and is gradually associated with other phenomena of chronic Bright's disease, such as hypertrophy of the left ventricle, edema, visual derangements, headache, high vascular tension, dyspeptic symptoms. When a history is obtainable of previous attack, it will generally be found that there has been a harmlessness of consequences following the pure epileptic convulsion which does not belong to the uremic fit.

CONGENITAL CLUB-FOOT, WITH ABSENCE OF THE GREAT TOE AND CONTIGUOUS BONES OF THE RIGHT INSTEP.[1]

BY T. M. L. CHRYSTIE, M.D.,
OF NEW YORK.

THE case herewith reported is of interest by its bearing upon the causation of congenital talipes of the equino-varus variety, since there are absent the parts that are supposed to produce the varus deformity of the tarsal arch or instep. The twist or varus of congenital talipes is said to be due to the drawing of the inner side of the foot upward and backward toward the leg by the contraction of the two tibial muscles, the tendons of which passing respectively in front of and behind the inner malleolus are inserted at the inner margin of the sole of the foot; the tendon of the tibialis posticus being inserted at the inner and under surfaces of the scaphoid and internal cuneiform bones, and that of the tibialis anticus at the inner and under surfaces of the internal cuneiform bone and the base of the metatarsal bone of the great toe. In this case, these muscles, as well as the bones (except the scaphoid) affording them attachments, are absent, yet, as shown by the photographs, there is an otherwise typical case of the deformity, the correction of which had been unsuccessfully attempted by at least two skilled medical men during more than two years.

The child was brought February 14, 1891, aged two years and five months. He was carried, though I was told he could walk while wearing a shoe into which was incorporated a steel structure; but in a few hours the use of this made the apex of the varus too sore to be continued. The deformity of the foot attracted so much attention that the presence of only four toes was not usually noticed. The gastrocnemius was extremely and firmly contracted, but the front part of the foot was so twisted upward and inward that the patient, by placing the foot in advance and throwing back the knee, could rest his weight on the posterior part of the foot sufficient to steady his body, but not securely enough to stand or walk. His efforts in this direction were damaging the knee and upper part of the limb. Absence of the first row of the phalangeal bones and the first shaft of the metatarsus was made out at the first examination, but the absence of the internal cuneiform bone was discovered only after correcting the deformity.

Treatment was begun February 20, 1891, by partially correcting the tarsal deformity by hand, and placing the uncovered foot in a steel brace bearing on the inner side of the foot and leg, with a steel sole pressing the plantar surface of the metatarsus upward, the counter-pressure coming from a web strap passing over the tarsus aided by a compress; the leg was firmly grasped by a lacing of leather cut to include the external malleolus. The brace was removed twice in twenty-four hours to bathe the parts briefly in a solution of tannin and alcohol, but the foot was not allowed to lose any of its position. As the foot was gradually forced out of its deformity, corresponding changes were carefully made in the apparatus. In a week the brace was adjusted to remove the contraction of the gastrocnemius muscle, much of it being done by manual force at two or three sittings; and at the end of four weeks the foot was in correct position. There was no pain, discomfort or chafing, and after the first week the child walked nicely. The resistance in this case was as firm and unyielding as in another case of congenital talipes equino-varus, aged one year, under treatment at the same time, in which there had not been any arrest of development and the tibial muscles were present and strongly contracted. The foot in each case furnished a similar resistance to correction, and there was the same successful result in each. This demonstrated what has always seemed to me apparent, that the contraction of the tibial muscles is not the obstacle to be overcome and that their division is unnecessary.

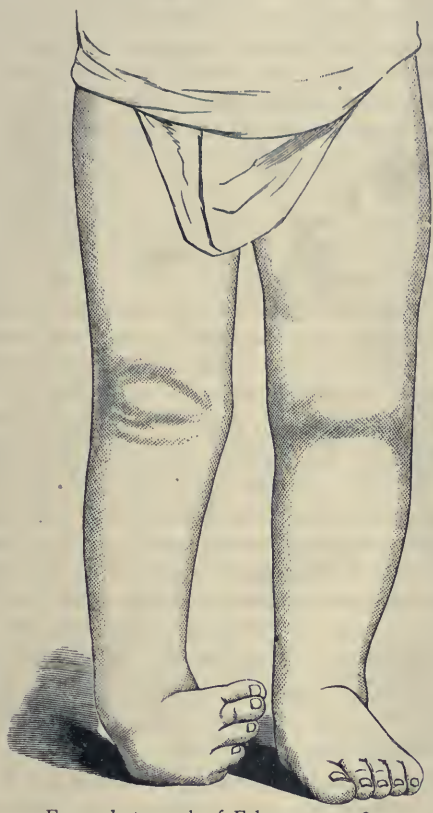
The child is active and intelligent, and in other respects well developed and healthy; he has two older brothers well formed and healthy, except a recent indirect hernia in the second boy. His mother is healthy and well formed, though small in height; her pregnancy was natural, except that she did more sewing than usual during the latter part of gestation; the birth was normal. The father, I am told, presents a deformity at the upper part of the spinal column, dwarfing him, but he is otherwise active and in good health, a dentist by occupation. The mother's uncle had hare-lip, and one of his children had extensive arrest of development of both upper and lower extremities, though in other respects healthy and still living.

The photographs show the foot before and after the correction of the deformity. The patient can extend and by the extensor communis digitorum flex his remnant of a foot, and has now use of foot and limb without any defect of gait. The right

[1] Read at the meeting of the American Orthopedic Association, held in Washington, September 22–25, 1891.

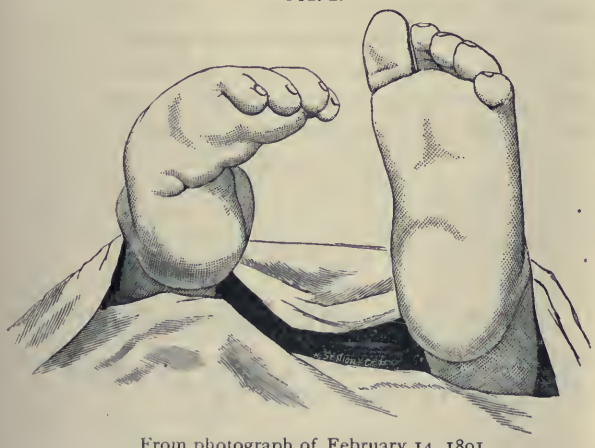
leg below the knee is three-quarters of an inch less in circumference than its mate, owing to the absence of five of the thirteen muscles of the leg. The absence of the great toe is responsible

Fig. 1.



From photograph of February 14, 1891.

Fig. 2.



From photograph of February 14, 1891.

for the absence of three, the peroneus longus, the extensor, and the flexor proprius pollicis; and the absence of the first shaft of the metatarsus and the internal cuneiform are responsible for the absence of the two tibial muscles. Measurements about the malleoli show six inches for both sides. The scaphoid bone is not fully formed, and since the removal of the deformity has not developed apace with the rest of the foot. The limbs are the same

Fig. 3.

From photograph taken September 12, 1891.

in length, but it remains to be seen if the right limb will grow at the same rate as its more favored mate. It now has a chance, though it has against it eighteen months of disability and injury from the deformity of the foot, the efforts to use the limb on so unsteady a base resulting in hyperextension and strain of the knee-joint, and an injury to the nutrition of the entire limb, from the glutei muscles down.

PRE-COLUMBIAN SYPHILIS.

By ALBERT S. ASHMEAD, M.D.,
of New York.

In view of the interest awakened in pre-Columbian matters by the approaching Fair in Chicago, the question of the history of syphilis in America is just now receiving a great deal of attention. Dr. James Nevins Hyde, in the *American Journal of the Medical Sciences*, discusses the question whether the North American Indians of pre-Columbian times left any evidences in their bones of syphilitic disease. Many—Dr. Shrady among them—think that we have been too ready to accept the compliment paid by the ancient continent to the new in crediting it with the origin of the disease. Dr. Hyde reports the results of some microscopical studies by Dr. Prudden, on two tibiæ from Colorado, which showed the presence of chronic formative ostitis and periostitis, which, as Dr. Shrady observes, might or might not be of syphilitic origin. They conclude that as yet the story has not been told by the bones.

Professor Brinton, the American paleontologist, thinks otherwise. In a letter that I am authorized to make use of, he says: "The origin of syphilis is still an open question. It seems to me probable that it existed time out of mind, in both the New and Old worlds, but assumed a peculiarly malignant form in Europe at the close of the fifteenth century. Certainly, in America, syphilis of the bony system existed before the discovery, as is shown by the relics in ancient graves." Again he says: "Whether it was peculiar to the American continent and was carried to Europe by the sailors of Columbus, etc., as has been argued, is a separate question. I am inclined to think that it really existed in both continents, but for reasons unknown abruptly assumed a malignant type in Europe at the close of the fifteenth century."

The researches of Mr. Gozo Tateno, the Japanese Minister to Mexico, have nothing to do with bones. In his opinion the Aztecs of Mexico and the Japanese belonged to the same race. The physical, and even the philologcal affinities, are extremely striking. I do not know how much importance ought to be attached to the fact that such simple words as "adobe" (sun-dried brick), "coa" (snake), and "huarache" (shoe), are both Japanese and Mexican. But the fact is certainly curious. It is to be hoped that Mr. Tateno will some day publish all the results of this very interesting investigation.[1]

Quatrefages also believes in the consanguinity of the pre-Columbian Americans and the Asiatics. The latter have, of course, been carried to our shores by the Japanese Black Stream. The Behring Straits might even have given passage to a Chinese invasion. It is an undoubted fact, which must corroborate this opinion, that America was known to the Chinese long before Columbus. They called it Fousang. We find in their books some very striking presentments of that very characteristic animal, the llama. The same books speak of Buddhistic efforts at proselytizing in Fousang in the fifth century. Buddhist symbols, representative of Asia, are found in pre-Columbian American art. The Japanese called the same country Fouso, and the same missions are mentioned in their literature.

Quatrefages might have strengthened his theory by showing some almost evident Japanese vestiges in old Peru—for instance, the belief that the rulers of the land, the Incas, were descended from the sun, while we know that the Japanese consider their country as the sun's cradle (Nippon); and the custom of burying the dead in a sitting posture. We owe to trustworthy travellers the interesting information that a Japanese dialect was spoken in certain early Californian colonies. Mr. Guillemin Taraire affirms it of a tribe of Santa Barbara; moreover, he says that the language of several others includes some Japanese and Chinese words. These are not the only philological facts of that kind of which we know. I may mention here that the Hon. John A. Bingham, who was our Minister in Japan for thirteen years, told me that he had found a great many similarities between American-Indian dialects—for instance, of Ohio—and the Japanese language. It must be remembered that Ohio was probably one of the most inhabited cantonments of the pre-Columbian population, for it is one of the places in which most of the remains left by the ancient mound-builders have been found. The word Ohio itself is, perhaps, Japanese "good-morning." Even as far east as Pennsylvania we discover philological affinities. Glen Onoko, near Mauch Chunk, was formerly called by the Indians Otaki. Both words, Onoko and Otaki, are Japanese, and mean "male" and "great waterfall." In Japan, when two waterfalls are situated close together, the great one is always called the male, the small one the female.

Here is another fact, not philological: The different kinds of Indian arrow-heads in the National Museum at Washington have been compared to those forms of arrow-heads that were used by the old Japanese. There is a striking correspondence. All the Indian types are represented in ancient Japan. Yet in no other case does a comparison of Japanese arrow-heads with those of other tribes show any remarkable degree of similarity.

Even if we had only such facts, each not so very strong, perhaps, but very numerous, we might think it highly probable that the American races were descendants of the East Asiatics. In that case it would be equally probable that syphilis existed in America many centuries before the advent of Columbus, for this disease without doubt was known in Japan as early as the seventh century at least. We have for the latter statement the authority of the "Ishinpo," a Japanese encyclopedia of Chinese medical works, 589–807 A. D., by the great Japanese professor of acupuncture, Tamba. There are other authorities no less weighty.

[1] Mr. Tateno is a native of Osaka, and speaks the dialect of Western Japan.

CLINICAL MEMORANDA.

A CASE OF MERCURY-POISONING BY AN ANTISEPTIC TABLET.

BY WILLIAM CLINTON SHEEHY, M.D.,
OF NEW BEDFORD, MASS.

M. V., a sailor, thirty-three years old, while at sea suffered from constipation, and was advised by a shipmate to "take a pill." He was unable to read English, and without advice he took from a bottle a white tablet, which afterward proved to be an antiseptic tablet con-

taining hydrarg. chlor. corros. 7.7. gr., amm. chlor. 7.3 gr.

On the evening of August 29th, three days afterward, I was called. His companion stated that he broke the pill with his teeth and washed it down with a small glass of water. About half an hour afterward, he was seized with vomiting. A sense of nausea with occasional vomiting, the vomitus sometimes containing blood, persisted for twenty-four hours. It was the appearance of blood that alarmed the captain and caused him to bring the boat to port. The bowels, which had moved but *once*, became the seat of much severe griping pain. The tongue, teeth and gums showed all the characteristic symptoms of violent mercurial poisoning, and the breath was very fetid.

The man had experienced a great deal of pain and burning in the esophagus, and had, therefore, taken no solid food. He had a violent headache, a temperature of 99⅘°, but a good pulse. I ordered potass. iod. gr. v, every four hours, and potass. chlor. gr. v, every four hours, given separately, and had the mouth washed every hour with a solution of potass. chlor. (gr. x to ℥j). On August 31st, he complained of some soreness and swelling about the submaxillary glands; but this had disappeared the next day. Under the potassium iodide, which I had increased to ten grains every four hours, he felt worse, but a full dose of magnesium sulphate caused a disappearance of the symptoms. Flaxseed tea was very gratifying to the patient, and under the continued use of potassium iodide, free purgation, and a milk diet, he did well.

I consider this case interesting because I believe that a good part of this strong bichloride solution must have been absorbed. The broken tablet was certainly in the stomach long enough to become dissolved. In this connection it is to be noted that there was neither purging nor eruption, results that usually follow the ingestion of large doses of mercury.

REMOVAL OF THE VERMIFORM APPENDIX FROM A CHILD TWENTY-TWO MONTHS OLD, FOR SUPPURATIVE APPENDICITIS; RECOVERY.

By J. E. SUMMERS, Jr., M.D.,
PROFESSOR OF SURGERY, OMAHA MEDICAL COLLEGE; SURGEON TO THE CLARKSON MEMORIAL AND IMMANUEL HOSPITALS, OMAHA.

I HAVE carefully searched the literature at my command for the report of a case of appendicitis, with removal of the appendix, in a young child, and finding none I feel justified in recording the following case, more especially since the tables of Matterstock and Fitz show the disease to be very rare before the third year. Indeed, according to Fenger (*Cyclopedia of the Diseases of Children*), the youngest case of appendicitis was in an infant seven weeks old. On post-mortem examination, there was found a diffuse peritonitis and "the appendix was dilated and filled with adherent, firm, solid, concrete-like fecal masses." No perforation was discovered. Silbermann saw a case of peritonitis the result of perityphlitis in a child in the late period of lactation. Matterstock mentions a case of perityphlitis in a seven months' old boy, and he and Fitz each report cases in children of twenty months.

Fitz found that out of 247 cases of the disease among children, 80 per cent. were in males and 20 per cent. in females. Matterstock, in 72 cases of children, found the disease in 51 males and 21 females; 70⅘ per cent. and 29⅕ per cent. respectively.

Thus we see that the disease commonly designated perityphlitis, usually having its starting-point in the vermiform appendix, an appendicitis, is almost unknown before the third year, and although not uncommon after that age in children, it occurs much more frequently among males than females.

On the morning of the 27th of July last I was requested to see a twenty-two months' old boy, with the view of performing an abdominal section for the relief of a supposed intestinal obstruction. The history of the case, as given by the attending physician, was as follows:

Four days previously he saw the child soon after it had been seized with what he judged to be an attack of colic. Visiting the child again after a few hours, the existence of a serious lesion was recognized; the pulse was very rapid and the temperature 104° F. There was marked abdominal distress, frequent vomiting, and the bowels were constipated. The child was just recovering from an attack of summer diarrhea. On the second day a consultant saw the case and diagnosticated some obstructive trouble about the head of the colon. Although the temperature had gone down, ranging from 100° F. to 101° F., the pulse was still proportionately too fast. The abdominal symptoms continued more or less pronounced, requiring opium. The bowels had been moved several times by enemas, the dejections containing much mucus. From the second to the fourth day, it had been impossible to obtain a movement of the bowels by enema, and also a cathartic, given by the father without the physician's direction, had failed to act. A small tumor situated in the right abdominal region had been recognized.

On the morning of the fourth day I saw the case for the first time. The pulse was 140, the temperature 101° F., the abdomen somewhat distended and painful, more especially over the region of a small tumor situated with its greater part above McBurney's line. There was no special point of tenderness. The tumor was evidently not adherent to the parietal peritoneum. The child had the general appearance of being very ill. I diagnosticated a suppurative appendicitis, and advised immediate abdominal section. The possibility of an intussusception was considered.

Everything being in readiness and the patient chloroformed, I made a digital exploration by the rectum, and finding nothing to aid the diagnosis, stepped into the bath-room to wash my hands, when upon returning I found that my rectal exploration, aided by the anesthetic, had accomplished what repeated injections failed to produce, a copious, natural movement of the bowels. The surprise of the father and others present, who had had obstruction of the bowels well impressed upon their minds, was so great that I had some difficulty in getting consent to proceed with the operation.

It was done, however, in the usual manner. The incision was made in the right linea semilunaris. The tumor, agglutinated intestines, and omentum were isolated from the general peritoneal cavity by the care-

ful packing of iodoform gauze between the parietal peritoneum and the intestines about the tumor. The omentum was then separated from the surface of the tumor and the intestines gently teased apart until the escape of the characteristic, stinking pus indicated the opening of an abscess. After several drams of pus had escaped, the separation of the intestines was continued until the appendix was recognized, when it was freed from its adhesions, brought up into the incision and tied off from its mesentery and close to the cecum by a double silk ligature, and then cut away. It was much enlarged, in part gangrenous, and contained three perforations. No foreign body could be discovered. The protective packing of gauze was removed and renewed. In addition to some of this same material, a drainage-tube was introduced in the region of the abscess. The usual dressings were applied, but no sutures. In twenty-four hours most of the gauze was removed, and the wound lightly packed. On the fourth day the patient was chloroformed, all gauze removed, and the wound closed by sutures, except its lower angle. The convalescence dated from the day of operation and was uneventful.

I have since operated successfully upon a boy eight years of age for a similar lesion. The appendix could not be recognized; otherwise the operation and after-treatment were practically identical with those in the case narrated.

STRANGULATION OF VAGINA THROUGH A RING-PESSARY.

BY FRANK W. THOMAS, M.D.,
OF PHILADELPHIA.

THE following case is reported to call attention to an unlooked-for danger in the use of certain forms of ring-pessaries.

Mrs. L., sixty-eight years old, was badly torn at her last confinement, and for the past sixteen years has suffered from complete procidentia uteri, to which condition, owing to extreme modesty, she had never called the attention of a physician. A chronic endometritis and ulcerated cervix finally led her to complain, and she was persuaded to seek medical aid. Examination revealed a perineum torn almost to the sphincter, the uterus and inverted vagina protruding from the vulva, the os dilated and ulcerated from friction, and a thick muco-purulent discharge flowing over the parts and excoriating the adjacent tissues. The patient refused operative aid, and a support, having an external attachment, was suggested. For many reasons the "Cutter" support (a ring one and a half inches in diameter, with a lateral stem) was selected. This gave great comfort for two or three days, when it became displaced and was replaced by a neighboring (untrained) nurse. An hour later the patient was suffering agony and I was summoned. The uterus and inverted vagina were again protruding and presented a swollen and purple appearance, with distended veins. The stem of the support was found between the arch of the pubes and the anterior inverted vaginal wall. With some difficulty the finger was guided along the stem and the ring was found to be surrounding and constricting the vaginal tissues at the fundus of the uterus, which had fallen through the lumen of the ring. Careful and diligent manipulation for half an hour failed to free the mass. Filing through the ring was tried in vain, and as a last resort, a pair of ordinary garden shears was brought into requisition, and the ring cut through at the stem and at the opposite side. The tissues were freed, the protruding mass replaced, antiseptic vaginal washes used, and the os supported on a McIntosh cup. Since this time (September 25, 1891) the patient has done well.

Senile atrophy of the uterus is the probable explanation of this rare accident, which might have proved so serious, but the occurrence should warn us of the necessity of taking into consideration the nature and size of all the pelvic contents before applying a support. If in a similar case I should need a like support, and in order to use cleansing douches I hesitated to apply the "cup," I should modify the "Cutter" by having a narrow (one-quarter inch) hard-rubber band extending across the lumen of the ring, which would prevent hernia and allow irrigation.

"THE PROTECTIVE" IN ANTISEPTIC DRESSINGS.

BY D. BENJAMIN, M.D.,
SURGEON TO COOPER HOSPITAL, CAMDEN, N. J.

WHAT is known as "the protective" in antiseptic dressings is a piece of silk very much like the common silk court-plaster, or isinglass-plaster, with this difference, that it is not so stiff, and is, or rather is supposed to be, sterilized.

The manner of using it is to carefully lay over the line of incision a strip sufficiently long to extend at least half an inch beyond each extremity and wide enough to extend at least a quarter of an inch beyond the sutures on each side of the wound. This constitutes the first part of the antiseptic dressing for the wound, and upon this the antiseptic gauze is placed; the antiseptic or absorbent cotton follows, and then the bandage. Some use a powder either on or under "the protective."

To obtain the best results in antiseptic surgery "*the protective*" *should never be used;* it is so impervious, especially if well applied, that instead of keeping the edges of the wound together it prevents the escape of the effusions and thus dams them up, causing pressure and separation of the edges of the wound. If "the protective" be left off the wound altogether, the antiseptic gauze absorbs the exuded fluids, keeping the wound nicely drained and dry.

Moreover, if there happen to be a few germs under "the protective" they readily multiply in the pent-up secretions, thus kindly protected from all the influences of the bichloride gauze, with its many absorbent layers laden with the germicidal mercury. My advice therefore is: *Do not use "the protective."*

Having sterilized the wound as completely as possible, after the sutures are cut and tied, apply the dry antiseptic powder, the gauze, the cotton and the bandage. Any "protective" placed between this dressing and the flesh, if it does anything, destroys or injures the usefulness of other dressings.

The Bacillus of Leprosy.—It is announced that Dr. Kantback, a member of the Indian Leprosy Commission, has finally succeeded in cultivating the bacillus of leprosy in artificial media.

HOSPITAL NOTE.

STITES'S TEST FOR CARCINOMA.

By JOHN H. BRINTON, M.D.,
PROFESSOR OF THE PRACTICE OF SURGERY AND OF CLINICAL SURGERY IN THE JEFFERSON MEDICAL COLLEGE OF PHILADELPHIA.

On October 17th, at the surgical clinic, I removed for atrophic scirrhus the right breast of a female, aged sixty-one. In the presence of the class the tumor was immediately subjected by Dr. W. M. L. Coplin to the test of Mr. H. J. Stites, of Edinburgh. The method of examination was that furnished me by Professor Chiene, of Edinburgh, which I give in his own words:

1. Excise the mamma.
2. Wash thoroughly in water to remove blood.
3. Place in a 5 per cent. solution of nitric acid (B. P.) for ten minutes.
4. Wash in cold water for five minutes.

By the time these procedures are executed the axilla is cleaned out and the vessels tied. The mamma is now examined; the carcinomatous structure appears a dull white, like the eye of a boiled fish, the healthy tissue translucent. When any such reaction is seen additional tissue should be removed at the corresponding point.

In removing the carcinomatous breast, Professor Chiene directs that its relations to the circumferential tissues should be marked by the knife, so that after the test has been applied to the mass excised the situation of any outlying, unremoved diseased areas can be fixed.

In the case operated upon the foregoing directions were carefully followed by Dr. Coplin, who demonstrated to the class that the infected tissue became of the characteristic "dull white," resembling egg-albumen, while the uninfected tissue appeared translucent and gelatinoid, affording a striking contrast to the carcinomatous structures. The reaction in the axillary glands seemed even more marked than that in the breast; it therefore would, perhaps, be well always to retain one gland for comparison with those treated with the acid.

The test described by the distinguished Scottish surgeon as devised by his assistant, Mr. Stites, appears to be a most perfect one. It is to be hoped that future trial will show that it can be depended upon, and that it can really be accepted as a gauge of the thoroughness and sufficiency of removal of carcinomata, not only of the mamma, but also of other parts.

CURRENT LITERATURE.

CURETTING THE UTERUS IN PUERPERAL FEVER.

Heinrich Fritsch maintains that the view that puerperal fever depends upon the invasion of the uterus by cocci leads to two indications: to prevent the entrance of the germs—prophylaxis; and to remove or render harmless such cocci as may have gained entrance.

If it could be known just when the germs had gained entrance into the genital passages, immediate or at least early washing out, cauterization and cleansing would be of service; just as the same procedures bring about recovery in operations for appendicitis and pyosalpinx, when rupture of the tube has taken place. When it is too late to obtain good results from irrigation, good may be accomplished by curetting the uterus. Such a mode of treatment would seem logically justifiable if puerperal fever be divided into pyemic, septicemic and sapremic. In the latter, septic processes are taking place in the uterus, with the presence of saprophytes and the ptomaïnes formed by them, the entrance of which into the circulation occasions fever. There is no doubt that the complete removal of the septic contents of the uterus in such a case must insure recovery. Fritsch admits that curetting is not especially dangerous, and states that it is not very painful. He thinks that there is little danger of perforation of the uterus, and seems to prefer a large, broad, dull curette. In the first few days after delivery, the uterus is usually firm and hard. Exceptionally, however, it may be soft and easily perforated. There are individual differences in this respect, and there are also local differences in the same uterus. Generally the uterus is more easily perforated later, in the fourth week.

In spite of the ease and harmlessness of curetting, Fritsch advises against it, because, at the beginning, sapremic puerperal fever is not to be differentiated from infection with streptococci. He has seen a large number of fatal cases of infection in which the fever set in between the fifth or eighth day, or later, and in which the mind was clear for days.

Again, in curetting, the true seat of the disease in the parametrium is not attacked. Infection begins in the cervix. When contraction of the uterus has taken place, the poison is beyond the reach of irrigation. The cocci enter through wounds in the cervix. So long as the cocci remain in the cervix they do little harm; interference may cause their dissemination and thus lead to the development of puerperal fever. In mild cases cleansing does good; so may also strong cauterization with iodine. Vigorous contraction of the uterus is helpful.

If fragments of placenta are adherent they should be removed with the curette, although Fritsch cites instances in which they seem to have occasioned no disturbance.—*Deutsche med. Wochenschrift*, No. 16, 1891.

DILATATION OF THE STOMACH FOLLOWING STENOSIS OF THE DUODENUM.

Hochhaus (*Berliner klin. Wochenschr.*, No. 17, 1891) concedes that it is easy to diagnosticate pronounced dilatation of the stomach, but maintains that it is often difficult to determine the causative factors. Among the latter are chronic gastric catarrh, atony of the muscular coat, obstruction at the pylorus and constriction of the duodenum. In some cases of narrowing of the duodenum large quantities of bilious matter are vomited.

In a case of narrowing of the jejunum, changes in the chemical reactions of the gastric fluids were noted. Sometimes, after a test-meal, the filtered gastric contents contained free hydrochloric acid and possessed normal digestive power; at other times hydrochloric acid was absent from the admixture of bile and the alkaline intestinal juice. Moreover, in spite of thorough washing-out of the stomach in the evening, profuse

vomiting nevertheless occurred during the night, due, no doubt, to regurgitation from the duodenum into the stomach.

Hochhaus reports three cases of obstruction of the small intestine. In the first, in a woman, sixty-seven years old, the main symptoms were eructations, flatulence, a feeling of tension in the epigastric region, and vomiting. The vomiting occurred at first two or three times a week, several hours after meals, but subsequently it took place in the late hours of the evening. A loud succussion sound could be heard over the stomach, with other evidences of dilatation. At times free hydrochloric acid could be found in the contents of the stomach; at other times the acid was wanting. The patient ultimately died of inanition. At the autopsy a tight stricture of the duodenum, just beyond the pylorus, was found, together with other evidences of ulceration resulting from the presence of biliary calculi.

The second case was in a man, sixty-seven years old, with vomiting of large quantities of a dark-greenish fluid, in which free hydrochloric acid was sometimes present and sometimes absent. The beginning of the jejunum was occluded by a colossal gall-stone. There were large scars in and a fistulous communication between the duodenum and gall-bladder.

In the third case, in a man thirty-four years old, with epigastric pains, eructations, and profuse vomiting of brownish masses, in which free hydrochloric acid was almost constantly present, a small carcinoma of the pylorus was found. The duodenum was additionally constricted at its lower part by cicatricial bands extending from the cystic duct.

Hochhaus believes that the chief diagnostic points of dilatation of the stomach following stenosis of the duodenum are:

1. The presence of a large quantity of bile in the stomach.
2. The variability in the presence of free hydrochloric acid and in the digestive power of the gastric juice.
3. Profuse vomiting in spite of careful washing-out of the stomach.
4. A history of disease of the biliary passages.

MEDICAL PROGRESS.

Antipyrine in the Treatment of Chorea.—LEROUX (*La Semaine Médicale*, August 12, 1891) obtained favorable results in forty-one of sixty cases of chorea treated with antipyrine. In the favorable cases, the disease terminated on an average at the end of forty-five days—the usual duration of chorea being sixty-six days. In nineteen cases, the results were not favorable, either because the disease proved refractory to antipyrine or was prolonged as post-choreic tic, or because the treatment was pursued irregularly, or was suspended on account of an intercurrent affection or of an intolerance of the remedy. Recurrences and relapses were, however, frequent, notwithstanding the continuance of the treatment. Forty-five grains (daily) constituted the minimum dose from which favorable results were obtained. In some instances, it was necessary to administer from sixty to seventy-five, and even ninety grains. The treatment was begun with from fifteen to thirty grains; for children of from eight to ten years, the dose was speedily increased to from sixty to seventy-five grains; for children of from ten to twelve, to from seventy-five to ninety grains. Some cases yielded at once to doses of from forty-five to sixty grains; but if at the end of from eight to ten days there was no change, the dose was increased in accordance with the age of the child. If, finally, at the end of a month doses of from seventy-five to ninety grains brought about no notable amelioration, no more was hoped for from its administration. Notwithstanding the prolonged administration of large doses of antipyrine, not a single grave accident occurred.

Incised Wound of the Femoral Vessels.—KRÖNLEIN (*Corresp.-blatt f. Schweizer Aerzte*, August 15, 1891) reported to the Society of Physicians of Zurich the case of a butcher, twenty-one years old, who had received an incised wound in the middle of the anterior surface of the right thigh, losing considerable blood before an Esmarch bandage was applied. The extremity became greatly swollen and the patient was anemic, almost pulseless, and excited. Without anesthesia, an incision was made at the site of injury and great masses of coagula removed. The femoral artery and vein were found severed; they were ligated with silk. Drainage was provided for; the limb was elevated, and a bandage was applied. In the course of twenty-four hours, fever developed; the wound became discolored and purulent; the limb was greatly swollen; the foot and leg became cyanotic. The sutures were removed. The bandages were changed twice daily, and the wound was irrigated with a solution of corrosive sublimate. Improvement gradually took place. Gangrene of the foot set in, a line of demarcation forming at the tarso-metatarsal line. Three weeks after the accident the condition of the patient was good; the temperature was almost normal, and the wound was quite clean.

Echinococcus in Joints.—FISCHER (*Deutsche Zeitschr. für Chirurgie*, Nos. 1 and 2, 1891) has reported the case of a man, forty-four years old, in which, following an injury of the lower end of the left thigh, great pain, swelling and fluctuation appeared at the knee-joint. An incision above and internal to the patella evacuated a considerable quantity of a thin, nearly clear fluid, with about a dozen echinococcus cysts. Swelling and fluctuation, however, returned. The knee-joint was then exposed and many echinococcus cysts with serous fluid were evacuated. The reddened synovial membrane and the suspected parts of the capsule of the joint were extirpated, the lower end of the femur thoroughly cleansed. Complete recovery ensued, with scarcely any impairment of the usefulness of the joint.

Anticylic Acid: a New Antipyretic.—MÜLLER (*Corresp.-blatt f. Schweizer Aerzte*, August 15, 1891), of Tokio, recommends anticylic acid as an active antipyretic. It is a white, fragrant powder, with a refreshing, acid taste, readily soluble in water, alcohol and glycerin, and is non-toxic. In a solution of 1 : 10,000 it is destructive of even the most resistant organisms. The solutions are clear and do not injure instruments. Administered internally in doses of gr. $\frac{1}{100}$, anticylic acid proved exceedingly useful in cases of pneumonia, typhoid fever and articular rheumatism.

SATURDAY, OCTOBER 31, 1891.

THE DISPOSAL OF LEPERS.

Within the past few years a considerable number of cases of leprosy, mostly subjects of foreign governments, have been brought to public notice in various parts of the country. Quite recently four cases have been discovered in Philadelphia alone. Two, by a fortunate combination of circumstances, were safely returned to their homes in South America; one is now in an adjoining county, and one is isolated in the Municipal Hospital. What to do with these unfortunate creatures is a subject for thoughtful consideration. The law prohibiting the admission of lepers into this country may be easily evaded when the disease is concealed, or not sufficiently developed to be readily detected. When in the country, the difficulty of returning the subjects of this malady to their native places is almost insurmountable. It remains, therefore, to devise a plan for the proper detention and care of lepers on our own soil.

It is no longer a disputed point that lepers should be isolated, and this isolation should be adapted to the peculiar needs of the patients suffering from this much-dreaded disease. While in a degree deprived of their liberty, the dictates of humanity repel the idea of isolation so absolute as to amount to imprisonment at solitary confinement. It therefore becomes necessary to provide stations for the special management and humane treatment of the subjects of this malady. Municipalities, or even States, are unequal to the task, for the reason that the expense would be excessive without apparent, corresponding advantages. An undue multiplication of such places, when only occasional necessity for their use exists, would make such a scheme impracticable. And yet, when the demand exists, the want of a local station is severely felt. Nor does it seem right that any municipality should be burdened with the expense, when the sufferers are almost invariably foreigners who have no permanent domicile, but move about from place to place as circumstances determine.

It would seem judicious and eminently proper that the National Government should take this subject in hand, and provide one or more well-selected stations, where all lepers could be sent under such regulations as would avoid any conflict with State prerogatives. Congress is soon to assemble, and if the representative medical societies and the Marine-Hospital Service, which is especially interested in the subject, would formulate the legislation necessary to meet the needs of the country, and follow up the first step by persistent effort and intelligent agitation of the subject, the solution of this question might be accomplished before another year passes.

METHYLENE-BLUE IN THE TREATMENT OF MALARIA.

In the *Berliner klinische Wochenschrift*, No. 39, 1891, Guttmann and Ehrlich, of the Moabit Hospital at Berlin, present an account of some very interesting and apparently valuable observations that they have recently made upon the therapeutics of malarial fever. In view of the fact that patients suffering from severe and prolonged attacks of this disease frequently acquire such a tolerance to the action of quinine that its therapeutic value is very much diminished, and at times even quite lost, these studies of Guttmann and Ehrlich will be of particular importance. They have tested the action of medicinal methylene-blue in this affection, and in two cases, one of quotidian, the other of tertian malarial fever, seem to have shown that the drug possesses curative properties. For some time past, chemists have been endeavoring to prepare synthetically some compound of the nature of quinine that may be substituted for it, but with only partial success. The behavior of the plasmodium malariæ when subjected to the action of methylene-

blue outside of the body in blood freshly drawn from malarial patients suggested its employment in this disease.

GUTTMANN and EHRLICH employed the drug internally, in doses of 0.1 gram (1.5 grains) five times daily. In the tertian form of the fever the interval between the doses was three hours, in the quotidian it was one hour. In the latter case its administration was begun about from ten to twelve hours before the appearance of the fever. The quantity administered daily should not exceed 0.5 gram (7.5 grains) and this should be continued for from eight to ten days after the disappearance of the fever.

The only unpleasant reaction that accompanies the use of the drug is a temporary irritation of the bladder, which rapidly passes away with the use of small doses of powdered nutmeg. The quantity of urine passed daily is also slightly increased. As yet, albumin has not been observed to be an accompaniment of this condition, though GUTTMANN and EHRLICH recommend that during the administration of the drug the urine should be carefully tested for albumin.

The urine passed during the treatment is seen to be of a bright-blue color. The intestinal evacuations, on the contrary, when passed, show no evidence of the presence of the drug, because of its presence as the colorless reduction-product, but upon exposure for a time to the oxidizing action of the air they too take on the characteristic blue tint. The prophylactic virtues of this compound have not, as yet, been determined. GUTTMANN and EHRLICH suggest the probable beneficial action of methylene-blue combined with quinine in the treatment of tropical malarial fevers.

The form in which the drug is to be employed is the powdered, chemically pure, medicinal methylene-blue. It is given in capsule. Owing to the scarcity of malarial fever in and about Berlin the number of cases upon which the drug has been tried is small, but the evidence presented by these cases is of such a nature as to point to this compound as a valuable addition to the list of agents that may be used in the treatment of malaria.

THE CHEMISTRY OF THE SMALL INTESTINE IN MAN.

IN their studies upon the chemical processes in the small intestine of man, MACFADYEN, NENCKI, and SIEBER[1] arrived at results that point to the error of a number of statements which are commonly made in regard to this subject.

They found that the acid chyme in passing from the stomach into the small intestine did not become alkaline, but continued of an acid reaction until it had passed through the ileo-cecal valve. As a result of this acid reaction, a decomposition of proteids by bacteria does not take place, or, at most, takes place inconstantly and to a hardly perceptible degree; and not only that, but the action of the pancreatic juice on proteids is weakened by the acid reaction of the intestinal contents. The products so easily obtained outside the body by the action of trypsin on proteids (leucin and tyrosin) were *not* to be found in the small intestine. Further, the decomposition of the food-mass prior to its passage through the ileo-cecal valve is confined to the carbohydrates. The products formed by the bacteria from the sugar in the small intestine are the two lactic acids, acetic acid, succinic acid, carbonic acid, hydrogen, and ethyl-alcohol. Their ash-analyses proved that an important function of the mucosa of the small intestine is to constantly supply alkaline carbonates for the purpose of neutralizing the acids produced by the fermentation of the sugar.

They do not consider the fermentations produced by the bacteria in the small intestine as necessary for the maintenance of our life. It is much more to be regarded as a loss that a portion of the dextrose formed by the pancreatic enzyme out of starch is not absorbed, but serves as nutriment for the parisitic bacteria of the digestive tract.

It is in the large intestine that the contents of the alimentary tract take on an alkaline reaction, and it is also here that the first evidences of putrefactive decomposition are seen. The products of decomposition of the proteids of the food as found in the large intestine are chiefly indol, skatol, phenol, lactic acid, volatile fatty acids, aromatic acids, organic bases, and ammonia; the gases are carbonic acid, hydrogen, methan, sulphuretted hydrogen, and methylmercaptan. It is easy to see that none of these products are food-stuffs.

The general surveys made of the bacterial forms present in the small intestine under normal and healthy conditions show that these vary even with slight changes in diet, or with the way in which it is

---

[1] Journal of Anatomy and Physiology, vol. xxv., 1891.

prepared. There seem to be no bacterial forms that are especially bound to and constantly to be found in the small intestine, as is seen to be the case with the oral cavity or with the colon. One characteristic mark, however, for the bacteria of the small intestine is this: that by preference, so to speak, they decompose carbohydrates and not proteids.

The proteids are decomposed in man in the large intestine, with the formation of the products that characterize putrefaction.

The case upon which these studies were made was particularly favorable for the purpose. It was a woman in whom an anus præternaturalis had been established at the extremity of the small intestine, just before it joins the cecum, so that the food-mass could be collected and studied after it had passed the entire length of the small intestine, and before it passed through the ileo-cecal valve.

During six months the patient lived with her large intestine completely cut off from the digestive process. During that time she gained in weight, and, from inspection of her urine, there was no interruption in the exchange of nitrogen as evidenced by the daily amount of urea excreted.

At the end of this time the small and large intestines were united, and the patient made a rapid recovery. The first solid stool was passed per rectum on the ninth day subsequently to operation.

REPORT OF THE NEW JERSEY STATE BOARD OF MEDICAL EXAMINERS.

We regret that we cannot publish in full the First Annual Report of the New Jersey State Board of Medical Examiners. The wretched conditions of medical or quackery practice under the old order of things are brought into sharp contrast with the ordering of such affairs as is promised and has been partly accomplished under the wiser administration of the new law that went into effect July 4, 1890.

The Board met and organized at Trenton, September 2, 1890. Since then eleven meetings of the Board have been held and 101 candidates examined. Of these, 82 were licensed to practise medicine in the State, 16 were rejected, and 3 licenses were issued in the preliminary branches. The examination papers are voted upon by the different examiners without personal knowledge of the writers. The questions are practical, and designed to test a fair degree of medical knowledge and intellectual ability. Previously to the year 1890 there was an average annual "registration" of about 300 so-called physicians. Comparing this number with the number of licentiates passed by the Board—82—it is readily seen that the new law operates by exclusion rather than by rejection. "Men who do not feel competent to pass our examinations find a convenient opening for themselves in the States where there is no medical law, *e. g.*, Massachusetts and Connecticut. Thus in Minnesota, where a similar law has been in operation since 1883, the ratio of physicians to the population has decreased over one-half during seven years—it being over 12 per cent. in 1883, and only 6 per cent. in 1890." This is a convincing argument, and must make the self-respecting physicians of Massachusetts and Connecticut blush for the condition of their local concerns. The law is perhaps the best that could at the time be passed, but can only be considered as a kind of stop-gap—the first attempt to fill the break in the levee. By its provisions the Board is a "mixed" one, five of its nine members being physicians, whilst three are "homeopaths," and one is an "eclectic."

INJUSTICE TO AMERICAN MEDICAL AUTHORS.

The question of the publication of contributions read at medical societies in other periodicals than the late-appearing Transactions or society's journal has an important aspect that is presented in a letter from our Paris correspondent contained in the current number of The Medical News. American medicine is plainly put at a disadvantage by the rules against such publication now enforced by many of our societies. It has become a matter of repeated remark that articles published only in the society Transactions, from obvious reasons are not abstracted or re-reported by European journals. The wrong even proceeds to their frequent exclusion from the *Index Medicus* and from the various annuals, epitomes, or other serial *résumés* of medical literature published over the world. It is said that the actual circulation of some of the Transactions or authorized society reports does not exceed fifty copies. Writers who have anything of importance to communicate to their professional brethren will scarcely submit longer to such an absurd restriction. The loss is a common one both to the author and to medicine generally, but to American medicine in particular.

SOCIETY PROCEEDINGS.

THE AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION.

First Annual Meeting, held at Philadelphia, September 24, 25, and 26, 1891.

(Continued from p. 497.)

SECOND DAY—SEPTEMBER 25TH.

DR. J. H. KELLOGG, of Battle Creek, Mich., read a paper entitled "Summary of My Personal Experience with Electrolysis in the Treatment of Fibroid Tumors," covering the results obtained in sixty cases. Of these, four were not treated sufficiently long to give the treatment a fair trial. Nine cases, one of which was a soft myoma, were made worse, or not much benefited. In five cases the tumor was not diminished in size, but other symptoms were considerably relieved. In eleven cases the tumor was not diminished, but the other symptoms, pain, weight, etc., entirely disappeared. In seventeen cases, the tumor was considerably diminished and the patient restored to good health. In fourteen cases the tumor disappeared entirely or became barely perceptible.

Of thirty-two interstitial tumors, the tumor was, in nine cases, diminished in size and other symptoms were removed. In six cases the tumor was not diminished in size, but the other symptoms disappeared. In nine cases the tumor was not diminished in size, but the other symptoms were in part relieved. In the fourteen cases that comprised all of the cases completely cured, both the tumor and the symptoms disappeared.

Of nine cases of sub-peritoneal growths, four were not benefited or were made worse; in one case there was slight benefit; in two, other symptoms were relieved but the tumor was not reduced in size; and in two the tumor was reduced in size and other symptoms were wholly relieved.

Of fifteen cases in which the tumor was both sub-peritoneal and interstitial, in five the treatment completely failed; one was slightly benefited; four were relieved of symptoms without reduction of the tumor; and in five there was reduction of the tumor and relief of other symptoms.

It thus appears that the cases of fibroids most benefited by electrolysis are those in which the growths are interstitial. Interstitial and sub-peritoneal growths are not benefited in the same degree. Sub-peritoneal tumors are the least susceptible of benefit. Sub-mucous fibroids are the most amenable to treatment, but of this class no well-defined cases had come under observation.

Of the fourteen cases in which no material results were accomplished, 78.7 per cent. were under forty, and 42.7 per cent. did not exceed thirty-five. In the cases of fibroid tumor in which other symptoms were cured, but in which the tumor was not diminished in size, the average age was 43.7 years. In cases in which the tumor was considerably diminished and the patient restored to good health, the average age was 40 years. In the fourteen cases in which the tumor entirely disappeared or became barely perceptible, the average age was 37.9 years.

There are, unquestionably, cases of fibroids that may be satisfactorily treated by electrolysis, and there are other cases that are fit subjects for the surgeon. There is still another class in which the patient herself or special circumstances must decide the mode of treatment that shall be adopted.

Electrolysis may be properly employed, and with expectation of success—1. In cases of small or moderate-sized tumors. 2. In interstitial growths of any size. 3. For the relief of hemorrhage and pain in any class of tumors. 4. As a means of expediting the climacteric change in any class of cases in which the application is well borne.

Cases should be subjected to surgical treatment, either removal of the appendages or hysterectomy—1. In cases of very large tumors, which have resisted the application of electrolysis for a reasonable length of time, and in which there is an uncontrolled hemorrhagic tendency. The hard multinodular fibroids are most likely to be benefited by this operation. 2. In cases of suppurating tubes, or in a seriously-diseased condition of the appendages. 3. Hysterectomy is the only remedy in cases of soft edematous myomata.

Of hysterectomy, ovariotomy, and electrolysis, it must be conceded that electrolysis is the least formidable operation. To obtain good results from electrolysis it is necessary to observe the most scrupulous care, not only in the application of the electrical current, but in the after-management of the patient. When, after applications of from 100 to 300 milliampères of current, gynecologists send patients to their homes in the street cars, in carriages, or in railway trains, distances of from two to twenty miles, it must not be a matter of surprise that now and then bad results are experienced. Patients should be sent to bed for twenty-four hours after each application of the current. Another cause of failure in the employment of electrolysis is neglect to use such other means as are known to be serviceable in the management of cases. It is not the duty of the surgeon to neglect to employ for his patient whatever remedy he believes may be beneficial, simply for the purpose of enabling him to differentiate more exactly the results of his therapeutic efforts.

The hygiene of the patient, and all measures calculated to improve the general health, must receive careful attention.

Dr. Kellogg expressed the belief that in cases of metrorrhagia the chief curative action of the current resides in its cauterizing effect upon the endometrium. Electrolysis accomplishes the same results as does curetting, not so rapidly, but more efficiently; its action penetrates the uterine tissues according to the strength and the duration of the application.

Dr. Kellogg stated it as his conviction that the current acts chiefly through its polar rather than by any subtle interpolar action. Interpolar action of the current must, necessarily, be transitory, whereas the destruction of tissue occasioned by the cauterizing action of the positive pole is tangible, and efficient and permanent in character, and as a result of which bloodvessels are plugged by coagulation, and afterward permanently closed by cicatrization, so that the nutrition of the morbid growth is materially lessened. Observation has demonstrated that a tumor, to be benefited by electrolysis, must be of such a nature and so located, as to be

susceptible to impressions upon its vascular supply, such as those described.

Dr. H. E. Hayd, of Buffalo, N. Y., reported "Two Cases of Fibroids in which Electricity Ceased to Control Hemorrhage after a Time, Although Eminently Satisfactory At First," admirably illustrating how dangerous and fatal hemorrhages may be controlled by positive galvanism after many other forms of treatment have consecutively failed. They demonstrated also the possibility of electrical satiety, a condition in which, after long and continuous electrical applications, symptoms at first relieved are provoked and aggravated. The cases also showed how after electrical applications simple measures acted favorably, when previously they had no salutary influence. Moreover they impress upon the surgeon's mind the necessity of expectant treatment in women at the menopause, and a frequent recourse to various medicaments, which may at one time fail, but after a certain period, and after the influence of other treatment, be of signal service.

Dr. Goelet stated that he could not agree with Dr. Hayd that there is such a condition as a patient becoming satiated with electricity. The cavity of the uterus is much larger than the cervical canal, and to produce a caustic action upon the endometrium the electrode must be large enough to be in contact with the entire uterine surface.

Another point is that in almost all cases of fibroid there exists endometritis, and this means catarrhal discharge, which probably prevents the action upon the diseased surface. In such a case the discharge must be gotten rid of by dilatation and drainage; in some cases it is necessary to apply the negative current to dissolve the secretions so as to permit of better contact with the diseased surface. In sensitive patients the current must not be too strong: 75 milliampères will not ordinarily cause hemorrhage. It is sometimes well to administer a mild anesthetic, preferably chloroform, for a few minutes. It is not wise too continue the application of electricity too long; if the application is made in three stages of three minutes each, or nine minutes altogether, using a mild anesthetic, a strength of from 250 to 300 milliampères can be employed; the agent must be pushed to accomplish success and not failure.

In some cases the cavity of the uterus should first be curretted so that the electrode can come in contact with the diseased surface and produce an eschar.

Dr. Goelet stated that a failure to control uterine hemorrhage by means of electricity is often dependent upon the application being too brief to produce cauterization.

Dr. Morton propounded the query, How much of the electrical action is due to the chemical products of the positive pole, and how much is due to the galvanic action pure and simple? He related a case in which persistent menorrhagia was controlled by the intra-vaginal application of a clay-ball electrode, a large growth in the groin simultaneously disappearing.

Dr. Cleaves stated that he had controlled the metrorrhagia in a case of irregular menstruation by two intra-vaginal applications of static electricity, which were given because it was not convenient to apply the galvanic current, menstruation becoming regular.

Dr. Morton added that it has been experimentally demonstrated that the negative electrode introduced into the uterus of a rabbit would cause a profuse flow of fluid from the uterus, and by reversing the poles the flow ceased. The effect is explained as one of kataphoresis—that is, the fluids pass from the anode to the kathode in a manner analogous to the occurrence of osmosis. To obtain the full effects of kataphoresis in the treatment of disease—in other words, to accumulate liquids at the negative pole—it is necessary to continue the treatment for some time.

Dr. Massey expressed a warning word against the too frequent introduction of electrodes into the uterus. The uterus should not be invaded by an electrode, or any other body that causes an equal degree of local disturbance, oftener than every five days at most; seven days constitute a better interval. He commended thoroughness of application. In causing the arrest of hemorrhage two actions are obtained from electricity: one, the constringent effect upon the uterine tissue—this is the only action obtained, unless destructive currents are used; the other consists in the destruction or cauterization of the mucous membrane, which is followed by cicatrization.

Dr. Massey emphasized the necessity for rest and rational treatment during the time of intra-uterine applications of electricity. The galvanic effect in controlling uterine hemorrhage simply induces contraction of the organ; with a sufficient current myomata can be affected similarly at the positive pole, with the employment of a platinum curette, in lessening hemorrhage.

Dr. Reading stated that in his experience the hemorrhages in question are due to a too frequent application of the current. In a case of large fibroid, extending above the umbilicus, in which menstruation was excessive both in quantity and duration, and treatment was applied two or three times a week for three months, menstruation recurred every two weeks, being quite profuse, and lasting from seven to ten days. After diminishing the number of applications to one a week, improvement immediately took place. In a second case of hemorrhage treated with a positive intra-uterine electrode two or three times a week, even after the stoppage of the hemorrhage, there was a recurrence of the hemorrhage; and upon diminishing the frequency of the applications, and substituting the negative pole for the positive, there was no further trouble.

Dr. G. Betton Massey, of Philadelphia, read a paper entitled "Electro-puncture: Its Most Useful Modifications, and Its Value in the Treatment of Fibroid Tumors," which is to appear in a subsequent number of The Medical News.

Dr. Goelet stated that he formerly performed puncture, but recently he had abandoned it, not because of any failures, but because he feared that he might have failures. He coincided with the view that longer intervals should be permitted to elapse between applications, not only in puncture, but in intra-vaginal applications. It is desirable that the effect of one treatment should subside before another is applied.

As to the technique of puncture, there is a question as to the advantages of the buried puncture, or as to the puncture by needle not insulated.

For the reason that the vaginal surface is not so very sensitive to puncture, the needle can be introduced and

scarcely be felt by the patient, unless the needle is large and much pressure is needed to cause it to enter. It is an important point that the needles should be as fine as possible. All that is necessary is to introduce the current into the structure, which can be done with a small as well as with a large needle.

Puncture may also be employed for the relief of pain, a current of from twenty to thirty milliampères being used.

Absorption can be accomplished with the positive pole just as well, if not better, than with the negative. In cases of soft myomata the positive pole is to be preferred to the negative pole.

The bad results of abdominal puncture have been due to the fact that the currents used have been too strong. The reduction of tumors by abdominal puncture can be accomplished by the employment of from ten to twenty milliampères and several needles. The needles need be no larger than exploring needles.

DR. HAYD spoke favorably of vaginal puncture for cellulitic deposits, adding that it materially assists in resolution and relieves pain, and is practically without danger. There is greater danger, however, from puncture through the abdomen; unrecognizable complications may exist: an encapsulated ovarian cyst, or a tumor, fibroid in character, which has undergone cystic degeneration, or is the seat of abscesses, may be mistaken for a large fibroid. A few enthusiastic and good men may obtain good results from good work, but much harm may be done by giving general sanction to the procedure. The intestines sometimes intervene between the tumor and the abdominal wall; there may be adhesions, or a bloodvessel may be punctured, with a resultant hematocele. In the vagina the danger is not so great as the puncture through the abdomen.

DR. VON RAITZ, of New York, read a paper on "Perimetritis and Parametritis," giving a short sketch of the pathology of both affections, and the physiological and chemical actions of the constant current. He laid stress upon such knowledge, as it does away with the empiric use of electricity and gives the profession a means of working scientifically and successfully.

In one case of parametritis and in one of perimetritis, the positive pole was placed alternately over the hypogastrium and sacrum, and the negative in the vagina; but in the case of perimetritis he introduced the electrode into the womb, and finally, as he thought nature intended evacuation of the abscess, which was peculiarly situated in the utero-vesical space, he made applications through the bladder. In the vagina he used 30 milliampères, gradually and slowly increased from about 20 milliampères; in the womb he in the same way used 30 milliampères, and in the bladder 20 milliampères.

With the negative pole in the vagina the sittings were of about one-half hour; with the electrode in the uterus and bladder of about fifteen minutes' duration. To prevent cystitis he used a solution of methylene-blue.

DR. BIGELOW expressed his disbelief in parametritis. He admitted that that which comes from septicemia does exist, but pure cellulitis or parametritis is very rare, especially where there is no salpingitis with it. When there is fluctuation in either fornix or a history of hectic, and when a circumscribed, round swelling can be distinguished, there is usually salpingo-ovaritis. Perimetritis is quite frequent and the inter-menstrual pains simulate peritonitis.

DR. GOELET stated that in parametritis and perimetritis he did not make applications to the interior of the uterus, but to the vagina; it was just these conditions that led him to propose the carbon electrode to be covered with clay, so that it could be employed without cauterizing the vaginal surface. As an additional protection he suggested that the electrode be dipped in a solution of sodium bicarbonate; but egg-albumin constitutes a much better protection. The local action of the pole takes place on the albumin instead of on the mucous surface.

Dr. Goelet considered it a good point to shift the poles, to obviate the setting up of an irritation at the point of application at one sitting. The positive pole relieves. An auxiliary to the treatment is the faradic current after the application of galvanism. It aids not only in making the patient more comfortable, but it also accelerates absorption. In some sensitive conditions the negative pole cannot be used unless the positive pole is afterward employed.

DR. MOSHER stated that he had had some favorable results from the employment of electricity in the treatment of retroversio uteri. He at first used the negative galvanic current with the ball electrode covered with cotton, but not successfully. He could not carry the ball electrode high enough to reach the part of the uterus desired, so that he devised a copper wire, in turn covered with wire, so curved that it passed high up into the uterus. By progressive modifications he was able to carry the current to the posterior wall of the uterus high up, without disturbing the ovary; by lowering the external end of the stem, he could, in many instances, replace the uterus so as to obtain not only the vital action of the current upon the muscular fibers, but a direct action on the muscular fibers of the round ligament, thereby helping to strengthen the anterior supports of the uterus. In many cases he has observed the thickened wall of the posterior part of the uterus thin out in six weeks, after four or five applications, as if the walls had been partially removed, and he has thus been able to find fibroid tumors that could not be felt at all before the treatment.

DR. NUNN stated that burning of the skin when strong currents are employed can be obviated by the interposition of a piece of wet chamois-skin between the skin and the electrode.

He maintained that electro-massage is not sufficiently attended to. A coarse current, thrown into a particular part, will set in motion the deeper muscles, occasioning an electric massage, where ordinary massage was not available.

DR. MASSEY stated that he did not think it proper to attribute all the results to the acids and alkalies present. These bodies only appear in the immediate neighborhood of the poles.

DR. WILLIAM JAMES MORTON, of New York, read a paper entitled "Metabolic Polarity and Electro-therapeutics," in which he developed certain propositions:

1. The mutual relations of the two elements and the electrolyte of an artificial voltaic cell are also the mutual relations of protoplasmic parts of living organisms during the process of living.

(*a*) The oxidation of the positive plate of the cell (the zinc) corresponds to the destructive or katabolic chemical exchanges producing waste products—urea, uric acid, kreatinin, etc.

(*b*) The hydrogen or other bases acting at the negative plate correspond to the constructive or anabolic chemical exchanges.

(*c*) The decomposition of the electrolyte corresponds to the decomposition of the animal electrolyte (blood, lymph, and other fluids).

(*d*) Oxygen and hydrogen are referred to not as the only reaction-agents, but also as types of their congeners engaged in the complex chemical exchanges of living organisms.

2. During functional rest of a given living animal area, the anabolic, constructive action or storage of energy goes on, and during functional activity the katabolic, destructive action or releasing of energy goes on, as evidenced by their opposite polarities, positivity (in the internal circuit) being the sign of functional activity, and negativity in the same circuit the sign of functional rest.

3. What was a negative (anabolic) focus during rest becomes a positive (katabolic) focus during activity.

This conception of changeable electric relation is based, among other reasons adduced by the author, upon the prior voltaic chemical relation, during which, in the complex chemism of living organisms, compounds of, for instance, hydrogen, carbon, nitrogen, or sulphur are produced at the negative element with the *absorption* of heat. Such compounds in inorganic chemistry are termed endothermic; they are more or less unstable, easily decomposable or even spontaneously decomposable or explosive. They *evolve* heat by their decomposition.

In functional activity, it is claimed that it is these unstable endothermic substances, formed by protoplasmic voltaic action during rest, which are decomposed with production of an electric current in an opposite direction ("negative oscillation").

It may be presumed that a neural impulse, efferent or afferent, initiates the explosion.

The superior power of the kathode in exciting physiological activity (including the phenomena of electrotonus) may be due to its increasing the already progressing formation of unstable or explosive material.

4. In addition to the storage-material synthetized by the animal itself, and furnishing during functional activity an electro-positive plate, the principal electro-positive fuel or oxidizable tissue is furnished by the food assimilated by the animal, which food is the result of the anabolic, storage, or constructive faculty of the plant.

5. The origin and initiation of an electric current and consequent polarity cannot be from the electro-negative plate of a voltaic cell, but the current arises from the initial chemical action at the electro-positive plate and therefore the starting-point of living chemical exchanges is in the electro-positive plate—that is to say, is katabolic, oxidizing, or destructive. At the negative plate energy is stored or rendered potential. The same is true of all the energies.

As a consequence, all metabolism, all chemical exchanges in living, animal organisms, are initially electro-positive, and if an anabolic, constructive or electro-negative focus is found by tests, it is not primary but accidental, and the result of the action of a conductively associated katabolic or oxidizing positive plate.

6. It follows that morbid metabolism, constructive or destructive, is primarily electro-positive.

7. This invariable focal positivity provides an accurate guide to medical treatment by electricity, for the morbid-tissue focus itself may be regarded in the same light as an artificial voltaic couple. The reactions following may be experimentally demonstrated upon an artificial cell.

8. Morbid metabolism may be divided into—

(*a*) Excessive chemical exchanges; (*b*) Deficient chemical exchanges.

In over-activity of the chemical exchanges—(*a*) An applied positive pole will increase the activity, *i. e.*, augment the disease; (*b*) An applied negative pole will diminish the activity, *i. e.*, palliate or cure.

In under-activity—(*a*) An applied positive pole will increase the activity, *i. e.*, palliate or cure; (*b*) An applied negative pole will diminish the activity, *i. e.*, augment the disease.

Two directions only are open for curative treatment. In over-activity the negative pole palliates or cures. In under-activity the positive pole palliates or cures.

9. If an electro-negative focus (here held to be secondary and incidental) is thought to be most desirable to be treated, the polarities indicated must be reversed.

This theory implies that vital processes are electrolytic and electro-synthetic, plus a directive tendency which is a mystery; it implies that the processes of living proceed according to electric laws, releasing by the electro-chemical action of oxidation, combustion, or katabolism, heat, mechanical, electric, and other energies, with the production of the waste-products of excretion—urea, uric acid, kreatinin, etc., and storing or rendering potential the same energies by the electro-chemical action of anabolism, with the production of formed chemical products essential, in the case of the animal, to its specialized existence—ferments, fats, glycogen, etc.

It claims as a speculative postulate, that the fundamental starting-point of both release and storage of energy, of the destruction and the construction of products, of katabolism and anabolism—of, in short, metabolism—is situated at protoplasmic foci consisting of protoplasm oxidized (or similarly attacked) and the oxidizing or attacking electrolyte of the protoplasmic voltaic couples—that the protoplasmic area attacked is therefore electro-positive, and that as a consequence of this initial action at the electro-positive area or element a secondary constructive, storing, and anabolic chemical reaction is accomplished at a protoplasmic electro-negative area or element—in short, that anabolism is secondary to and dependent upon the initial katabolism.

The theory also implies that the animal continually dies that it may live—that its constructive metamorphosis is initially dependent upon its destructive; and more concisely, as regards the constructive, that it is due to the chemical union of substances set free at the positive element by oxidation and allied actions, or there receiving a determining combining direction toward the negative element, and uniting with other substances at this negative element antecedently oxidized or not—that, in short, katabolism and anabolism are inter-

allied in an electro-chemical cycle composed of protoplasmic voltaic couples where katabolism initiates that movement which results both in waste products and in formed products, in released energies and in stored energies, in the currents of rest and of action, and which, when it ceases, is death of the part or of the whole.

It is this katabolic beginning, signalled by focal positivity, that we may hope to influence by an applied external energy and thus influence those life-processes that underlie it; and since this initial katabolic center is the source of heat, mechanical force, electric energy and of all the other phenomena of life, normal as well as morbid, we are in a position to suggest that this electric index of demonstrable and invariable electro-positive polarity is a guide which may enable the physician to thread the labyrinth of health and disease, and to apply a counter or an aiding energy in such a manner as to affect the normal or morbid phenomena by affecting their initial and underlying chemico-biological processes. As regards electric energy, it is believed that this may be accomplished in the manner outlined.

DR. NUNN stated that the theory of the chemical action should not be too exclusively adopted. Beyond it there is a great vital force or great unknown.

We talk of electricity flippantly as a fluid or force; we theorize with it; but we cannot say what it is. There is no doubt of its chemical action, but there is something besides in all cases. There is that vast field of static electricity which has little or no chemical action at all.

Magnetism more nearly resembles life-force than does electricity.

Keeping so closely to the chemical theory makes us lose sight of another great fact, that every molecule of the body is an independent being to a certain extent. Every single blood-corpuscle is in itself an independent being as far as it goes. In no other way can be explained the fact that the blood-corpuscle takes up its oxygen and nutrition and deposits them in the tissues and goes away again.

Clinically, Dr. Nunn has observed the following rule: Whenever there is tenderness upon pressure and inflammation, to use the positive, and whenever there is a swelling, as in tumors and chronic diseases, to use the negative pole.

In conclusion, DR. MORTON added that he dwelt especially upon chemical phenomena because he had to deal with what exists. The chemical life of the animal cell is an actual fact. He knew nothing about vital forces. He had never tasted, heard, or felt them; he knew nothing of entity or ideation. Vital force is just as much a mystery at the end as it is at the beginning, but the chemical affinity is a demonstrable fact—it is a thing.

DR. PLYM S. HAYES, of Chicago, read a paper entitled "Some Points in the Technique of Electrolytic Epilation," in which he maintained that, performed for therapeutic or cosmetic purposes, care should be taken to destroy the hair without leaving scars.

Theoretically, the needle to be employed in electrolytic epilation should be so constructed that it will reach the bottom of the hair-follicle and come in contact with the papilla, without doing violence to the tissues; it should be so arranged that the current will exert its electrolytic effects only at the point of contact with the papilla.

Dr. Hayes had early discovered that a blunt-pointed needle was much better than a sharp one, and a thin one than a thick one.

After a long series of experiments he came to the conclusion that steel was the only material that would give a needle of sufficient tenuity and yet having the strength and rigidity to accomplish the desired result.

The best material for the needle is found in the jeweller's "broach." This is ground to a diameter of from one two-hundreths to three two-hundredths of an inch. For one-sixteenth of an inch from the point it should be slightly thicker than the shaft; although this bulbous point is of advantage it is not an absolute necessity. The point of the needle should, as nearly as possible, represent a hemisphere. A conical point should never be used, because of the danger of piercing the walls of the hair follicle.

The temper of the jeweller's broach renders the steel exceedingly brittle; it has been found of advantage to draw the temper, in order to prevent breakage of the needle. This is best accomplished by heating in the flame of an alcohol lamp or Bunsen burner a glass tube of about one-fourth of an inch in diameter, closed at one end and containing the needle, until the tube begins to become slightly red, when it is put aside to cool. The needle will be found to be flexible, yet sufficiently rigid.

The strength of current required varies from three-fourths of a milliampère to a milliampère and one-half, and in rare instances possibly three milliampères. The strength of the current, however, must of necessity be regulated by the amount of chemical action which takes place around the needle, as well as by the amount of pain produced.

As a rule, the weaker the current, the longer the time required to destroy the tissue, including the hair-papilla. From three to six cells of the diamond carbon battery are usually sufficient.

If three or four storage cells are connected in series for tension, the current obtained from such a battery can be used.

The commercial current from an Edison plant has been successfully used. The pain produced, however, is ordinarily so great as to make its use undesirable.

The resistance in the circuit outside of the battery should be as little as possible. A battery with large cells and large elements is preferable to one with small elements.

In introducing the needle care should be taken that it follows the hair closely. The application should not last long enough to give rise to a subsequent scar.

If, by reason of the size and density of the hair and root sheaths, the needle is arrested before it has entered much beyond the neck of the follicle, the current should be permitted to pass until any adhesions that may exist are overcome.

CORRESPONDENCE.

PUBLICATION OF SOCIETY PAPERS.

To the Editor of THE MEDICAL NEWS,

SIR: If a foreigner be allowed to second an opinion advanced by an American in regard to the publication in American medical journals of papers read before

medical societies, I shall permit myself to do so on the strength of the editorial that appeared in The Medical News of September 12, 1891. It certainly seems to me to be the greatest mistake that a scientific society can commit to prevent the immediate and extensive diffusion throughout the whole medical world of the work done by its members; but this is what is constantly done in America, and what I have been sorry to notice repeatedly during my visits to your country. If American medical societies, as all the prominent European societies do, would publish their reports two or three days after each meeting, such reports would be of the greatest value to scientific investigators; but appearing as they do, rarely earlier than a few weeks after the meeting, and in too many instances a year later, these at all times important reports are not only not consulted by foreigners when they finally do appear, but, as a rule, are passed by altogether—not only to the detriment of correct bibliography, but also to the discredit of American scientific workers.

European societies, and particularly the prominent French medical societies, such as the Paris Academy of Medicine, the Society of Surgery, the Society of Hospital Physicians, the Biological Society, etc., do not only publish their reports promptly, but in order to promote a greater and more rapid diffusion of their proceedings, actually reserve to the members of the medical press a special table, where the stenographer of each journal takes his notes for the purpose of reporting immediately both the original papers and the discussion thereon, so that the very next day, for instance, after the weekly meetings of the Paris Academy of Medicine and the Paris Surgical Society, the principal medical papers appear, so that the physicians throughout the country know more or less *in extenso* what has occurred the day before at the meetings of the respective societies. Moreover, authors of original papers are allowed to communicate to the medical press extracts from their papers; and it will be readily admitted that no one is better able than the author to determine what he really intends to convey to his professional brethren.

I have often heard American physicians visiting Paris complain of the scant notice taken of American medical works in European medical literature, a fact solely due to the regrettable delay in publishing the transactions of American medical societies, which delay fully accounts for the other fact, that a subject when finally published in America *as new*, has already become an old story on this side of the great pond.

As it now is, the want of a prompt and extensive publication in the American medical press of the reports of original papers and discussion thereon which are presented at the meetings of American medical societies, has, in the minds of many European scientists, induced the mistaken idea that very little is being done in the United States in a strictly scientific sense, which thereby places the American medical profession apparently in a state of scientific inferiority as compared with other nations. Again, this apparent status of inferiority contributes to encourage the unfortunate belief that American medical diplomas are still obtainable through purchase by persons who have never gone through their regular medical studies or passed a university examination—a belief which, from my better personal knowledge, I have persistently endeavored to correct on every occasion that offered.

If I have taken the liberty to express myself so plainly, and to ask the intermediation of your estimable journal, my only apology is that, having spent several years in America, I have had ample opportunity to judge personally of the careful work and the thorough researches made by Americans in the medical domain. I have had the honor of completing my medical education and graduating at one of the prominent medical institutions of your country, and I feel all the more anxious that my European fellow-practitioners should know and be kept constantly *au courant* of the excellent work done in the United States in the medical line. I remain, my dear sir, most sincerely yours,

Arthur C. Hugenschmidt, M.D. (Univ. Pa.).
15 Rue de la Paix, Paris.

WASHINGTON DRINKING-WATER.

To the Editor of The Medical News,

Sir: Permit me to make a few statements in answer to an editorial which appeared in the issue of October 3d, and in which the drinking-water of Washington is directly blamed for the various intestinal disturbances with which many members of the recent Medical Congress were affected. Let us see how far this assertion may be regarded as just.

First, in regard to the drinking-water itself. By referring to The Medical News of April 9, 1887, you will observe that the number of bacteria in Potomac drinking-water during the summer and autumn, when not stirred up by very heavy rains, is quite low. When, however, in winter and early spring the water becomes clouded or turbid after heavy rains, the earthy matter causing the turbidity brings with it many bacteria. These disappear with the subsidence of the suspended matter. The Potomac water could not have contained more than 100 to 200 bacteria in a cubic centimeter at the time of the meeting. These bacteria are such as are constantly present in streams of any size uncontaminated by sewage. The water is therefore much safer than that of most large cities of this country.

On the other hand, the real cause of the intestinal disorders lies obviously in another direction. The continued and unparalleled hot weather in September, following upon the coolness of the summer, must have taken dealers in provisions everywhere by surprise. With an inadequate ice supply for the time being, a deterioration of the food was a matter of course. I observed several facts bearing directly upon this point during the hot wave.

It is a curious fact that the richly albuminous foods coming from distant places and passing through many hands, in which putrefactive bacteria might revel in the production of toxic products before they reach the table, foods not even sterilized by the ordinary processes of cooking (such as oysters, milk, ice-cream, etc.) should be implicitly trusted, and the uncontaminated Potomac water should receive all the blame. Again, most of the water drunk at this time must have been melted in ice, and this, I believe, is above suspicion.

If it should be shown in the future that Potomac River water is actually the cause of intestinal disturb-

ances among strangers temporarily residing here, we must assume that in this latitude the water bacteria are more irritating or toxic varieties of the same bacteria in northern streams. For this assumption there is no supporting evidence at present.

It is not my intention to imply in these brief remarks that the water-supply of Washington does not need serious attention, but the evils to be remedied do not appear to be inherent in the source of the supply, but rather in its distribution. THEOBALD SMITH.

WASHINGTON, D. C.

THE DRINKING-WATER OF WASHINGTON.

To the Editor of THE MEDICAL NEWS,

SIR: While no apology is to be offered for the unfortunate atmospheric vicissitude that attended the late meeting of the Medical Congress and the apparent resulting disturbance of function in the gastro-intestinal apparatus of many of its members, yet what is said in a leading article of your issue of October 3d cannot in justice be overlooked, since it appears as a pointed criticism.

From a medico-topographical sense Washington is not a place that one would select as conducive to the highest state of health, but it compares favorably with other towns as regards the showing of vital statistics. Indeed, the records show that New York, Boston, Charleston, Hoboken, Lowell, Mobile, Newark, New Orleans, Savannah, Brooklyn, Jersey City, and a majority of other towns, have a higher death-rate than Washington. Besides, the young men of the Columbia Athletic Club, who had their aquatic training on the Potomac, have twice carried off the first honors at the Staten Island Regatta and at Boston, where the supply of microörganisms in the drinking-water is presumably a few millions less than that of our home supply.

As a matter of fact, no particular fault is to be found with Potomac water, which stands fourth in purity on the analytical table of the water-supply of the principal cities of the United States. To be sure, I never drink it, and have not touched a drop of water for months, except for purposes of ablution and swimming; nevertheless, I did not escape a slight attack of the prevailing endemic. Many of us remember withs orrow the similar affliction that overtook visitors to the Philadelphia Centennial. I fear, however, that if the truth were told, a different cause would be given for these expressions of remorse of a guilty stomach, and that there would be revealed certain irregularities and disregard of ordinary hygienic rules, the principal of which was immoderate use of iced drinks whose chief ingredient was not *water*.

IRVING C. ROSSE.

WASHINGTON, D. C.

PURPURA HÆMORRHAGICA, OR PELIOSIS RHEUMATICA?

To the Editor of THE MEDICAL NEWS,

SIR: THE MEDICAL NEWS of August 8, 1891, contained the report of "A Fatal Case of Purpura Hæmorrhagica," by Dr. D. J. Milton Miller, of Philadelphia. It appears to me that the case is one of peliosis rheumatica, and not of purpura hæmorrhagica. Indeed, the patient was a male, and we know that peliosis rheumatica is more frequent in males; it is just the contrary in purpura hæmorrhagica, or morbus maculosus Werlhofii. The pains and swelling of the joints are special to peliosis, and not to purpura. Eichhorst says that sometimes slight pain and swelling of the joints also appear in purpura, but in peliosis pain and swelling are decided. In the latter, spots in the mucous membranes, almost constant in purpura, are generally not observed. However, Kaposi in one case found hematuria, and in another ecchymosis followed by gangrene of the mucous membrane of the palate. Edema of the eyelids is very common in peliosis, but not in purpura. Also, the large size of the spots is more in favor of the disease that Schönlein named peliosis rheumatica than of purpura hemorrhagica.

It is true that some authors do not consider peliosis as a special disease, and include it in morbus maculosus Werlhofii. Thus Dieulafoy, in his *Manuel de Pathologie Interne*, treats peliosis in the same chapter as purpura, and says, with Besnier, that in the majority of cases it is a question rather of purpura with rheumatism than of rheumatism with purpura.

Jacconet, on the contrary, treats of purpura in the chapter on scurvy, and says that it is not to be confounded with rheumatism complicated with purpura. Birch-Hirschfeld also, in his *Lebrbuch der path. Anatomie*, makes a distinction between peliosis and purpura, and so do many others. For these reasons it appears to me that the case related by Dr. Miller must be considered a case of peliosis rheumatica.

Believe me, yours truly,

DR. DONINO CROSTI.

RIO GRANDE, ZACATECAS.

The foregoing communication was presented to Dr. Miller, who has forwarded the following reply:

THE objections made by Dr. Crosti in his letter are, to my mind, hardly warranted by a careful reading of my report in THE MEDICAL NEWS of August 8, 1891, even if one believes that peliosis or purpura rheumatica is an independent affection, and not a complication, or one of the forms of ordinary purpura, as it probably is. The nosological position of any disease is, I take it, to be decided by its most prominent features, and the resemblance it bears to some general type. Looking at the nomenclature of my case from this standpoint it certainly deserves to be classed with the hemorrhagic form rather than with the rheumatic form described by Schönlein. Barring the joint-symptoms, which were more marked at the onset, as a reference to my report will show, the symptoms were all those of the severer types of the former disease. The suddenness of the onset, the size and depth of the cutaneous hemorrhages and their tendency to become gangrenous, the invasion of the mucous membranes, the hemorrhages from the kidneys, the intestines and lungs, and the rapidly fatal nature of the attack, all point to this conclusion.

That the presence of the joint-symptoms made the attack different from the ordinary types of hemorrhagic purpura was recognized in the title of the manuscript sent to you, which was "A Fatal Case of Purpura Hæmorrhagica, with Joint-Symptoms," and which, for brevity's sake, was altered to the shorter title of the printed article.

But there are no hard and fast lines distinguishing the different forms of purpura. They merge one into the other, each case being classified according to its predominating symptoms—and as the case reported by me was of a decidedly hemorrhagic type, I feel justified in calling it by the name I did. D. J. Milton Miller.

Philadelphia.

TOPICAL APPLICATION IN DIPHTHERIA.

To the Editor of The Medical News,

Sir: Having used with signal success the following formula as a topical application to the throat in the treatment of malignant diphtheria, I make this report so that a thorough test of it may be made:

℞.—Acid sulphurosi	f ℥ss.
Liquor potassæ	gtt xl.
Aquæ calcis . . .	ad f ℥iv.

Mix, filter; keep well corked, in a cool place. To be applied topically to the throat by means of a sponge, probably every hour or two.

Respectfully,

Ernst Timmermann, M.D.

Batesville, Ind.

REVIEWS.

Guy's Hospital Reports. Edited by N. Davies-Colley, M.A., M.D., and W. Hale White, M.D. Vol. xlvii., being vol. xxxii. of Third Series. 8vo., pp. xliii., 369. London: J. & A. Churchill, New Burlington Street, 1890.

The present volume maintains the high standard of the reports from Guy's, and its value is enhanced by the frontispiece, an excellent autotype reproduction of a full-length photograph of Sir William Gull. The memoir of Sir William, with which the volume opens, is sympathetically written and is well worthy of careful reading and reflection by the ambitious young physician of the day. Mr. Davies-Colley's report of cases of anthrax is a noteworthy article, and his experience with the use of ipecacuanha, internally and externally, as recommended by Dr. Muskett (*Lancet*, vol. i. p. 268, 1888) is especially interesting. Of five cases thus treated, all recovered, although three of the five had anthrax of the neck and one was in great danger. Of eight cases previously treated without ipecacuanha, two died; in both of them the neck was involved. Mr. Percy C. Evans adds a note on the action of ipecacuanha upon the bacillus anthracis. His research shows that drug to have a very decided power to destroy the bacillus when growing in broth and free from spores. On the other hand, the powder was found to have no effect whatever on the anthrax spores even after acting twenty-four hours. This failure is of no importance as regards the therapeutic action of ipecacuanha, inasmuch as anthrax bacilli never produce spores in the living tissues. Emetine was found to have no action on the bacilli, and consequently the virtue of ipecacuanha must be due to some other constituent.

Hale White contributes an interesting paper on primary malignant diseases of the liver, and James F. Goodhart an instructive lecture "chiefly concerning bruits." The pathology and prognosis of pernicious anemia also receive attention from Dr. Hale White, who insists that it is a distinctive disease, characterized by the absence of the "ordinary causes or concomitants of the anemic state." In an appendix a summary is given of all of the cases of pernicious anemia that have died in Guy's Hospital from 1855 to 1889, both years inclusive. The fact that a number of patients discharged apparently well, afterward returned and died, taken with the fact that, with one exception, Dr. White was not able to get evidence that any of the cases discharged as improved during the last ten years have remained well, shows that the prognosis is very gloomy; and that, for the future, cases should not be recorded as having recovered unless they have been followed up for some years. Two cases of genuine recovery, one his own and one Dr. Pye-Smith's, find place in Dr. White's lists. Want of space prevents allusion to the many other excellent papers in this volume.

Addresses, Papers, and Discussions in the Section of Obstetrics and Diseases of Women at the Forty-second Annual Meeting of the American Medical Association, at Washington, D.C., May 5–8, 1891.

The papers contained in this pamphlet deal with a series of important subjects, both in obstetrics and gynecology. The benefit to the reader, however, is derived not so much from the general tone of the book as from the worth of a few preëminently good articles. The reason for this lies in the want of conservatism on the part of many of the writers on gynecological subjects. The papers on this branch are, for the most part, from the pen of those who look upon gynecology as a branch of surgery, and who are inclined to throw upon those whom they designate as minor gynecologists all the responsibility of ineffectual treatment. The first article, by Dr. J. G. Carpenter, of Stanford, Ky., on "Rapid Dilatation and Curetting," loses much of the effect of the sound teaching that it contains by emphasizing the fact that failures of diagnosis and misapplied treatment, notably dilatation and curetting on the part of the practitioner, are responsible for most of the evils that call for the surgeon's treatment. He fails to admit, however, that when the diagnosis is left to the surgeon, he is as apt to stumble as the "minor gynecologist."

As usual, the subject of technique in abdominal work comes to the front in these articles. This is an unfortunate indication. There is too much attention given to technique at the sacrifice of diagnosis. The pendulum has not yet ceased swinging between surgical enthusiasm and the belief in medical treatment in gynecology.

One of the most instructive articles is by Dr. Eliza C. Minard, of Brooklyn, on "Pathological Anteflexions of the Uterus." The writer reports a case in which Dudley's operation for anteflexion had been performed with good result. The writer resorted to this treatment not because she was an advocate of the operation, but because all other forms of treatment had failed; therefore, the results are judged by her without bias. This surely strengthens the recommendations that have been put forth by the originator of the operation, and demands that this method should have future trial.

Dr. Henry C. Coe, in a paper on "Adenoma Uteri," concludes his discussion of the treatment of this affection by stating that total extirpation alone is indicated, basing this conclusion on the assertion that there is only one variety of true adenoma, and that clinically this is essentially malignant. This is a new departure in the subject that must be considered with great care before criticising, inasmuch as it comes from one perfectly qualified to originate such a doctrine.

In obstetrics there is little that is original to which reference need be made. The only article which we have space to mention is that of Dr. Henry D. Fry, of Washington. He epitomizes the accepted opinion in regard to the treatment of eclampsia by the introduction of premature labor.

NEWS ITEMS.

Evening Lectures at the Polyclinic.—A series of lectures will be delivered during the coming winter in the evening at 8 o'clock by the members of the Faculty of the Philadelphia Polyclinic and College for Graduates in Medicine, of which the following are announced: Nov. 3d, Dr. Edward Jackson, Shadow Test; Nov. 6th, Dr. B. F. Baer, A Plea for Early Diagnosis; Nov. 10th, Dr. Edward Jackson, Shadow Test; Nov. 13th, Dr. B. F. Baer, The Treatment of Retro-displacements; Nov. 17th, Dr. T. S. K. Morton, Appendicitis; Nov. 20th, Dr. R. W. Seiss, Treatment of Aural Pain.

The Mississippi Valley Medical Association held its seventeenth annual session at St. Louis, Oct. 14, 15, and 16, 1891, President Dr. C. H. Hughes, of St. Louis, in the chair. Dr. C. A. L. Reed, of Cincinnati, was elected President; Dr. E. S. McKee, of Cincinnati, reëlected Secretary; Dr. C. S. Bond, of Richmond, Ind., and Dr. J. H. Stucky, of Louisville, Vice-Presidents; Dr. Joseph Ransohoff, of Cincinnati, Chairman of the Committee of Arrangements. The next meeting is to be held in Cincinnati, October, 1892.

Pan-American Congress.—The Committee on Permanent Organization of the American Medical Association has decided to change the name of the Association to the Pan-American Congress. The convention will be held in Washington on the first Tuesday in October, 1893. Dr. William Pepper, of Philadelphia, was elected President, and Dr. Charles L. Reed, of Cincinnati, Secretary-general.

Professor Binswanger has been made Ordinary Professor of Psychiatry at Jena.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM OCTOBER 20 TO OCTOBER 26, 1891.

BIART, VICTOR, *Captain and Assistant Surgeon.*—Having been found incapacitated for active service, on account of disability incident to the service, is, by direction of the President, retired from active service, to date October 21, 1891.

VICKERY, RICHARD S., *Major and Surgeon.*—Is relieved from duty at the Army and Navy General Hospital, Hot Springs, Ark., and ordered to duty at Fort Monroe, Va.

MUNN, CURTIS E., *Major and Surgeon.*—Upon being relieved from duty at Fort Monroe, Va., is ordered to duty at Mount Vernon Barracks, Ala.

CLEARY, PETER J. A., *Major and Surgeon.*—Upon being relieved from duty at Mount Vernon Barracks, Ala., is ordered for duty at Fort McPherson, Ga.

HAPPERSETT, JOHN C. G., *Major and Surgeon.*—Upon being relieved from duty at Fort McPherson, Ga., is ordered for duty at Fort Custer, Montana.

GARDNER, EDWIN F., *Captain and Assistant Surgeon.*—Will proceed from Fort Porter, N. Y., to New York City, N. Y., for temporary duty as Attending Surgeon and Examiner of Recruits in that city.

WATERS, WILLIAM E., *Major and Surgeon.*—Upon being relieved from dury at Fort Custer, Montana, is ordered for duty at Columbus Barracks, Ohio.

JARVIS, NATHAN S, *First Lieutenant and Assistant Surgeon.*—Is relieved from duty at Fort Bayard, New Mexico, and ordered for duty at San Carlos, Arizona Territory.

JOHNSON, RICHARD W., *Captain and Assistant Surgeon.*—Upon being relieved from duty at San Carlos, Arizona Territory, is ordered for duty at Fort Bayard, New Mexico.

BROOKE, BENJAMIN, *First Lieutenant and Assistant Surgeon.*—Is relieved from duty at Fort Riley, Kansas, and ordered for duty at Fort Leavenworth, Kansas.

KEEFER, FRANK R., *First Lieutenant and Assistant Surgeon.*—Upon being relieved from duty at Fort Leavenworth, Kansas, is ordered for duty at Fort Riley, Kansas.

MIDDLETON, PASSMORE, *Major and Surgeon.*—By direction of the President, will report in person to Colonel Melville A. Cochran, Sixth Infantry, President of the Army Retiring Board at Newport Barracks, Ky., for examination by the Board.

GANDY, CHARLES M., *Captain and Assistant Surgeon.*—Is granted leave of absence for fifteen days, to take effect on final adjournment of Army Medical Board, now in session in New York City, N. Y.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment, provided that the request for reprints be noted by the author at the top of the manuscript. When necessary to elucidate the text, illustrations will be provided without cost to the author.

A CASE OF ACUTE SPINAL PARALYSIS; DEATH ON THE TWELFTH DAY; AUTOPSY SHOWING TRANSVERSE CERVICAL MYELITIS.[1]

BY WHARTON SINKLER, M.D.

With a Report of the Microscopical Examination,

BY C. W. BURR, M.D.

THE following case is of interest because, while having the clinical history both of acute poliomyelitis anterior and of Landry's paralysis, the post-mortem results show a transverse myelitis involving only the cervical portion of the cord:

The patient was a well-grown young man, eighteen years of age, of good habits, and without hereditary history of consumption or nervous disease. He was an only child, and had enjoyed excellent health until July, 1890. On the 10th of this month he went to New York for the day, and in the afternoon went to Coney Island. During the day the weather was intensely hot, but by evening there was a great change in the temperature, the thermometer falling several degrees. He suffered extremely from the cold, feeling chilled through. The next day he returned home to Philadelphia, and felt very weak. The day following he was a little feverish, and complained of general weakness and relaxation, with a sense of general numbness, especially from the hips down. He tottered a little in his walk, and had some cramp-like pains in the calves of his legs. He had a little pain in his back and head, and was drowsy and dull. There was some diarrhea. There was pain on movement, and when sitting, his legs seemed as if "asleep." The next day, July 12th, he was worse; he could not walk, his legs being too weak. In the evening of this day he found that there was some loss of power in his arms. This loss of power increased steadily, and by July 14th he was unable to move his legs at all, though still able to lift the arms and move the hands and fingers. There was temporary inability to void urine, and a little difficulty in swallowing. The bowels were moved by enemata.

On July 18th I saw the patient in consultation with Dr. Radcliffe Cheston, who gave me the foregoing history. The patient had been confined to bed for a week, and was steadily losing strength. I made the following notes of his condition: "There is slight paralysis of the left side of the face. He cannot whistle, and smiling draws the face to the right. The eyesight is good, although on the first day of his illness vision of the right eye was somewhat blurred. He can turn the head to either side; can extend it, but cannot flex it. He cannot extend either arm, but can partially adduct the arms over the chest. He can flex and extend both forearms, can pronate, but cannot supinate them; can flex, but can only partially extend the fingers. He can feebly extend the last phalanges, and can flex and extend the wrists. The grip is very feeble. He cannot raise the body or turn it to either side, owing to paralysis of the muscles of the trunk. There is complete loss of power in both legs. He cannot move a muscle, except to a slight extent the flexors and extensors of the toes. There is loss of most reflexes. The knee-jerk is entirely absent; no plantar or abdominal reflex is present, but the cremasteric and epigastric reflexes can be excited.

"Sensation is unimpaired in the upper and lower extremities, except as to compass-points. There is slight loss to these on the fingers and on the feet, the points being distinguished only when far apart. He locates well, and the pain-sense is unaffected. He says that the hands and feet feel numb and tingling, but he has no pain anywhere; on the day before, however, he had some cramp in his legs. There is no muscular tenderness or pain on pressure over the nerve-trunks. All the muscles respond to a slowly interrupted faradic current. The thigh muscles do not react as readily to the current as the other muscles. Speech is unaffected, but his voice is weak. He is much annoyed by accumulation of mucus in his throat."

On July 22d the patient had a return of difficulty in swallowing, and once or twice he had to be fed through the nasal tube. The respirations had become rapid and shallow. There was retention of urine the previous day, and the catheter had to be used, but he urinated to-day without trouble. The patient gradually lost strength, and died of respiratory paralysis July 22d, twelve days after the onset of the attack. The temperature during the attack was from 100° to 101°. The post-mortem was made forty-eight hours after death, the body having been preserved in an ice-box.

REPORT OF AUTOPSY BY DR. C. W. BURR.

The body was of average size and weight; the abomen was of a slightly greenish color. The scalp, the skullcap, and the dura mater were normal. The brain was of average size, and there was no edema or congestion. The convolutions showed no marked deviations from the common type. On cutting into the brain the gray and white matter showed well, and were of good consistency. The basal ganglia, pons, and medulla were healthy.

[1] Read at the meeting of the American Neurological Association held in Washington, D. C., September 22 to September 25, 1891.

The sciatic nerves were also healthy. The bones of the base of the skull and of the spinal canal showed no evidence of disease.

The spinal meninges were normal, and there was no excess of spinal fluid. The cord was of good color, form, and consistency throughout, except for apparent slight softening in the lower dorsal region, due probably to post-mortem change. On cross-section the gray and white matter were throughout well differentiated, as well in the dorsal as in the other regions. There was possibly some congestion at the cervical swelling.

After hardening for three months in Müller's fluid the following conditions were found: The cervical swelling still showed well the differentiation between white and gray matter, but it was crumbly and brittle, and irregular longitudinal fissures appeared in several places, notably in the posterior half (these occurred during hardening). It was misshapen in outline. The staining was normal throughout. The remainder of the cord, brain, etc., showed nothing abnormal.

Microscopical Examination.

Pieces were imbedded in celloidin and sections stained with carminate of soda and with Congo-red, and a few by Pal's method.

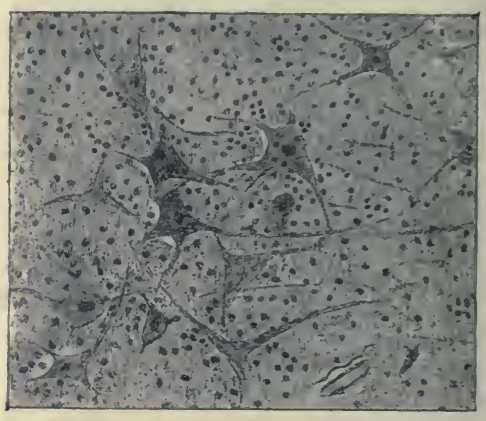
Cervical swelling. There was marked infiltration by small, round, sometimes irregularly shaped, deeply stained cells, which invaded the entire transverse section of the cord. Their distribution was not uniform, and the position of greatest intensity varied with the level of the section. In the center of the anterior gray matter on one side and posteriorly on the other were found small areas of hemorrhage and softening. There was some engorgement of capillaries. A few of the motor cells were shrunken and without processes, but most of them were normal in every respect—in form, intensity of staining, processes, appearance of protoplasm, and character of nuclei. Here and there, in irregularly-distributed spots, the nerve fibers had disappeared, but quite the larger number were still present. The pia and the posterior nerve-roots, especially the latter, were involved in the cellular infiltration. The vertical extent of the lesion was about one inch—sections from other portions of the cord, from the medulla and pons, and from the brain and sciatic nerves, showing nothing pathological.

Pathologically, the case is one of acute transverse myelitis, involving the upper part of the cervical swelling. The palsy of respiration may have been due to chemical changes sufficient to inhibit function, but not sufficient to cause material alteration of structure. The abdominal and thoracic viscera were not examined.

The accompanying illustrations made after drawings by Dr. Allen J. Smith clearly show the appearances described.

From a study of the clinical features of the case the diagnosis lies between acute multiple neuritis, acute myelitis, Landry's paralysis, and polio-myelitis anterior. Multiple neuritis can be excluded because of the absence of pain in the nerve trunks, the absence of hyperesthesia, the fact that sensibility was so little disturbed, the early loss of the reflexes, and the rapid course of the disease. Acute myelitis is accompanied with early loss of power in the sphincters, exaggerated reflexes if the disease is above the lumbar enlargement, pain in the back, contraction of the limbs, and trophic changes in the skin—symptoms all absent in this case. The symptomatology of Landry's paralysis closely resembles that

From posterior root zone.



Anterior horn, showing cellular infiltration.

of my patient, but I believe that in the typical form of acute ascending paralysis the loss of power begins in the lower extremities and spreads systematically upward. In my case, although the paralysis did begin in the legs, the loss of power in the rest of the voluntary muscles came on almost simultaneously. Still, I admit that without a post-mortem examination it would have been next to impossible to say that the case was not one of Landry's paralysis. Dr. Henry Hun read before the New York Neurological Society a valuable paper on the pathology of acute ascending paralysis.[1] The case reported by him is so strikingly like the one I have related that I will give it at some length.

[1] Journal of Nervous and Mental Disease, June, 1891.

An unmarried man of forty-five years, free from any syphilitic or rheumatic taint, was suddenly attacked, April 11, 1890, by a paresis of the legs, which in the space of four days became a complete paralysis, and then in a few days more there was loss of power in the arms and hands. He had a difficulty in speech. It was necessary to draw the urine with a catheter. The bowels were constipated. This seemed due rather to weakness of the abdominal muscles than to paralysis of the bladder and rectum. He was admitted to the Albany Hospital April 18, 1890. Ten days after the beginning of weakness in the legs Dr. Hun made the following note of the patient's condition: "Well nourished. Ptosis of right eyelid, which he says is voluntary and due to impairment of vision. This impairment of vision seems to consist of diplopia, one object being to the right of and lower than the other. Decided paralysis of lower branch of left facial nerve. Tongue protruded straight, no tremor of tongue or lips, and no muscular atrophy or fibrillary contraction. Breath very offensive and tongue covered with a white coat. He can whistle with difficulty. Speech thick and indistinct. Deglutition so difficult that he has to be fed with stomach tube. Mucus collects in trachea and patient can eject it very imperfectly. Hearing, smell, and taste are normal. Grasp of left hand *nil.* Grasp of right hand very feeble. Flexors and extensors of upper arm very feeble, but more powerful than those of forearm. Muscles of shoulder feeble, but more powerful than those of arm. Muscles of body paralyzed so that he can neither sit up nor move in bed. Absolute motor paralysis of both legs and thighs. Absence of plantar, cremasteric, umbilical, and patellar reflexes. No muscular tenderness, fibrillary contraction, or atrophy. No disturbance of sensibility, tactile (tested with pin-head and cotton), thermic, or painful impressions anywhere. No retardation of conduction of pain. Bladder and rectum inactive. Urine drawn off with catheter. Bowels moved by castor oil or by injection. Temperature and pulse normal. On April 22d, the muscles of both arms are much weaker, and those of the right arm and shoulder are weaker than those of the left, so that he can scarcely move the right arm at all. The muscles of the legs continue completely paralyzed. There is nowhere any muscular atrophy, tremor, or disturbance of any kind of sensibility, and there is no muscular tenderness. All the muscles of both legs respond decidedly and quickly to the faradic current. The difficulty of speech and respiration is so great that it does not seem possible that he can live twenty-four hours."

The patient died April 23d, five days after admission to the hospital, and twelve days after the beginning of loss of power in the legs.

"An autopsy was held eight hours after death. The spinal cord seemed normal, except that the lumbar portion seemed to be slightly edematous, and the outlines of the gray matter in this region seemed a little less clear than normal. The brain seemed normal, except that there was a somewhat increased amount of subarachnoid fluid over both parietal regions."

"A microscopical examination made by Dr. Van Gieson showed that there were a slight cerebral and spinal meningitis and infiltration of the walls of some of the veins of the spinal pia mater, and a degeneration (or neuritis) of some of the fibers of the anterior roots of the cauda equina, the nervous system in other respects being normal."

R. T. Williamson, M.D., has reported a case of acute anterior polio-myelitis in a young man, twenty-two years old, who died five weeks after the onset of the attack.[1] The case is as follows:

The patient, aged twenty-two years, consulted Dr. Pullon. When first seen he complained of a numb feeling in the right hand. The next day this had extended to the right leg and also to the left side. The right arm became paralyzed, then the left, and on the third day there was complete paralysis of both arms and legs. There was also pain in the back and slight pain in the limbs. The knee-jerks were absent; there was no anesthesia anywhere. The bladder and rectum were not affected. Rapid atrophy of the muscles of the limbs occurred after the first ten days of the illness. He remained in this paralyzed condition for about three weeks, then he began to improve. He regained slight power of movement in the toes, and there was slight return of power of movement in both arms. For financial reasons he was admitted as a patient at the Victoria Hospital, Burnley, England. The day following his admission he died very suddenly, before the hospital doctor could be called to see him. The entire duration of the disease was about five weeks. There was no anesthesia during the entire illness, and no affection of the bladder and rectum. The post-mortem examination was made by Dr. Woodyatt, the house-surgeon of the Burnley Hospital.

The spinal cord before section was normal in appearance, and so were the meninges. The cause of the sudden death was not discovered. Portions of the cervical, dorsal, and lumbar regions of the spinal cord, and pieces of the sciatic and ulnar nerves, were placed in bichromate of potash solution and sent to me for microscopical examination. To the naked eye the cord on section appeared normal, with the exception of the anterior horns of gray matter, which were of a slightly lighter color than the rest of the gray matter. The specimens were hardened in bichromate of potash solution and imbedded in celloidin. Transverse sections were cut and stained with logwood, anilin blue-black, osmic acid, Weigert's stain, etc. On microscopical examination of the spinal cord changes were found in each anterior horn of the gray matter in all three regions, cervical, dorsal, and lumbar, the most marked being those in the lumbar region, those in the dorsal, however, but slight. The changes occupied almost exactly the same position in all three regions, viz., the outer part of each anterior horn. The rest of the gray matter was not affected. In a transverse section of the lumbar region, stained with logwood, the outer half of each anterior horn of the gray matter was seen to be infiltrated by a mass of

[1] Medical Chronicle, September, 1890, page 454.

closely packed round cells. The cell-nuclei stained well with logwood. Under a low power the stained cell-nuclei were seen to be more numerous around the periphery of the patch than at the center. Also the center of the cell-infiltration had a tendency to break up and fall out of the sections.

A line drawn transversely across the cord through the central canal would roughly limit the post-anterior part of the patch of cell-infiltration, and a line drawn in the antero-posterior direction through the center of the anterior horn would give roughly the inner boundary of the patch. When examined with a high power this roundish patch of cell-infiltration was seen to be composed of small, round, nucleated cells, about the size of white blood-corpuscles, and of large, round, or oval nucleated cells. There were no real hemorrhages; only here and there two or three stray red corpuscles were seen, apparently not surrounded by any capillary wall. The perivascular sheaths of all the vessels were greatly distended with round cells. The small arteries passing from the surface of the cord to the anterior horns were dilated, and the lymph-sheaths distended with round cells. This was especially the case with the lateral median and lateral anterior arteries and their branches.

Nerve-cells. In the lumbar region, in specimens stained according to Weigert's method or with anilin blue-black, no nerve-cells could be detected in the outer half of each anterior horn—the region of the round-cell infiltration. This corresponded to the region of the antero-lateral and postero-lateral, and the central group of ganglion cells. At the inner part of each anterior horn—the region of the anterior, the internal, and the median groups—ganglion cells were seen. Some were of normal appearance, but most, especially those in the immediate neighborhood of the patch of round-cell infiltration, were shrunken and had lost their processes.

Anterior nerve-roots. Transverse section. In each nerve-bundle only a few nerve fibers were seen (stained black by Weigert's method), and instead of lying close together as in health they were widely separated from each other. Between these fibers was an infiltration of small round cells, well marked in some bundles of fibers, in some only slight; in others it was absent. Between the fibers, also, were many clear, unstained, more or less circular spaces, from which the nerve-fibers had entirely disappeared. At some places the nerve-fibers were represented by large masses of myelin (stained black).

Pieces of the anterior nerve-roots, teased out, showed the white substance of Schwann broken up into irregularly-shaped masses, or into round or oval globules. The nerve-nuclei were greatly increased in number. At some spots both white substance and axis cylinder had entirely disappeared and only the external sheath was left. The posterior nerve-roots on section presented a marked contrast to the anterior nerve-roots, appearing almost normal.

In the cervical region of the cord the changes were much the same and occurred in the same position, *i. e.*, the external part of the anterior horn; they were not so well marked, however, as in the lumbar region.

In other points the description given of the lumbar region applies to the cervical region. The pia mater was normal with the exception of very slight cell-infiltration and dilatation of the vessels of the anterior part just at the region of the anterior nerve-root.

Filum terminale. In the anterior horns the vessels were dilated. The perivascular sheaths of some of the dilated vessels contained a considerable number of round cells. This was most marked at the outer part of each horn. The nerve-cells were normal, except that at the outer part of the anterior horn one or two nerve-cells in each section could be detected, the processes of which were not quite so distinct as in health. In all four regions of the cord the changes were most marked just at the spot where the antero-lateral artery entered the gray matter, and the perivascular sheath of this artery was nearly always distended with round cells. Sections of the cord were stained for microörganisms according to Weigert's modification of Gram's method, but none were detected.

The ulnar nerve just above the wrist, both on section and in a teased specimen, showed many degenerated fibers similar to those of the anterior root. Other fibers, however, were normal.

The sciatic nerve. On transverse section many fibers had a normal appearance, but in each bundle here and there were small spaces from which the nerve-fibers had disappeared. A piece of the nerve, teased, showed some degenerated fibers. Others were normal. The smaller branches of the peripheral nerves and the medulla were not preserved for microscopical examination.

The clinical histories of the three cases detailed are in most respects alike; except that in Dr. Williamson's case the course of the disease was much longer, and there had been an attempt at retrogression of the paralysis, and there was also marked atrophy of the muscles. The post-mortem findings were all different. In Dr. Hun's case no changes could be found in the cord; in my own there was myelitis of the cervical portion of the cord, and in Dr. Williamson's there was marked degeneration of the anterior horns and some changes in the nerve-cells. It seems to me probable that had my patient lived long enough there would have been some retrogression of the paralysis, and changes in the muscles, both as to atrophy and in the electrical reactions, would have taken place.

I am inclined to believe that the condition of the cord found in my case was due to the early stage of the disease at which the patient died. Had he lived as long as did Dr. Williamson's patient, it is possible there would have been less myelitis, but degeneration in the anterior horns would have been conspicuous. I think it probable that in the early stages of poliomyelitis anterior there is a hyperemia or inflammation of the cord in the affected areas that is not confined to the anterior horns. After a few days, if the course of the disease tends toward recovery,

the general myelitis disappears and the degenerative changes in the anterior horns become pronounced. The large ganglion cells become the seat of special changes; they lose their processes, shrivel, and many disappear altogether. This seems likely from the clinical history of a case of this disease. There are at first associated with the motor paralysis certain subjective sensory disturbances in the way of formication, numbness, pain in the back and limbs, and discomfort on movement. In a few days the sensory phenomena disappear—in fact they seldom last more than a week; soon after the relief of the sensory symptoms retrogression of the paralysis takes place in those limbs that are destined to recover completely.

There have been very few autopsies in the early stages of polio-myelitis anterior, and some of those that have been reported will not bear close inspection For instance, the case reported by Charlewood Turner,[1] which is quoted by Gowers, Mary Putnam Jacobi, and others, does not seem to me to have been a case of polio-myelitis anterior:

The patient was a child two and one-half years of age. She had slipped in going down stairs, and had fallen on her back. For two weeks after this she had played about as usual. She then, one day, complained of being cold, became quite ill, and on the same day lost power in her legs. Three days later she could not use the arms. On admission to the London Hospital she was suffering from paralysis of all her limbs. She was anemic; there was fairly good muscular development. She lay on her side with her head thrown backward and the legs extended. The head could be rotated and bent backward, but could not be flexed without pain. There was no reflex action on tickling the soles of the feet, and *sensation over the legs was lost.* Sensation in the arms was perfect. The evacuations were passed involuntarily. Twelve days later the evacuations were still involuntary, but sensation was restored to the legs. The child died twenty-six days after admission and six weeks after the onset of the paralysis. At the autopsy there was found in the lumbar region of the cord hemorrhagic softening in the anterior horns, leaving a cavity.

Drummond's[2] case, the autopsy of which is the earliest on record in a case of polio-myelitis anterior, is incomplete, from the absence of clinical history:

A child, five years of age, died after an illness of six or seven hours, from respiratory paralysis. There is no mention made of loss of power in the legs or arms. At the post-mortem examination "the spinal cord in the region of the fourth and fifth cervical nerves showed undue redness in the anterior gray matter. The vessels running from the surface to the cornua were distended with blood. The microscope showed distention of capillaries and minute extravasations in the gray substance, swelling of the neuroglial elements and of the ganglion cells, which were granular with indistinct processes. The blood-vessels were distended with blood, forming a striking feature, not only in the anterior horns, but in the anterior white columns and middle and anterior portions of the posterior columns."

Drummond lays stress upon the fact that only a limited portion of the cord was affected, that is, in the region of the fourth and fifth cervical nerves, and that the inflammation extended beyond the limits of the anterior horns. The changes were found most abundantly in the anterior cornua, but they were also found in the antero-lateral white columns and in part of the posterior horns. "In fact, the anterior cornua were only the centers of inflamed areas, which reached considerably beyond their limits. It will therefore become a question whether the name proposed by Kussmaul, and adopted by the majority of writers, anterior polio-myelitis, is really an appropriate one."

Angel Money's[1] case also showed that the inflammation was not confined to the anterior horns:

The patient was a child, two years of age, that died sixteen weeks after the onset of an attack of paralysis involving both legs. The autopsy "showed changes in the lumbar enlargement, distention and thrombosis of the vessels, especially in the anterior horns. The cornua were infiltrated with leucocytes. There was absence of the large multipolar and other nerve-cells. The disease was not confined to the anterior horns, but spread forward, outward, and backward. The principal focus of mischief was certainly the center of the anterior horns."

Gowers has recently reported a case[2] of acute polio-myelitis associated with multiple neuritis. He refers to the two varieties of neuritis that are met with, the parenchymatous and the adventitious, using the latter term to designate the variety in which the connective-tissue elements were primarily affected. "Recent research," he says, "has suggested that there are two varieties of polio-myelitis, the primary affection in one being in the nerve-cells of the anterior horns, in the other in the basic substance of gray matter."

There has been an effort made of late to attribute Landry's paralysis to acute multiple neuritis, but the cases that have been cited present the features of multiple neuritis and not those of acute ascending paralysis.

The American Electro-therapeutic Association will hold its second annual session in New York during the first week of October, 1892. Dr. William James Morton, of New York, has been elected president of the Association.

A REVIEW OF SOME OF THE MORE IMPORTANT CONTRIBUTIONS TO OUR KNOWLEDGE UPON IMMUNITY AND INFECTION.

BY A. C. ABBOTT, M.D.,
FIRST ASSISTANT, DEPARTMENT OF HYGIENE, UNIVERSITY OF PENNSYLVANIA.

FOR some time past the objective point in the work of many of the most prominent investigators in the field of bacteriology has been a closer acquaintance with the phenomena of infection and immunity. These studies have been directed not only toward the methods by which these conditions may be produced in susceptible animals, but efforts have been made to determine the alterations that take place in the tissues of these animals, coincidently with the establishment of the conditions.

It is proposed in this paper to review the principal experimental work that has been contributed to the subjects of immunity and infection during the past few years and see in how far the results accord with or refute the hypotheses that have been advanced for the explanation of these conditions.

Until the year 1888 there existed four different doctrines by which the condition of acquired immunity against infection could be accounted for. The first of these theories originated with Chaveau.[1] It suggests that the immunity commonly seen to exist in animals that had passed through an attack of infection against a subsequent outbreak of the same malady, and likewise the immunity that had been produced artificially, exists by virtue of some bacterial product that has been retained in the tissues of those animals, and that by its presence prevents the development of the same organisms when they subsequently gain access to the body. This is the so-called "retention hypothesis."

On the other hand, Pasteur[2] and certain of his pupils believed that the resistance frequently afforded to the tissues by an attack of infection, or following upon vaccination against infection, was due rather to an abstraction *from* the tissues, by the organisms that were concerned in the primary attack, of a something that is necessary to the growth of the organism should it gain entrance to the body at any subsequent time. This view is known as the "exhaustion hypothesis."

In 1884, Metschnikoff[3] published the first of a series of observations upon the relation that is seen to exist between certain of the mesodermal cells of the lower animals and insoluble particles that may be present in the tissues of these animals. The outcome of these investigations was the establishment of his well-known doctrine of phagocytosis, the principle of which is that the wandering cells of the animal organism, the leucocytes, possess the property of taking up, rendering inert, and digesting microörganisms with which they may come in contact in the tissues. Metschnikoff believed that in this way immunity against infection may in many cases be explained. He believed that susceptibility to, or immunity against infection was essentially a matter between the invading bacteria on the one hand and the leucocytes of the tissues on the other. The success or failure of the leucocytes in protecting the animal against infection depends, according to this author, entirely upon the efficiency of the means possessed by them for destroying bacteria. When these means are of sufficient vigor to bring about the death of the bacteria, the tissues are victorious, but when the poisons generated by the microörganisms are virulent enough to arrest the phagocytic action of the leucocytes, then the tissues succumb and infection results.

Another explanation for the immunity as acquired by the tissues of the animal organism is that advocated by Buchner.[1] Buchner suggests that in the primary infection from which the animal may have recovered there has been produced a "reactive change" in the integral cells of the body that enables them to protect themselves against subsequent inroads of the same organism.

In 1888 there appeared from the laboratory of Flügge, in Breslau, a series of contributions that had for their object the critical review of the four hypotheses for immunity that were in existence at that time.

These experiments were of the utmost importance and gave much of the impulse to most of the work upon this obscure problem that has appeared since their publication.

The outcome of these experiments, as far as they reached, was to cast a doubt upon the accuracy of the evidence upon which the existing hypotheses were based; and indeed, from their combined results, led to the conclusion that the production of immunity follows no simple or constant course, but rather that it is dependent upon a number of factors, acting singly or together.

Bearing upon the hypothesis of retention, Sirotinin[2] found that, in so far as culture experiments were concerned, the only products of growth of the bacteria that were in any way inimical to their further development were substances that gave rise

[2] Sirotinin: Zeitschrift für Hygiene, Bd. iv., 1888.

to alterations in the reaction of the medium in which they were growing: acids or alkalies produced by the bacteria themselves. So long as the organisms were not actually dead from exposure to these substances, correction of the abnormal reaction was followed by a further development of the organisms. Sirotinin points out also that the products of the growth of bacteria, so long as they are maintained at a neutral or only very slightly alkaline reaction, serve very well as a medium upon which to cultivate again the same organism, providing the nutritive elements have not been entirely exhausted. Sirotinin remarks that, if in such a concentrated form as we find the life-products of bacteria in the medium in which they are growing, no inhibitory compounds beyond acids and alkalies are to be detected, it is hardly probable that they are produced in the tissues of the living animal and retained there to a degree sufficient to prevent the growth of bacteria that may subsequently gain entrance to these tissues, after the disappearance of the organisms concerned in the primary invasion. On the other hand, Salmon and Smith[1], Roux and Chamberland,[2] and others, had demonstrated that a sort of immunity against certain forms of infection may be afforded to susceptible animals by the injection into their tissues of the products of the growth of organisms that may themselves produce fatal results when present in the animal body. In the light of subsequent experiments, however, the interpretation of this phenomenon is not that claimed by the supporters of this hypothesis.

Upon a closer study of these nutritive products of bacteria, Hankin,[3] and Brieger and Fränkel,[4] have found that there exist in certain instances, bodies of a proteid nature (albumoses, Hankin; toxalbumins, Brieger and Fränkel) that are highly poisonous in their action upon the animal body. These substances, if isolated and introduced into the tissues of susceptible animals in sufficient quantity, give rise to structural alterations in the tissues of that animal quite analogous to those following the introduction of the living organisms by which they were produced. If, however, they at first be introduced in very small amounts and the doses slowly increased, not only will no marked systemic reaction appear, but the animal will acquire a condition of resistance to the subsequent pathogenic action of the organisms themselves. That this condition, which has the appearance of a simple tolerance, is not of this nature, has been brought out by the work of Klemperer and Klemperer shortly to be described.

As to the exhaustion hypothesis of Pasteur there is as yet no evidence whatever for its support. The work of Bitter,[1] which was undertaken with the view of determining if, in the process of artificial and natural immunity, there occurred such an exhaustion from the tissues of material necessary to the growth of bacteria that might gain entrance to them at some later date, gave only negative results. The flesh of animals in which immunity had been produced contained all the elements necessary for the growth and nutrition of the bacteria against which the animals had been protected, just as did the flesh of non-vaccinated animals.

Has the doctrine of phagocytosis, as advanced by Metschnikoff, stood the test of experimental criticism? From the evidence now in our possession this question must be answered in the negative. The first severe blow that this theory received was given by Nuttall,[2] in his work upon the antibacterial action of the animal economy. In these experiments Nuttall showed positively that the part played by the leucocytes was not at all essential to the destruction of virulent bacteria in the blood of animals, but that the serum of the blood, when quite free from cellular elements, possessed this power to a degree equal to that of the blood when all the constituent parts were present. In the blood, as such, phagocytosis could be noticed, but as a rule, the bacteria presented evidence of having undergone degenerative changes before they had been taken up by the wandering cells. Contrary to the notions in existence at the time, Traube and Gscheidlen,[3] as far back as 1874, demonstrated that considerable quantities of septic material could be injected into the circulating blood without apparently any effect upon the animal. As a result of these experiments the question that naturally presented itself was: Does the animal organism possess the power of rendering septic organisms inert, and if so, to what extent? Their further work showed that appreciable numbers of living bacteria could be injected into the circulation of warm-blooded animals without producing any noticeable effect. Particularly was this the case with dogs. If they injected into the circulation of a dog as much as 1.5 c.c. of decomposing fluid, the blood drawn from the animal after from twenty-four to forty-eight hours showed no tendency to decompose, though it was kept under observation for a long time. They believed this power of rendering living organisms

inert to be possessed by the circulating blood only to a limited degree. After the injection of much larger amounts of the putrid fluid into the blood of the animal, death usually ensued in from twenty-four to forty-eight hours. The blood drawn from the animal just before death contained the living bacteria of putrefaction, and underwent decomposition. They attribute the phenomenon to the action of the "ozonized oxygen of the corpuscles of the blood."

In 1882 Rauschenbach[1] demonstrated that in the process of coagulation, fibrin was formed; not as a specific product of the action of the colorless elements of the blood alone, but as the result of the combined action between all animal protoplasm and healthy blood-plasma, and that in the process there was always a disintegration of the leucocytes that were present. In 1884 Groth[2] demonstrated further that such a disintegration of leucocytes occurred in normal, circulating blood, though here it was not accompanied by coagulation. The results of these observations suggested the question: Does such a disintegration occur when vegetable protoplasm is introduced into the blood? For the purpose of answering this question, Grohmann, a pupil of Alexander Schmidt,[3] undertook to study the action of the circulating blood upon the vegetable protoplasm of the bacteria.

He noticed that the clotting of the blood of the horse was very much accelerated by the addition to it of certain of the lower organisms, and that at the same time the development of the organisms was checked, and in the case of the pathogenic varieties their virulence was diminished. This was particularly the case when the anthrax bacillus was employed.

Grohmann seems to have appreciated the significance of this observation, though he took no steps to study it more closely. He remarks that the system probably possesses, in the plasma of the blood, a body having disinfectant properties (*loc. cit.*, pp. 6 and 33). This work, however, was not conducted according to the more exact methods of modern bacteriological research, so that the actual demonstration of this phenomenon must be attributed to Nuttall.

Since the publication of Nuttall's work his results have received confirmation from all sides. Fodor,[4] Buchner,[1] Lubarsch,[2] Nissen,[3] Stern,[4] Prudden,[5] and others have continued in the same line, and have all made practically the same observations.

Buchner undertook a closer acquaintance with this phenomenon. His studies were directed to the active element by virtue of which the serum possessed this property. He demonstrated that the serum was robbed of this power by an exposure to a temperature of 55° C. for half an hour; that its efficacy as a germicide was not diminished by alternate freezing and thawing; that by dialysis with distilled water, or by extreme dilution with distilled water, its germicidal activity was diminished, or completely checked; but that an equal dilution could be made if sodium chloride solutions (0.6–0.7 per cent.) were substituted for the distilled water, without the antibacterial action of the serum losing any of its power. From this he concluded that the active element in this phenomenon is a living albumin, an essential constituent of which is sodium chloride, and which, when robbed of this salt, either by dialysis or dilution, becomes inert in its behavior toward bacteria. He found, moreover, that the activity of the serum alone against bacteria was greater than when the cellular elements of the blood were present. This he explains by the assumption that in the serum alone the germicidal element predominates, whereas in the blood, as such, outside of the body, it is still present, but is overbalanced by the nutrition offered by the disintegrated cellular elements, so that here the nutritive element is most conspicuous, and the destructive activity toward the bacteria is not so marked.

A closer study of the nature of this germicidal element in the body of animals has been made by Martin and Hankin,[6] who have isolated from the spleen and lymphatic glands a body—a globulin—which in solution possesses a germicidal property that corresponds in value to that seen in the normal blood-serum.

Halliburton[7] believes this body to be identical with fibrin-ferment because of the clotting that it brings about in the blood. Martin and Hankin oppose this view on the ground that fibrin-ferment possesses no germicidal properties, and further, that when this globulin is exposed to an extract made from the esophageal glands of the medical leech, it is not decomposed, as Haycraft[8] claims that fibrin-ferment is.

Similar germicidal, ferment-like globulins have been isolated from the blood by Ogata,[1] and in their studies upon tetanus Tizzani and Cattani[2] also found a body that was antagonistic to the poison produced by the organism of this disease.

Hankin believes the globulins upon which he has been working and the albuminoid bodies studied by Buchner to be identical. The most interesting, and, in the light of work that has appeared since, the most important, of Hankin's observations was not that of the power of these globulins to destroy the vitality of living organisms, but that of the relation that they bear to the poisonous, proteid products of these organisms. For example, if the poisonous products of virulent anthrax bacilli be isolated and exposed to the globulin extracted from the normal tissues, the experiments of Hankin showed a directly destructive action on the part of the bacterial products. He found that the amount of poisonous albumin that was produced by the attenuated anthrax bacilli that are employed as vaccines against the inroads of the virulent organisms was much less than that produced by organisms possessing full virulence, and he suggests that perhaps the protective influence of the inoculations that are practised by introducing into the animal the organisms that have been attenuated in virulence is due to a gradual tolerance acquired by the cells of the tissues to the action of the poison when produced in these small quantities; in the same way that a tolerance was acquired by the tissues for the venom of the rattlesnake in the experiments of Sewall,[3] and as is seen to follow the injection into the tissues of small quantities of hemialbumose, which in large quantities rapidly proves fatal.

Hankin concludes from his experiments that in certain cases the contest between infectious organisms and the animal body is conducted on the part of the invaders by means of the poisonous proteids that they produce acting in direct antagonism to the means of resistance possessed by the normal cells of the tissues. In the event of the bacteria gaining the ascendency, the normal resistance of the tissues has been destroyed by the bacterial products, whereas if infection fails to occur, then the bacteria have been killed before the poisonous albumins were produced in quantities sufficient to check the normal resistance that the tissues are seen to possess.

In their studies upon diphtheria, Brieger and Fränkel[4] isolated from among the products of growth of the organism concerned in the etiology of this disease a proteid body, a toxalbumin, as it is called by them, which possesses characteristics similar in nature to the albumoses isolated by Hankin. In his subsequent work Fränkel[1] believes himself to have demonstrated the presence of two proteids as products of growth of the bacillus of diphtheria. These bodies are opposed in their action upon susceptible animals: the one being a poisonous proteid body that is destroyed by an exposure to from 55° to 60° C. for one hour; the other, likewise a proteid body, but which is devoid of poisonous properties and is destroyed only by exposure to higher temperatures: from 65° to 70° C. This latter proteid, when introduced into the tissues of susceptible animals, possesses the power of affording immunity against diphtheria. It loses this power when heated to a temperature of 100° C. Our acquantance with these products is as yet not sufficiently intimate to discuss with profit the view held by Fränkel as to the existence of these two physiologically distinct proteids together, as products of the growth of this organism, but his method of separating them does not appear to be all that could be desired. He obtains, from the bacterial products containing the two albumins together, the one that possesses the protective power, by subjecting them to a temperature sufficiently high to completely destroy the poisonous body, but not high enough to render inert the other. That is to say, the body that he obtains after an exposure of the mixture to a temperature of from 65° to 70° C., and which is seen to afford immunity against diphtheria to guinea-pigs, he claims to be entirely distinct from the poisonous proteid believed by him to be destroyed before this temperature is reached. It does not seem impossible that, instead of the poisonous body having been destroyed by the high temperature, its physiological activity was simply modified by it, resulting in the appearance of the substance that is now without poisonous peculiarities, but which has the characteristic referred to—of affording immunity.

An epoch may be said to have been reached with the work of Behring and Kitasato[2] upon the production of immunity to tetanus. In their studies upon the blood of animals subjected to these experiments it was found that it was not only possible to render animals immune to this disease (the method has not yet been published), but that the serum of the blood of these immuned animals is seen to afford immunity when injected into the peritoneal cavity of other animals that have not been so protected; and moreover, that this serum possesses curative powers over the disease after it

had, in some cases, been in progress for a time. They found, further, that the serum of animals that had been rendered immune to tetanus, when brought in contact with the poison of tetanus, completely destroyed its poisonous properties, and that the serum from animals or from human beings who do not possess immunity to this disease has no such power.

Perhaps of greatest importance as a contribution to our knowledge upon infection and immunity is the work of Klemperer and Klemperer.[1] Their experiments bore entirely upon the nature of the infection in acute fibrinous pneumonia, and have shed much light upon some of the obscure features of that disease. They found but little difficulty in affording immunity to animals that are otherwise susceptible to the pathogenic action of the organisms concerned in the production of this disease,[2] by the introduction into their tissues of the products of growth of the organisms from which the latter had been separated. The immunity thus produced is seen in some cases to last as long as six months; again, it is seen to disappear suddenly in a way not to be explained. It was seen in one case to be hereditary.

The energy of the substance that has the power of affording immunity was seen to be very much increased by subjecting it to temperatures somewhat higher than that at which it was produced by the bacteria: 37.5° C. Klemperer and Klemperer found that if this substance was heated to a temperature of from 41° to 42° C. for three or four days, or to 60° C. for from one to two hours, intravenous injection was followed by complete immunity in from three to four days; whereas, if the unwarmed material was used, immunity did not appear until fourteen days, and then only after the employment of relatively large amounts. Moreover, when the previously-heated products are introduced into the circulation of the animal, the systemic reaction is of but short duration, but if the unwarmed substance is employed, immunity is manifest only after the appearance of considerable elevation of temperature, which lasts for a long time. In explanation of these differences, they suggest that, in the latter case, the high fever that is seen to occur in the animal may serve to substitute the warming to which the product had not previously been subjected, and which is necessary before the products of the bacteria are in a position to bring about the condition of immunity. They claim that the bacterial products employed in producing immunity in this case are not, in actuality, the immunity-affording substance, but that they are only the agents that bring about in the tissues of the animals alterations that result in the production of *another body* that protects the animal. In support of this, their argument is that several days are necessary for the production of immunity by the introduction into the animal of the bacterial products; whereas, if the blood-serum of this animal, which is now protected, be introduced into the circulation of another animal, no such delay is seen, but instead, the animal is forthwith protected. In the former case the actual protecting body must first be manufactured by the tissues; whereas, in the second it is already prepared, and is introduced as such into the second animal.

The serum of immuned animals is not only capable of rendering other animals immune, but moreover possesses curative powers when the disease is already in progress. The serum of immuned animals, when injected into the circulation of animals in which this form of infection was in progress, and in which there was a body-temperature of from 40.4° to 41° C., reduced this temperature to normal (37.5° C.) in twelve consecutive experiments during the first twenty-four hours following its employment.

Klemperer and Klemperer explain that the crisis seen in pneumonia in human beings occurs at the moment when the poisonous products, which are manufactured by the bacteria located in the lungs, are present in the circulation in amounts sufficient to call forth in the tissues the reactive change that results in the production of the antidotal substance that has the power of rendering the poisons inert.

At the time of the crisis in pneumonia the bacteria themselves are in no way affected. They remain in the lungs, and can be detected, in full vigor and virulence, in the sputum of patients a long time after the disease is cured. They have lost none of their power of producing poisonous products, and still possess their original pathogenic relations toward susceptible animals. It is only after the crisis that their poisons are neutralized by this antidotal proteid that has been eliminated by the cells of the tissues, and as this occurs the systemic manifestations gradually disappear. Klemperer and Klemperer isolated from the cultures of the diplococcus of pneumonia a proteid body that is the agent concerned in producing the tissue-changes that result in the formation of the protecting substance. They likewise isolated from the serum of immuned animals a proteid that possesses the same powers as the serum itself—of affording immunity and of curing the disease. The poisonous bacterial product they propose to call pneumotoxine; the protecting body, anti-pneumotoxine.

[1] Klemperer und Klemperer: Berliner klin. Wochenschr., 1891, Nos. 34 and 35.

[2] Animals do not, as a rule, present the pneumonic changes seen in human beings. The introduction of the diplococcus of pneumonia into their tissues results, in the case of susceptible animals, in the production of septicemia.

After obtaining these results upon the lower animals they directed their attention to human beings, and found that by the subcutaneous application of the serum of immuned animals to patients suffering from acute fibrinous pneumonia the results were in the main promising. They found that while healthy individuals and those suffering from other forms of disease presented no systemic reaction after the injection of the serum, in six cases of pneumonia in which the serum was employed there was a remarkable fall of temperature and slowing of the pulse within the first twelve hours after it was injected. In four of these cases the temperature fell to normal, but rose again after six hours. In two cases it fell to normal, and remained at that point.

It would appear from the results obtained by these two observers that immunity against this disease, and the processes concerned in its cure, were of a chemical nature, the active poisons of the organisms, the pneumotoxines, being neutralized by the tissue-products, the anti-pneumotoxines.

Results upon animals in general analogous to those of Klemperer and Klemperer have been obtained by Emmerich and Fowitzky.[1]

In the light of these experiments the hypothesis advanced by Buchner, that immunity was to be explained by reactive changes in the integral cells of the body, receives considerable support. Bearing also upon this point, the experiments of Bitter (*loc. cit.*) showed that, in the protective inoculations against anthrax, the vaccines that are employed do not disseminate themselves through the body, as is the case when the virulent organisms are introduced, but remain at the point of inoculation, and from this point, produce, by the absorption of their chemical products, the systemic changes through which the animal is protected against infection by the virulent organisms. The experiments of Emmerich and Mattei[2] upon the disease known as Schweine-rothlauf offer further support to this doctrine.

More significant, perhaps, in this connection are the results of Emmerich and Mattei,[3] and of Powlowski[4] obtained in their work upon anthrax. Emmerich and Mattei claim to have produced in the tissues of the rabbit, by the subcutaneous and intravenous injection of cultures of the streptococcus of erysipelas, a condition of resistance that enabled the animal to withstand subsequent subcutaneous inoculation with virulent anthrax bacilli. This, they claim, is not due to any antagonism between the organisms themselves, for in culture-experiments the two organisms grew well together, without any alteration in their pathogenic properties, but rather to the production of a tissue-change by which resistance to the inroads of the virulent bacilli was established. Emmerich and Mattei interpret this "reactive tissue-change" as a power acquired by the integral cells of the body, of eliminating a product that is detrimental to the pathogenic activity of the anthrax bacilli. Powlowsky (*loc. cit.*), who obtained similar results after the introduction into the animal body of cultures of the bacillus prodigiosus, of staphylococcus pyogenes aureus and of the diplococcus of pneumonia, believes them to be due to a more energetic phagocytosis that these cultures of non-pathogenic organisms had induced. They prepared, according to his views, the phagocytes for the more difficult task of rendering inert the disease-producing bacteria that were to be introduced into the tissues subsequently.

This review by no means embraces all the work that has been done upon this important subject, but the investigations that have been cited will serve to indicate the direction in which these studies have been conducted and furnish a conception of the phenomena of infection and immunity as reviewed from the present experimental standpoint.

From these experiments we may conclude:

1. That, of the hypotheses that exist for the explanation of immunity, that which assumes acquired immunity to be due to reactive changes on the part of the tissues has received the greatest support.

2. That immunity is most frequently seen to follow the introduction into the body of the products of growth of bacteria that in some way or other have been modified. This modification may be artificially produced from the products of virulent organisms and then introduced into the tissues of the animal; or the organisms themselves may be so treated that they are no longer virulent, so that when introduced into the body of the animal they eliminate poisons of a much less vigorous nature than is the case when they possess their full virulence.

3. That immunity following the introduction of bacterial products into the tissues is not the result of the permanent presence of these substances *per se* in the tissues, or to a tolerance acquired by the tissues to the poison, but is probably due to the formation in the tissues of another body that acts as an antidote to the poisonous substance.

4. That this protecting proteid that is eliminated by the cells of the tissues need not of necessity be antagonistic to the life of the organisms themselves, but in some cases must be looked upon more as an antidote to their poisonous products.

5. That in the serum of the normal circulating

[3] Ibid., 1887, p. 653.

[4] Powlowski: Virchow's Arch., Bd. 108, p. 494.

blood of many animals there exists a body that is capable, outside of the body, of rendering inert bacteria that, if introduced into the body of the animal, would prove infective.

6. That, in many instances, infection may be looked upon as a contest between the bacteria and the tissues, carried on on the part of the former by the aid of the poisonous products of their growth, and resisted by the latter through the agency of proteid bodies normally present in their integral cells.

7. That when infection occurs it may be explained either by the excess of vigor of the bacterial products over the antidotal or protective proteids eliminated by the tissues, or to some cause that has interfered with the normal activity and production of these bodies by the tissues.

8. That phagocytosis, though frequently seen, is not essential to the existence of immunity, but is more probably a secondary process; the bacteria being taken up by the leucocytes only after having been rendered inert through the normal germicidal activity of the serum of the blood and other fluids of the body.

CLINICAL MEMORANDA.

A CASE OF PUERPERAL ECLAMPSIA.

BY MORRIS B. MILLER, M.D.,
RESIDENT PHYSICIAN OF THE PENNSYLVANIA HOSPITAL, PHILADELPHIA, PA.

THE following case of puerperal eclampsia recently treated in the Pennsylvania Hospital during the service of Dr. Morris J. Lewis possesses some interest on account of the typical character of the uremia occurring after childbirth, and also in regard to the treatment instituted, which included the forcible injection of fluids, with the consequent flushing of the system of the poisonous elements retained. This seemed to contribute as much to the favorable result in the case as any other remedy used:

Ella P., a negress, twenty-three years of age, was brought to the hospital July 10th, at 11 A.M., in a semi-conscious condition, due to evident uremic poisoning. The history obtained from her friends and the physician who secured her admission was that she had fallen into labor at full term on the night previously and had been delivered of living twins at 1.40 on the morning of admission; she had seemed in good condition until 6.30 A.M., when she had the first convulsion, followed almost immediately by coma. At 7.30 A.M., between 9 and 10 A.M., and at 11.40 A.M., three subsequent convulsions occurred. She had never before borne children, but had had two miscarriages; evidences of previous kidney disease were wanting, and she is said to have enjoyed good health previously to this attack. Her friends, on close questioning, thought that she had not passed any urine for a considerable period before labor—just how long they were unable to state—but they were certain that her bowels had not moved for several days previously to her admission.

When admitted her temperature was 98⅘°; pulse 140, with high tension; respiration per minute 30, and regular; she was in a semi-comatose condition, occasionally rousing when disturbed, and giving vent to terrific yells, biting at the nurses, and expectorating thick, tenacious, blood-tinged saliva; her feet and legs were moderately edematous, her face slightly swollen, her pupils somewhat dilated, and her whole condition one of deepening uremic hebetude.

The lungs were normal, heart-sounds booming, with marked accentuation of the second sound at both the aortic and pulmonary cartilages. The uterus was well down in the pelvis and strongly contracted; there was no excessive lochial discharge; the perineum had, however, received a tear extending back nearly to the sphincter ani.

As soon as possible she was catheterized, and the contents of the bladder withdrawn, amounting to three drams of dark, smoky urine, which on boiling showed about 50 per cent. of albumin by bulk, and under the microscope presented numerous broad and narrow hyaline and blood casts, with some slightly granular, and blood in considerable quantity.

An enema containing chloral, gr. xx, and sodium bromide, gr. xxx, was immediately ordered, but was not retained, nor was a subsequent one retained that was given shortly afterward. This same dose was administered by the mouth, but the patient could not be made to swallow, so that sedative medication seemed impossible. The median cephalic vein was then opened, the bleeding being continued until the hard, rapid, tense pulse was replaced by a softer, slower one, the amount of blood taken being about nine ounces. At this juncture the use of the nasal tube suggested itself, and a soft-rubber catheter was procured and passed through the nose into the stomach, first attaching it to a small stomach-pump. The chloral and bromide were by this means forced into the stomach, together with about a quart of water. A steam-bath was immediately afterward prepared, and an endeavor was made to provoke sweating; this, however, was not accomplished until pilocarpine, gr. ⅛, was given hypodermatically, which was followed by moderate diaphoresis. The adverse criticisms recently made on the use of pilocarpine in cases of puerperal eclampsia were fully borne in mind, and the lungs were carefully watched for pulmonary hypersecretion, but as this did not occur, and as the drug acted favorably, it was again employed, always, however, in conjunction with the application of external heat.

At 12.40 P.M. the patient had a typical convulsion, lasting about one and a half minutes, commencing with a wild look in the eyes, which were rolled up and toward the left, then rapidly followed by tonic twitching of the hands, face, and legs, in the order named, and finally a clonic convulsion of the whole body. Respiration was in gasps and the lips were covered with bloody froth. Chloroform was used in this and the attacks that followed, and seemed to lessen their severity as well as shorten their duration. Croton oil was placed upon the tongue, and as it was ineffectual, repeated; elaterium was also used, but

the bowels did not move. At 4 P.M. and at 6 P.M. steam-baths with pilocarpine were given with moderate results; at 5.30 P.M. another dose of chloral and bromide was given in the same quantity by the forced injection through the nasal tube, and, as before, followed by water until the stomach was filled. Severe convulsions occurred at 4.54 P.M., 6.03 P.M., and 6.11 P.M., the one preceding the last being especially violent and lasting nearly four minutes. At 9.30 P.M. the woman was restless and seemed on the verge of another convulsion; chloral and bromide with water were repeated, and dry hot-air was used, causing more sweating than the steam-bath. During the night her condition was very serious; she was in a continuous stupor, from which it was impossible to rouse her; her pulse ran between 140 and 160; her temperature was about 103°, and her breathing was Cheyne-Stokes in character. At 3 A.M. the same treatment was repeated, and she responded by sweating profusely.

Throughout the next day, the 11th, the comatose condition continued; the pulse, however, was a little stronger and respiration was more regular. Every fourth hour the patient was given about one and a half pints of either milk or water by forced injection through the tube, to which was added cream-of-tartar water. Elaterium was given during the day, and toward evening she had three large watery stools. Sweating with dry hot-air was again resorted to, the result being satisfactory. Up to twenty-four hours after admission the urine passed amounted to only nine ounces, which contained about 40 per cent. of albumin by bulk, with blood and casts in abundance.

The note of the 12th was as follows: "Last night she had very profuse diuresis and many bowel-movements. The forced milk-and-water treatment was continued. Toward morning she seemed more conscious, and during the day has grown more rational. Had her last dose of milk at 12 noon, and since then has taken fluids naturally. Has had five watery dejections to-day, and has passed during the twenty-four hours ending at 11 A.M. about eighty ounces of urine (estimated). At 8 P.M., temperature 99⅘°, pulse 98, respiration 20; is perfectly conscious, but very irritable and in bad temper."

Convalescence was satisfactory; all edema disappeared within two or three days; the anemia, which was at first marked, rapidly improved with iron, and the albumin in the urine gradually diminished, except during an evacuation lasting four days, which was marked by headache and slight nausea, until on her discharge, August 3d, there was only a faint trace. An examination of the urine made August 1st gave the following result: Sp. gr. 1014, feebly acid, clear and limpid, faint trace of albumin; very few epithelial and pale hyaline casts, some slightly granular; no blood.

The result in this case will obviously point to the advantages in cases that cannot or will not swallow of administering by tube medicines and fluids in quantity. The ease of administration by means of a large, soft catheter attached to an ordinary syringe or funnel would place the method, which seems to commend itself by its apparent rationality, within the reach of all practitioners.

I am indebted to Dr. Lewis for his kind permission to publish this report.

CASE OF DOUBLE CLUB-FOOT, DOUBLE CLUB-HAND AND MULTIPLE DEFORMITIES.[1]

REPORTED BY WM. E. WIRT, A.M., M.D., PH.D.,
LECTURER ON ORTHOPEDIC SURGERY IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF WOOSTER, CLEVELAND, OHIO; LATE HOUSE-SURGEON, HOSPITAL FOR RUPTURED AND CRIPPLED, NEW YORK CITY.

I SEE by the reports of the transactions of the New York Academy of Medicine, that Dr. Gibney has reported a case similar to mine—one that was under treatment at the Hospital for Ruptured and Crippled, New York City, while I was house-surgeon of that institution.

The case I report is of even a more severe grade of deformity than the one reported by Dr. Gibney.

The child—a boy—was born in August, 1890, and was brought to my clinic, March 17, 1891, being then seven months of age. He presented a condition of double club-foot, double club-hand, imperfect development, and imperfect action of both ankles, knees, hips, shoulders, elbows, and wrists. In the hands there were contractures of all the fingers—so that in this child there was not a perfect-acting joint in either the upper or lower extremities except in the phalanges of the feet. The feet were in extreme equino-varus. The knee-joints and patellæ were rudimentary and the latter displaced externally. The ends of the bones were smaller than they should be and were irregular. The legs were held extended and could only be flexed through an angle of 30 degrees; the latter part of this flexion caused a crackling noise distinctly audible. The ligaments were lax, permitting nearly as much lateral motion as flexion. There was some knock-knee present. The thighs were held flexed and rotated outward. By force they could be flexed to 110 degrees and extended to 165 degrees. Rotation was limited to one-half the normal arc. Abduction was permitted to but a small extent; adduction was somewhat greater. The obstruction to motion in the lower extremities seemed bony and ligamentous and not muscular or tendinous. The right limb was shorter than the left and on the right side the trochanter major was three-fourths of an inch above Nélaton's line. There was evidently a congenital dislocation of the hip on the right side. At the shoulder and elbows the condition was very similar to that at the hips and knees, with the difference that there was more motion permitted in the upper extremities and the obstruction was more of a muscular character and less bony. The pectoral muscles were strongly contracted. There was marked double club-hand, with imperfectly developed wrists. The hands and fingers were flexed with adduction at the wrists. The flexion in the fingers was due to contracture of the palmar fascia.

We have very little to account for this condition of the child. The mother and friends state that during the fourth month of pregnancy she had a very severe fright caused by a disturbance on the street in front of her home during the middle of the night. She also states that the child was much more quiet *in utero* than her other children were. Her relatives are healthy and none are deformed. She has one other child that is perfectly healthy. The presentation at birth was the breech; the

[1] Read at the meeting of the American Orthopedic Association, in Washington, D. C., September, 1891.

labor was tedious and there was suspended animation of the infant. The head was large, unsymmetrical, and had a depression on one side. The child was very much emaciated and seemed in great pain for four months (thought to be in the head by the parents and attending physician), during which time it was very irritable. Even washing the feet or trimming the nails caused it to cry lustily. From the fourth to the seventh month the child picked up very much, but at seven months, though moderately plump, it had a very markedly undeveloped muscular system. It was unable to sit up unsupported, though there was some voluntary motion of the trunk. In the extremities the power seemed limited to a slight motion of the toes.

Recently I visited this patient and found much improvement. The child is able to sit up and endeavors to play, voluntarily moving its lower extremities at the hip, and the upper extremities in slight degree at each joint. At the knees there is a gain of 30 degrees of flexion; at the thighs there is a gain of 10 degrees of extension and 15 degrees of flexion. In the upper extremities there is the same proportionate gain.

The intelligence of the infant, though below par, has improved, and it is now, at thirteen months of age, about as bright as a baby of seven months.

The feet and hands are about in the same condition as on the first examination, the mother in the meantime not permitting any treatment.

The sensitiveness and irritation in the extremities have very much decreased, so that washing and handling the feet seem to cause very little annoyance. From being extremely emaciated at birth the child has grown to be quite plump. The head measures 18¾ inches in circumference, and is narrow across the forehead relatively to the occipital portion, which is broad.

FIBRO-MYXOMA OF THE NASO-PHARYNX.

BY J. F. BINNIE, M.A., M.B., C.M.,
SURGEON TO THE EAST SIDE FREE DISPENSARY, KANSAS CITY, MO.

WM. M., eleven years of age, of Brunswick, Mo., was brought to me on May 14, 1890, by my friends Dr. Thompson and Dr. Edwards. Dr. Edwards had seen the patient a year previously, and found that there was a tumor in the naso-pharynx, but how long it had been there could not be made out. He removed the growth with forceps, and found it to be irregularly fimbriated in shape and about two inches long. The tumor reappeared immediately and has continued to increase in size, at first being visible from the nostril, but, as it grew, gradually moving back toward the pharynx.

When brought to me the patient was emaciated and very nervous. Respiration and phonation were both impeded. On examination I found a large tumor occupying the pharynx and pushing the soft palate forward and upward. The tumor was smooth and of a pale-red color, and somewhat hard on palpation.

Chloroform having been administered, a Bellocq's canula was introduced through the nose, and by this means a loop of wire was placed in the pharynx, the free extremities of the wire being brought out through the right nostril. The loop was then guided by the finger over the tumor till it grasped the pedicle, and the wire was then threaded on a snare écraseur (Jarvis's). By this means the pedicle was very slowly divided and the tumor removed through the mouth. During the operation respiration was so much impeded that intubation with a large gum-elastic catheter was practised and removed all difficulties.

The tumor was egg-shaped and measured 2½ x 1¾ x 1¼ inches.

The pedicle was three-quarters of an inch in thickness. The cut surface of the tumor was smooth and tough. It arose from the point where the nasal mucous membrane merges into the post-nasal.

Microscopic examination proved the growth to be a fibro-myxoma.

Since the operation I have not had an opportunity to see the patient, but Dr. Edwards writes me that his health has improved marvellously, and that he has become quite stout and lusty, and has lost his exceeding nervousness.

Twice since this large tumor was removed Dr. Edwards has tried to remove small tumors from the right inferior turbinated bone, but each time has only succeeded in removing parts of them. Now, however, on my advice, he proposes to remove the turbinated bone itself.

I have examined the portions of tumor that Dr. Edwards removed and find that they also are fibro-myxomata.

The literature on this subject is exceedingly scanty. Dr. Bosworth writes that he has only seen *four* cases, but has collected a few others. Sir M. Mackenzie has notes of only *seven* cases, although he states that he has seen two or three others.

The present case is interesting because, so far as I know, no case has been reported in such a young subject. Since writing the foregoing I have, in conjunction with Dr. Hal. Foster, seen another example of this neopathy, in an adult, arising from the upper part of the posterior edge of the nasal septum.

On June 10, 1891, the patient was again brought to me. During the past year he has constantly gained strength, and is now an uncommonly sturdy youth. Since the large tumor was removed there has been recurrence, and parts of tumors have on several occasions been removed by Dr. Edwards with the Jarvis snare.

On examination the right nostril was found to be completely obstructed, and far back in this nostril a grayish mass was seen presenting, which became more prominent during the act of deglutition. From the mouth nothing could be seen on non-instrumental examination.

An attempt to remove the tumor by means of a Jarvis snare having failed, chloroform was administered and the patient's head brought over the end of the table. The finger in the naso-pharynx showed that cavity to be almost filled with a dense, slightly movable mass of uncertain origin. By means of a Volkmann's sharp spoon, introduced through the mouth, guided by the index finger of the left hand, the mass was with considerable difficulty removed.

As the tumor was being removed the origin was found to be about the level of the lower turbinated bone, near the junction of the nose and pharynx. The nasal sep-

tum was markedly deviated posteriorly. On careful examination by the finger no more growths could be discovered. Bleeding was, of course, considerable and plugging was resorted to.

On the tumor being removed, there remained a grayish surface about the size of a nickel. This was the part seen from the nose, and evidently was the point at which Dr. Edwards had removed part of the tumor with the Jarvis snare.

As a whole, the tumor was like a bag of mucous membrane enclosing three tumors each about the size of a marble, the mouth of the bag being the point of attachment to the naso-pharnyx. The shape of the growth was very irregular, and its longest diameters measured 2¼ x 1¼ x ¾ inches.

A CASE OF PLEURISY WITH EFFUSION.

By SAMUEL BELL, M.D.,
PROFESSOR OF PHYSIOLOGY AND DISEASES OF THE CHEST IN MICHIGAN COLLEGE OF MEDICINE OF DETROIT.

Annie H., aged twelve years, came under the service of Professor Wyman, at the surgical clinic. After making a brief examination he referred her to the department for diseases of the chest. Upon inspection the following conditions were found: Deformity of the spinal column; lateral curvature, chiefly in the dorsal region; bulging of the ribs on the left side; prominence of the shoulder-blade on the corresponding side; the patient anemic and the respiration hurried. No distinct point of tenderness could be detected by pressure along the vertebral column. In answer to my interrogations the mother said that the child had taken cold some four or five months previously, followed by pain, cough, shortness of breath, and the curve in the back. Her temperature was 101°, the pulse 90, the respiration 24. As the mother stated, although the child had been under medical treatment there had been no amelioration in her symptoms or improvement in her condition. Upon a correct diagnosis depends successful treatment, and this case was not an exception to the general law. The diagnosis resolved itself into a differentiation between subacute pleurisy with effusion and lateral curvature of the spinal column. It was evident that the latter had been the diagnosis, and that the girl had been treated accordingly. Submitting the little patient to a careful physical examination the following features in the case were brought out: The normal respiratory murmur over the affected side was almost inaudible and entirely absent over the base of the lung on the left side. No friction-sounds could be heard at this stage of the disease on account of the amount of fluid-accumulation. Upon percussion the normal pulmonary resonance, even in a modified form, could not be elicited. A flat sound was heard over a greater area than is circumscribed by the heart and lungs, and this was exaggerated or modified according to the position of the patient. Vocal fremitus was absent over the affected side. In accordance with the facts, a diagnosis of subacute pleurisy with effusion was made. The marked deformity, especially posteriorly, was very similar to that found in lateral curvature. The chief symptoms were cough, shortness of breath, loss of appetite and flesh, and continual rise in temperature. The treatment consisted in strapping the chest with long adhesive strips, encircling the chest, in order to keep the side as quiet as possible. This, together with a careful general tonic treatment, brought the little sufferer back to the normal state of health.

It is the large amount of serous effusion which, containing more or less cellular elements, distinguishes subacute from the acute variety of pleurisy. In order to prevent cell-proliferation and a large amount of serous effusion, the affected side should be kept as quiet as possible, thus preventing the distended pleura from frictional irritation. In the first and second stages quiet, if properly carried out, will be found a very important adjunct to internal treatment. I have not had good success with severe antiphlogistic remedies directed toward the removal of the effusion. As in this case, and in a very large percentage of such cases, the patient will be anemic, and assimilation and absorption, which play a very important part in the removal of effusions, will not be up to par. Consequently, in order that the natural absorbents of the system shall carry away the abnormal accumulation, the whole system must be built up with tonics and reconstructive treatment. As in the case in question, a careful selection, appropriate to the peculiar condition and idiosyncrasy, will yield good results.

DISLOCATION OF RADIUS BACKWARD; REDUCTION AFTER EIGHT WEEKS.

By A. H. FRASER, M.D.,
LICENTIATE ROYAL COLLEGE OF SURGEONS, EDINBURGH, OF HARPER, KANSAS.

Cases in which a backward dislocation of the radius has been successfully treated after a period of eight weeks has elapsed since the original injury are of sufficient rarity to justify the publication of the following notes:

A. B., a tall, well-grown girl, aged twelve years, was thrown from a pony. She fell on her elbow and complained of great pain. The family physician was sent for, but failed to discover any special injury to the joint; he put on a bandage, keeping the arm extended. At the end of four weeks, there being no improvement, the arm was again examined, and pronounced to be "all right;" but, as there was no movement in the joint, and considerable deformity at the end of eight weeks, the child was brought to Dr. W. G. Muir, of Harper, who asked me to see the case in consultation with him.

On examination it was discovered that the arm was fixedly extended, with the hand in a position midway between pronation and supination, without power to complete either movement. On the inner side of the joint there was a lump of callus, the result of an oblique fracture of the ulna just below the coronoid process, and the head of the radius was dislocated backward and outward. The elbow-joint was quite immovable, the arm being moved entirely from the shoulder.

We decided to attempt reduction. The mother of the child, having consulted some local practitioners, who informed her that it would be useless, or worse, to do anything, was somewhat averse to this course, but the father, on being assured that the arm would, at all events, not be made any worse, consented to our trying.

The girl being placed fully under the influence of chloroform, forcible extension and rotation of the arm outward

was made by me, while Dr. Muir with his thumbs pressed firmly downward and inward on the head of the bone. After considerable difficulty our efforts were rewarded by the head of the bone slipping into its place. A long, straight posterior splint was applied for a week, when she returned for treatment. This consisted in passive movement in the joint, and the application of an electric current to the muscles. At the date of writing, ten days after the beginning of actual treatment, the girl can pronate and supinate her hand perfectly, and flexion has been established to an angle of 45 degrees.

Such a result ought to encourage surgeons to at least attempt reduction of luxations of the elbow, even after two months have elapsed. In this case there is every prospect of getting a most useful arm.

THE LOOFAH AS AN ASEPTIC SCRUBBING-BRUSH.

BY JOHN B. ROBERTS, M.D.,
PROFESSOR OF SURGERY IN THE WOMAN'S MEDICAL COLLEGE OF PHILADELPHIA.

THE desire of surgeons to obtain a clean brush for scrubbing the skin before operations, in order to remove accumulations of epithelium and bacteria, makes a cheap article a desideratum.

I think that small pieces of the Egyptian loofah, which is found in all drug-stores for use in the bath-room, meet the indications admirably. For a number of years I have used pieces of this material for cleansing the skin before operations. A single loofah costs about ten cents and is large enough to be cut into ten or a dozen pieces. After use these pieces may be thrown away, as the cost is rather less than a cent each.

This vegetable scrubbing-brush, as it may be called, is, of course, of no value in cleansing a surgeon's nails, because it will not enter the subungual spaces as will the bristles of a brush.

I usually carry in my operating-case three or four pieces of loofah for scrubbing patients. It comes compressed like sponges, and a piece cut off before the loofah has been soaked in fluid can be carried in a small compass in an operating-case. For hospital use pieces of loofah can be kept soaking in sublimate solution until used and then thrown away, or soaked again, as the more expensive nail-brushes are treated.

MEDICAL PROGRESS.

Myxedematoid Condition of One Half of the Body.—THOMSON (*Edinburgh Medical Journal*, September, 1891) reports the case of an infant, nineteen months old, presenting a tumid condition of the right side of the body that was noticed shortly after birth. The parents were not related, nor was there a family history of goiter or of idiocy. A maternal granduncle had been insane. The mother was neurotic and presented a cardiac lesion. A younger child, four months old, was perfectly healthy and well-formed. The little patient was born naturally at term, after a tedious labor. Within a week of birth the right side of the face and the right extremities were observed to be swollen. There was little or no subsequent increase of the swelling. There were no changes in the bones; the enlargement appeared to depend upon a thickening of the subcutaneous tissues. The hair was soft and abundant. The right ear was larger than the left and presented a translucent, waxy appearance. The neck was short; the cervical fat contained several enlarged glands. The presence of the thyroid gland could not be detected. The posterior triangle of the neck on each side contained a soft, projecting mass of fat about as large as a walnut; a similar and larger mass was situated in front of the left axilla. The intelligence was enfeebled. The child died of pneumonia, but an autopsy was not permitted.

Boric Acid in the Treatment of Furunculosis.—ALISON (*La Semaine Médicale*, August 19, 1891) has recommended the administration of boric acid, internally and externally, in the treatment of furunculosis. From twelve to fifteen grains are given in two tablets daily, for from a week to two weeks. In addition, four or five times a day, gentle friction of the furuncles and the surrounding areas is made with a warm 4 per cent. solution of boric acid. In the intervals, the parts are covered with compresses saturated with the same solution. The treatment is said to abort incipient furuncles, to cause the rapid disappearance of matured furuncles, and to check the development of a new eruption. In cases of anthrax, the treatment is said to be followed by amelioration of the general and local symptoms; pain, peripheral redness, and induration diminish; the mass softens, and the pus is afforded exit; the fever declines, the agitation and the insomnia subside, and in the majority of cases recovery results without surgical interference.

The Determination of Sex.—WILSON (*Lancet*, September 26, 1891) proposes a theory that makes sex mainly dependent upon the nutritive perfection of the ovum at the time of impregnation. He holds menstruation and ovulation as practically a single process. When impregnation occurs in anticipation of menstruation, the product of conception is likely to be a male; when impregnation takes place subsequently to menstruation, the product of conception is likely to be a female—in other words, the earlier after ovulation that impregnation takes place, the greater the probability of the product of conception being a male, and, conversely, the later that impregnation follows ovulation, the greater the probability of the product of conception being a female.

The Detection of Tubercle Bacilli in Sputum.—DAHMEN (*Münchener med. Wochenschr.*, September 22, 1891) recommends heating for fifteen minutes in a flask placed in a water-bath or steam-bath sputum suspected of containing tubercle bacilli. The albumin is thus coagulated. On cooling, the solid particles and bacteria sink to the bottom of the vessel. The supernatant fluid is decanted and the cheesy sediment is triturated in an agate mortar. From this material, cover-glass preparations are made and stained in the usual way. If the quantity of sputum is inconveniently large, water may be added and sedimentation awaited. It has been found that practically only the sediment contains the bacilli when present. The supernatant fluid may after a brief interval be poured off and the lower layer heated for fifteen minutes in the manner described.

The Medical News.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment. When necessary to elucidate the text, illustrations will be provided without cost to the author.

Address the Editor: GEO. M. GOULD, M.D.,
1004 WALNUT STREET,
PHILADELPHIA.

SATURDAY, NOVEMBER 7, 1891.

THE NECESSITY OF MEAT-INSPECTION.

THE inspection by employés of the National Government of cattle intended for exportation is a commercial regulation adopted to facilitate this branch of the export trade. It is founded upon the restrictions imposed by foreign governments in the interests of the public health. The sanitary supervision of the home supply is left entirely in the hands of the municipality. It frequently happens, as recently shown in this city, that cattle condemned by government officials as unfit for exportation, on account of a diseased or unsound condition, are slaughtered and their flesh converted into sausages or exposed for sale upon the market. The government inspection service is necessarily restricted. It has no authority to dispose of the rejected cattle or to prevent them from being slaughtered for the home market. Unless the local authorities confer such authority, even the limited advantage that might thus be gained is lost to the public. But nothing short of a rigid local inspection of cattle and of the meat before it is exposed for sale will guarantee protection to the public against a practice quite common in all our cities.

We venture to assert that no city in the United States has a complete and faultless system of inspection of the flesh of animals intended for human consumption. In Philadelphia, such a service does not exist, even in name. The Board of Health has repeatedly made efforts to secure the means necessary to carry into effect a law upon the statute books relative to the sale of diseased or unsound meat, but without success.

The public alarm recently excited by the exposure of the practice of slaughtering for home use cattle rejected by government inspectors as unfit for exportation, has had the effect of putting in motion vigorous measures to detect and punish the offenders. But the chief interest centers in the fact, so pointedly illustrated, that without a system of sanitary inspection of the food-supplies, the public are not only defrauded, but their health and lives are placed in jeopardy. It rarely happens that the purchaser can decide from the appearance of meat whether the animal from which it was taken was healthy or diseased; hence the right to demand protection from the local government.

Fresh interest is imparted to this subject by our more precise knowledge of the transmission of tuberculosis through the milk and flesh of diseased animals. We know that tuberculosis is very common among cattle, and we know further that cattle suffering from this disease are slaughtered without hindrance. It is true that, if thorough, the process of cooking will protect against infection, but the chances of this result cannot be weighed against the certainty of protection afforded by rigid inspection.

Animals should be examined immediately before being slaughtered, and again before the meat is exposed for sale. In large commercial communities, where there are innumerable private slaughter-houses, the difficulties of inspection are very great. But in great measure they could be overcome by the concentration of the business of slaughtering in public slaughter-houses or abattoirs. It is the custom in Berlin to require all fresh meat not slaughtered in the public abattoir to be subjected to official inspection before its sale is permitted. To carry out this object, a number of inspection-stations have been provided, conveniently located, and so managed as to cause no hindrance to business. The staff of inspectors consists of one hundred and sixteen persons, and these are supplemented on two days in the week by from forty to fifty meat-inspectors and veterinary surgeons. To these stations the meat must be brought for examination, both macroscopical and microscopical, and,

after such examination, it is stamped according to its condition.

An examination of the results of one year's inspection shows that very much of the meat rejected and handed over to the police contained tubercle. Trichinæ and measles were present in pork eighteen and seventy-eight times respectively, while in more than one thousand calves the meat was too watery to be fit for food. Echinococci and thread-worms were found in some of the meat, and much that was brought to the stations was detained because it had become decomposed. We fear that an inspection as rigidly conducted in any of our cities would reveal results that the public have not been accustomed to suspect.

It is a reflection upon the wisdom of our legislators that they neglect an important duty until the popular voice clamors for relief. The recent *exposé* has furnished sufficient reason why an important means of conserving the public health should not be longer neglected. It is imperative that the Board of Health should renew its efforts to have a system of food-inspection at once inaugurated. A thorough system, conducted by an adequate force of trained officers, such as that now in operation in Berlin, is what is needed in every American city. The commission of a few inexperienced inspectors, unassisted by experts accustomed to the appearances of disease and the use of instruments of precision, would be an imposition upon the intelligence and confidence of the people. Fortunately, the University of Pennsylvania has inaugurated a course of instruction intended to prepare students for this special branch of investigation, so that the time is auspicious for satisfactorily meeting a much-needed public want.

THE ACARUS SACCHARI.

THE sugar insect is of interest to the physician, as it may possibly be that the large numbers found in raw sugar would make it injurious to the health of the consumer, and moreover there is a skin disease produced by handling unrefined sugar. *Acarus sacchari* is an insect belonging to the order Arachnida (spiders). This order is further divided into the families Pedipalpi (harvest-men or daddy-longlegs, scorpions, etc.) and Acarinæ (mites, ticks, etc.). These insects are particularly interesting to the medical man and veterinarian, as some of them are poisonous to man and the lower animals, and some are parasitic. DR. HASSEL was the first to call attention to the general occurrence of *Acarus sacchari* in raw sugar sold in London. According to PROF. CAMERON (see *Journ. of the Franklin Institute* for November, 1868), they were found in a living state in no fewer than sixty-nine out of seventy-two samples. He did not detect them in a single specimen of refined sugar. In an inferior sample of raw sugar he reports finding 500 mites in 10 grains of sugar, or 100,000 to the pound.

The *Acarus* may be avoided by using only refined sugar; but, even if they were eaten, it is questionable whether they would do any harm, and they might be nourishing, but no one would care to eat disgusting-looking insects by the thousand. The disease known as grocer's itch is undoubtedly due to the presence of this mite, which works its way under the skin, and produces symptoms identical with those produced by the common itch-mite, *Sarcoptes scabei*, and the remedies would be the same for both. It would aid the physician in diagnosis to know that grocers and handlers of sugar are liable to such a disease. Raw sugar is probably not sold in large cities at the present day, so that psora, scabies, or acariasis is a rare disease among grocers, but it is probably to be found to some extent among refiners and handlers of raw sugars. These mites multiply very rapidly, and GERLACH has computed that a single female would produce 1,500,000 progeny in three months. Thus, in treatment it is necessary to find a means of riddance of that last female. A microscopic examination of minute particles of scab shows them to be alive with the old and young *Acari*. The treatment is set forth in works on skin diseases, and various parasiticides are used, such as mercuric chloride, sulphur, etc.

Three species of *Acari* are found on sheep, and the "scab" is one of the most dreaded diseases of this domestic animal. Other species are found parasitic on the cat, dog, and swine. Horses, cattle, and birds are also infested, and quite a number of genera and species of these insects are known. The "ticks" *Ixiodidæ* are a well-known plague to the traveller in the tropics, and are not uncommon in this locality. A case is reported of a child playing among the leaves in a wood near Springville, Pa., who, on her return home, complained of pain in her arm. No attention was paid to it until the next day, when a raised tumor was noticed, a small portion protruding through the skin, apparently like a splinter of wood. The child was taken to a

physician, who, after considerable pain to the child and labor to himself, extracted a species of *Ixiodes* nearly one-fourth of an inch long, of an oval form and brown mahogany color, with a metallic spot, like silver bronze, centrally situated on the dorsal region.

UNITED STATES MEDICAL PRACTITIONERS' PROTECTIVE ALLIANCE.

The report of the proceedings of the first annual meeting of the United States Medical Practitioners' Protective Alliance, held at Baltimore, June 11, 1891, just published, contains the Constitution and By-laws, and the addresses of the Founder, Dr. J. H. DeWolf, of the President, Dr. W. H. Crim, and of Dr. W. V. Wilson. The objects of the Association, as stated by the Constitution, are "to maintain organized coöperation among the practising physicians who are legally qualified to practise in their respective States and in good standing in the profession, for the purpose of protecting medical practitioners from the abuse of dispensaries, that treat many who are well able to pay; from the unjust competition caused by short-term, quick-graduating, and inferior medical colleges; to endeavor to promote the passage of just and equitable laws regulating the practice of medicine in all the States, so that the license to practise issued by any one State shall be valid in any other State; and to devise means to enhance our financial condition (and thereby our usefulness) in every honorable way, and to derive the incalculable benefits that only can be obtained by combination and unity of action."

With these principles, and especially as further amplified and exemplified by the different addresses made, every honorable physician will have the heartiest sympathy. It seems strange that such an organization has not long been formed and in working order. Centralization and coöperation are the watchwords of the day in all fields of work. But in the medical business (for business the practice of medicine is in part, and in one clear aspect) there is no united action to correct the present abuse and forefend the coming evil. It has become such a part of the routine of public thought and personal habit to consider the physician as an almsgiver of his time and talents, that there is some shock to the mind even in the thought that his life should be in part governed by the same business customs as are altogether dominant in other walks of life. The terrible evil of hospital-abuse has grown and grown, by *laissez-faire*, by sinful sentimentalism, and by the kindness and scientific enthusiasm of the physician, to such frightful proportions that it is only by the combination of self-respecting medical men that head against it may be hoped for.

Every physician should hasten to become a member of this excellently planned organization. The Corresponding Secretary is Dr. J. F. Davison, of Glendola, N. J., who, upon application, will doubtless send copies of the *Transactions* for 1891. Dr. Wilson's address upon "The Abuse of Medical Charities" should be read by all.

POISONING BY ANTIKAMNIA.

Not long ago we spoke of the tendency to the debauching of therapeutics by manufacturers; and especially of the utterly reckless use of a certain well-advertised mixture of coal-tar products, of unknown composition, and very probably dangerous. The *New York Medical Journal* of October 17th editorially comments on a fatal case of "antikamnia" poisoning reported editorially in the *American Practitioner and News* of September 12th.

For a slight headache the victim had dosed herself with twenty-four grains of "antikamnia," supposed to represent eighteen grains of acetanilide, the rest of the baleful nostrum being supposed to be sodium bicarbonate. Acute delirium, unconsciousness, and fatal coma made up the train of events. Death occurred in about ten hours from the time of ingestion of the poison. Post-mortem examination failed to reveal other cause for the death than the action of the drug or drugs.

Our contemporaries justly remark that "antikamnia" should be listed among poisonous drugs not to be non-professionally and promiscuously prescribed, and also forcibly point out that the use of powerful agents of undeclared composition is in every instance likely to lead to unfortunate, if not always fatal results. The Philadelphia County Medical Society has a provision debarring from membership those who prescribe nostrums. "Antikamnia" certainly falls within this wise prohibition.

The seducer is always culpable. The seduced may or may not be justly liable to condemnation, according as she may or may not have age, knowledge, and experience of the world. The manufacturer who, for purposes of gain, lures members of the

medical profession to the use of his secret and worthless, if not dangerous, products must be despised by every right-thinking person. But can the physician who yields to the unholy solicitation plead either tender years or ignorant innocence in excuse of his miserable fall?

It is time to speak plainly and to act courageously, or the corruption must extend until the prostitution of our art is complete and irremediable.

SOCIETY PROCEEDINGS.

THE AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION.

First Annual Meeting, held at Philadelphia, September 24, 25, and 26, 1891.

(Continued from p. 524.)

THIRD DAY—SEPTEMBER 26TH.

DR. W. F. ROBINSON, of Albany, N. Y., read a paper on "Electricity in the Treatment of Rheumatism." Therapeutically he divided cases of rheumatism into two classes: 1. Those in which only one or two joints are affected, which he always treats by means of galvanism. 2. Those in which the rheumatic poison is more extended in its action, involving joints, muscles, fascia, etc., for which he employs static electricity. The electrodes used should be large—the larger the better—and carefully made. If covered with sponge, this should be soft and free from gritty particles. In order to increase the conductivity of the skin, the sponges should be saturated with a hot solution of bicarbonate of soda. The caustic action and the electrolytic action of the electrical current are to be avoided in the treatment of rheumatism. The action of vital stimulation is to be sought; to obtain it the procedures of interruption and voltaic alternation must be adopted. Voltaic alternation is a still stronger stimulation than interruption, but it must be used with caution, for with strong currents the pain and irritation are very great. Joint-rheumatism, pure and simple, is almost powerless to withstand the direct application of the galvanic current. When the disease is more diffused and involves various tissues and organs in different parts of the body, static electricity is indicated. The general charge is rarely used alone, and static electricity is usually given by means of special electrodes in the form of sparks. The applications may be made on alternate days. The usual length of the treatment is ten minutes, for about five of which sparks are drawn, the patient during the remaining five minutes simply sitting quietly upon the platform and taking the general charge.

Dr. Robinson expressed the belief that electricity has a twofold action that meets all the indications of rheumatism: a specific action against the morbid process and a general tonic action that tends to build up the system depressed as a result of the disease.

DR. GOELET stated that the sedative effect of galvanism could best be had by currents of short duration. To make a clay electrode that can be applied agreeably to the patient, Dr. Goelet makes the clay of the consistency of putty, and so maintains it by keeping it moist. A flat pad is made by rolling it on a board as if it were dough; it is gotten into shape, and, after having a metallic plate placed on the back, is covered with a layer of absorbent cotton; then sewed up in a gauze cover. On the back is placed rubber cloth, just as in sponge-covered hand electrodes. To avoid the discomfort of a cold application the electrode may be kept on a warming-pan which consists of a flat zinc jug filled with hot water.

DR. WALLING stated that he had observed pain in the cardiac region from positive insulation, while negative insulation occasioned no discomfort. The positive causes constriction of the capillaries, thus acting on the circulation, while negative insulation does not.

PROF. EDWIN J. HOUSTON, on invitation, said that heretofore advances in the line of electro-therapeutics have been somewhat hampered by the natural tendency to regard the body as a receptive device rather than as an electric source, as it must be regarded. Chemical processes are constantly going on in it that must result in a difference of potential between the different organs. If this is true, then there must necessarily exist variations in regard to the differences in potential in the organism. Secondly, the human body necessarily displays differences of temperature; although the temperature of the body is about 100° F.. yet there are differences in the internal organs and in the generation of true thermo-electricity. These differences of temperature must also result in differences of potential, which the body normally possesses, and necessarily in febrile disturbances there would be abnormal electrical conditions to which in the future the electro-therapeutist might do well to direct his observation. Thirdly, the body presents abnormal and normal currents. There are demarcation currents, currents produced by injuries to nerves and chemical decomposition, a result of the tendency to a restoration of the normal condition. If the human body is to be regarded as an electrical source, the electrical diagnostician, as well as the electro-therapeutist, has to ascertain the following conditions of the body:

First. The condition of the human body as regards differences of potentialism.

Second. The changes of muscles following the conditions of rest and activity.

Third. The resistances of the different parts of the body.

In all these directions the most promising line of research must be in modifying and ascertaining the true resistance of the different parts of the body; if possible, to eliminate that very variable element, the resistance of the skin. When the resistance of any organ or part of an organ, or the whole body or a part of the body, and differences of potential in volts are known, proper calculations can be made.

Under what conditions may the resistance of the body be expected to vary? First, the condition of the skin as to dryness or moisture, and then the diseases of the skin; second, the temperature; and, third, whether the resistance of the body would be the same from the head to the feet as from the feet to the head; if the human body is a source and not a receptive of electricity, the body must have a resistance; and fourth and most important, the normal and abnormal condition of the body as

altering its resistance. It is well known that diseases (at least some of them) change the resistance of the body very materially.

Dr. M. A. Cleaves, of New York, read a paper on "The Use of the Galvanic Current in Articular Inflammatory Exudations," in which she reported a case of subacute articular rheumatism of the right wrist and hand in a woman who had already suffered several attacks of inflammatory rheumatism. The hand was swollen, infiltrated, and edematous. There was a decided increase of local temperature, much pain, and extensive capillary congestion. The carpal and metacarpo-phalangeal articulations were in a state of extension; muscular power and sensation were almost lost.

Stabile applications of galvanism, 10 milliampères for fifteen minutes, with the anode at the sternum and the kathode successively to the dorsal aspect of the wrist and metacarpo-phalangeal articulations, were soon followed by relief from pain, diminution of heat, and increased mobility. The treatment was given daily for one week, then at intervals of two or three days. In all there were thirteen séances.

Subsequently five applications of the faradic current were made, the secondary kathode at the sternum, the anode to the motor points and labile to arm and hand, 35 cyl., for from five to ten minutes, with the result of increasing muscular power. The ultimate improvement was decided and satisfactory.

In another case there were partial extension, pain, and loss of mobility of the right wrist and hand, as a sequel of cellulitis and blood-infection following the bite of a mosquito. The interrupted galvanic current was applied by means of a gauze-wire electrode, 3 by 4 inches, covered with absorbent cotton, placed over the spinal region of the brachial plexus and attached to the anode, the kathode being connected with a cotton-covered gauze wire, 1½ by 8 inches, placed successively over the carpal, metacarpo-phalangeal, and phalangeal articulations. The current-strength was as great as could be borne. The length of the séance was from fifteen to twenty-five minutes. There was soon increase in mobility of the affected joints, partial restoration of function, and relief from pain.

There were eleven sittings. The final result was not all that could have been desired, but was a decided improvement upon the preëxisting condition. The question naturally arises, Why should we wait until the advanced stages, attended as they are with marked thickening of the articular and peri-articular tissues, contractions of muscles, exudative matter about sheaths of tendons, greater or less impairment of movement, and deformity, in which electricity must be our chief resource, when better results can be obtained in a subacute condition, before exudative matter has become so fully organized.

There is no danger of developing more acute inflammation. On the other hand, it is necessary to excite a more active circulation in the part, with a view of removing the congested state of the capillaries and venules, so favorable to the development of fibroid growths.

Massage is a means toward the same end, but while it quickens and equalizes the circulation, it does not possess the powers of galvanism to produce chemical changes.

In adopting a definite plan of treatment, Dr. Cleaves was governed by the hypothesis that "living means nutrition, nutrition chemical action, and chemical action under proper conditions means electric current." These conditions are (*a*) a closed circuit combined with (*b*) any two different tissues, and (*c*) one acted upon, the other not.

Animal currents are proved to exist. The acted-upon tissue is an "electro-motive source." It corresponds to the zinc of a primary battery. The electrolyte is the fluid conveying the food to the cells of the acted-upon tissues.

The acted-upon tissue is always *electro-positive* to some other tissue acted upon. This hypothesis holds true of both normal and morbid nutritional processes. As regards such processes, it compels us to base our treatment upon the broad generalization that *every such process is an "electro-positive focus."*

Proliferation is an excessive chemico-nutrition, which the positive pole makes more excessive, the negative pole less excessive—that is, counteracts.

In atrophy there is a deficient chemico-nutrition, which the positive pole stimulates and restores. The negative pole, on the other hand, makes more deficient or destroys. The results, united with much that has been done heretofore, are confirmatory of the hypothesis upon which treatment was based.

In the treatment of disease, results are, after all, the main thing, even if the relation between cause and effect in the use of remedies cannot always be explained; once a scientific basis for polar action is established, much confusion will be done away with, and a decided step will have been taken toward the establishment of a rational electro-therapy.

Dr. von Raitz, of New York, read a paper on "Electricity in Ankylosis," in which he said that false ankylosis, even with some osseous union, yields to the constant current, with the assistance of massage and passive motion, provided the treatment is carried on earnestly and intelligently.

As the synovial membrane secretes an alkaline lubricating fluid, the functions of nature are to be stimulated by the application of the negative pole. Consequently the affected joint must be snugly enclosed in an electrode connected with the negative pole. Another large electrode may be placed over any indifferent part, and connected with the positive pole. With large electrodes, powerful currents can be used without causing pain or inflammation. For the larger joints, 100, even 120 milliampères, in half-hour sittings, three times per week, are generally sufficient. Much will depend upon massage, to be applied before the current, upon passive motion, upon constitutional treatment, and upon general hygienic conditions.

Dr. Charles G. Stockton, of Buffalo, read a paper on "The Use of the Gastric Electrode in Diminished Peristalsis."

The instrument employed consists of an ordinary stomach-tube, twenty-eight inches long, with two openings near the distal extremity. At the proximal extremity it is fitted with a hollow steel coupling, which, attached to three feet of the rubber tubing, makes a continuous siphon about five feet in length. With this, the stomach is emptied, and without removing the instrument from the stomach, the tube is disconnected

at the coupling, and a spiral wire, also twenty-eight inches long, is introduced into the tube and the coupling closed by a polished steel plug at the proximal extremity, a sponge electrode being applied to the back or abdomen. In this way the current is conveyed to the stomach admirably, and the electrode does not come in contact with the gastric mucous membrane, save at the fenestra on either side of the tube.

In the treatment of cases of gastric derangement it is best to restrict the diet to those substances that, upon examination of the stomach-contents, are found to be most readily digested. The current should be applied after lavage has been practised, and the faradic current is that which is usually most satisfactory, and which must be applied in sufficient strength to produce, not merely contraction of the abdominal muscles, but movements of the stomach itself.

The sittings should continue for from five to fifteen minutes, usually beginning with five-minute séances and increasing the duration until the limit of endurance is reached, as shown by an excessive secretion of mucus, a disturbance of digestion, or a feeling of lassitude or pain on the part of the patient.

Having reached this, the proper dosage can readily be estimated. The treatment must, in some instances, be continued for a prolonged time; in other cases, relief follows a few applications.

Dr. Stockton related that he had obtained greater benefit from the application of the continuous current, with occasional interruptions, than from the application of the faradic current.

Twenty-one of forty cases treated in the manner outlined showed greater or less dilatation, as demonstrated by accurate measurement. Of this number, twelve presented dilatation of an extreme degree. Some are still under treatment, but five have been discharged as cured; all have been greatly benefited and a number have improved to such a degree that absorption takes place properly and the stomach is emptied quite uniformly five or six hours after an ordinary meal.

Cases of marked gastric catarrh do best with the continuous current, the anode applied within, the kathode on the back, from eight to fifteen milliampères being generally employed.

With the current occasionally interrupted dilatation may be relieved, and, not infrequently, the catarrh also improved. In instances of atrophy of the mucous membrane, either current may be employed. The continuous current is useful here because it is more potent in stimulating the secretion of hydrochloric acid than the faradic. Occasionally an excess of hydrochloric acid interferes with the electrical treatment. This, however, is unusual and generally but temporary. As a rule, in ordinary instances the applications should be made at bedtime and the stomach left empty and at rest during the night. This plan, however, will prove impracticable when there is great excess of hydrochloric acid, for this so disturbs the empty stomach that the patient not infrequently loses sleep or wakens in the morning feeling miserably.

In nearly every case of weakened motility, electricity by direct application is of the utmost importance. The exceptional cases are those associated with malignant disease, a few rare cases associated with gastric ulcer, and some instances of general neurasthenia, in which electricity, no matter how or where applied, is resented by the patient.

DR. LAWRENCE WOLFF, of Philadelphia, read a paper on "Electricity in Diseases of the Stomach." He maintained that the application of galvanism with a view of exciting increased glandular secretion has been decidedly overrated. At no time had he been able, by chemical means, to detect an increase of hydrochloric acid in the gastric juice after the external application of the galvanic current. As internal galvanization, with a view of improving the digestive powers, could only be practised when the stomach was partially filled with water, its value, if it possessed any, would not be available. Yet Dr. Wolff had found the galvanic current useful and of the greatest value in dilating traumatic strictures of the esophagus. He reported an illustrative case in which by the daily employment of metallic bougies in conjunction with galvanic currents of from five to ten milliampères a cicatricial stricture of small caliber was satisfactorily dilated.

The electrode employed consisted of a soft copper wire, at the lower end of which was a thread for screwing on the olive-shaped bulbs, while at the other end was a clamp for the reception of the wire, which was insulated by being covered with soft rubber-tubing. A large flat electrode was applied to the epigastrium and the sound introduced into the esophagus as far as the stricture, before the connection was made; the current was then gradually permitted to pass and increased until a perceptible sensation at the situation of the external electrode was experienced by the patient. The current was again withdrawn before the removal of the sound.

Dr. Wolff stated that he had also found faradic stimulation of the muscular fibers of the stomach serviceable in atonic ectasis. Before the principal meal of the day the stomach is washed out and the patient is requested to drink about two glasses of water; the tube containing the electrode is then swallowed; the current is then turned on, first gradually, and until peristaltic contraction is apparent to the hands applied to the parietes or to the eyes. The external electrode is usually a large and broad sponge, and is generally applied to the epigastric region; the internal electrode must be immersed in the water contained in the stomach.

Dr. Wolff employs an electrode constituted of a small stomach-tube with two fenestra; through the tube passes a small insulated copper wire, which projects from one of the fenestra; this extremity is denuded of its insulation for about two or three inches, and is twisted into a small spiral, which is slipped through the fenestrum back into the tube so that it cannot come in contact with the stomach.

DR. HORATIO R. BIGELOW, of Philadelphia, read a paper on "Alternative Currents," which he stated was a review of two ingenious and scholarly papers by Mons. D'Arsonval.

DR. J. H. KELLOGG, of Battle Creek, Mich., presented two new electrodes, one of which is flexible, slightly adhesive, and to be used dry. It is made by dissolving twenty ounces of the best gelatin in ten ounces of boiling water and adding ten ounces of glycerin and two drams of sodium chloride. The liquid is heated and

ten ounces of finely pulverized gas-carbon (graphite) added and thoroughly mixed.

To make an electrode a thin layer of the mixture is poured into a shallow tin pan of the size desired for the electrode, the inner surface of which is besmeared with vaselin. Upon this layer is placed a piece of sheet lint of sufficient size to allow the edges to be turned up about one-half inch around the sides of the pan. Upon this is poured more of the mixture, sufficient to saturate and cover the lint; another piece of lint is applied, and the process is repeated until a suitable electrode is cast. Two layers are usually sufficient. A piece of brass-wire cloth, to one corner of which a binding-post has been attached, is next applied, and over this more of the mixture, and then another piece of lint. The wire cloth and the last layer of lint may be a trifle smaller than the electrode is desired to be. Lastly, the upturned edges of the first layer of lint are folded over the back of the electrode, and a sufficient quantity of the mixture applied to hold them in place. When the electrode is cold and sufficiently hardened it is carefully removed from the mould. If the surface of the electrode is not perfectly smooth, or becomes roughened by use, it may be polished with a hot spatula; if the electrode becomes cracked, or its surface very irregular, it may easily be repaired by applying a little of the hot gelatin-mixture and smoothing with a spatula. This electrode is light, clean, adhesive, a good conductor of electricity, and durable.

The second electrode consists of a metallic vacuum-cup, to which a binding-post is attached, a moist sponge being placed in the cup. In practice the air is exhausted from the cup, causing it to adhere firmly in position, at the same time bringing the tissues in close contact with the sponge.

DR. THOMAS W. POOLE read a paper entitled "Some Suggestions as to the Mode of Action of the Galvanic Current in Gynecological Practice," in which he ascribed to electricity, in gynecological practice, a paralyzant action upon the motor nerves of involuntary muscles, as a result of which contraction of the arteries takes place. A moderate effect, quickening the blood-stream, accounts for the beneficial effects occasioned, while an excessive outflow of blood into the veins causes increased pain, tumefaction, and an aggravation of all the symptoms.

He held that the effects produced by the electric current upon protoplasm, upon the blood-corpuscles, upon the heart of frogs in arresting its pulsations, upon the muscles in inducing the earlier onset of rigor mortis, are all what might be expected from an agent inimical to nervous activity.

DR. HENRY MCCLURE, of Norfolk, England, presented a paper entitled "Electrical Contact-force," in which he considered the changes taking place and the forces generated at the junction of dissimilar metals or other substances.

He also elaborated Rust's theory of thermo-electricity, which holds that the electro-motive force is proportional to the rate of speed at which heat passes the two *junctions*.

Dr. McClure considers true contact-force at the junction of two dissimilar metals or substances to be of the nature of a static strain, heat in the thermo-couple being the means of breaking down such a strain and converting static into kinetic electricity. Whenever a static strain is broken down a current is produced. True contact-force may be seen in insulators as well as in conductors. The striking effects of frictional electricity are due to the same cause—contact of dissimilar substances—and by their contact electricity becomes transferred from one to the other, the violence of friction being mostly necessary to aid the transfer, so that one becomes positive and the other negative. When such a strain is broken down, as in disruptive discharge, a current is produced having electrolytic effects. In good conductors such contact-forces are feeble; electricity seems to slip through the fingers of a metal, as it were, and the driving force that it can exert is weak, while an insulator gets a good grip and thrusts it along with violence. The metals do not all grip electricity alike. Iron is a metal the atoms of which grip positive electricity better than negative electricity; a positive current gets propelled in iron from hot to cold; copper, on the other hand, acts similarly on negative electricity.

DR. FOVEAU DE COURMELLES, of Paris, presented a memorial upon "Medicamental Electrolysis," in which he described the method and the conditions in which he made electrical applications by means of decomposable medicaments. For tumors, synovial cysts, glands, wens, stone, in fact in all abnormal conditions of local hypertrophy, the continuous current was employed in conjunction with medicinal agents, such as the iodides, the salts of lithium, the bicarbonate of sodium. The action is facilitated by the application to the skin of a kind of cupping-glass.

The pain of neuralgia, rheumatism, hepatic and renal colic, can be made to disappear by the employment of the continuous descending current in conjunction with such medicaments as opium, aconitine, and quinine.

Anesthesia and muscular atrophy may be improved by continuous ascending currents with such adjuvants as strychnine and phosphate of lime.

Paralysis, disorders of the nervous system, abnormal functions of various kinds are remedied by interrupted currents, with the introduction into the organism of tonics or excitants, according to the necessities of the case. Baths of static electricity, with medicamental absorption, and descending electrical shower-baths are useful adjuvants. Good may be expected to follow the application of the same principle in the treatment of vesical calculus.

Dr. de Courmelles reported a case of articular rheumatism, one of fibroma of the uterus, one of enlarged prostate, two of gonorrhea, and one of hemiplegia in which satisfactory results were obtained by the employment of the method indicated.

DR. EPHRAIM CUTTER, of New York, presented a communication on "The Galvano-cautery: Its Use in Removal of Piles and Growths," in which he insisted upon the employment of a good battery, which, if a storage-battery, should be well tested as to its connections.

He recommended heavy conductors of pure silver as less bulky and more flexible than copper; carbon and zinc plates, variously connected, so as to be portable, and not break; and broad connections, with as few breaks as possible.

The best battery-fluid is constituted of one ounce of sulphuric acid and eleven ounces of a saturated solution of sodium bichromate, which should be cold.

Dr. Cutter reported seven cases of various new formations in which employment of the method indicated yielded satisfactory results.

DR. A. H. BUCKMASTER, of Brooklyn, presented a report of "A Case of Retroflexion and Cystic Degeneration of the Ovaries Treated by Hysterorrhaphy Unsuccessfully and Cured by Electricity," occurring in a young, unmarried woman, in which three applications a week were made, with the clay electrode on the abdomen and a platinum tip covered with a large mass of moistened cotton in the vagina.

DR. G. H. WHITCOMB, of Greenwich, N. Y., presented a report of "A Rare Case of Twin Intra-uterine and Extra-uterine Pregnancy Treated by Electricity," occurring in a large, robust woman, thirty-six years old, who in the twelfth week of her second pregnancy, complained of sudden severe pain in the region of the left cornu of the uterus, with evidences of local peritonitis.

Under appropriate treatment the acute manifestations subsided. The uterus was anteverted and prolapsed, the cervix resting upon the perineum just above the sphincter ani and the fundus lying forward against the bladder, causing vesical tenesmus. The organ was unusually large for the corresponding period of gestation, owing to the previous hyperplasia and to the encroachment of a large mass on the left, which seemed to be continuous with, and a part of, the uterus. This body was as large as an orange and supplied with numerous pulsating vessels; not clear in outline, but firm and elastic in consistency. The uterus, from its size, shape, and consistency, unquestionably contained a fetus. The history, together with the conditions found, indicated as clearly as possible that there was also either a tubo-uterine or an interstitial pregnancy, or one in a rudimentary cornu.

With a ball electrode in the vagina below the mass, and a small flat electrode upon the abdomen directly over the mass, a mild and increasing faradic current was passed for fifteen minutes daily during two weeks. The symptoms improved continuously in all respects, though some pain persisted. The enlargement diminished noticeably. The impression gained by constant watching was that it had gradually receded into the uterus. At the end of several days a slight, dark-brown discharge, lasting for an hour, occurred, which returned on the following day, when it was attended by a periodical pain. Abortion promptly following, the patient expelled the fruits of a twin-conception. The cord of the fetus first delivered was broken; that of the second was attached to a placenta on the right side of the anterior wall of the uterus near the fundus.

In little more than a year the woman gave birth to a healthy child at term; and, so far as known, after an uneventful gestation and labor.

DR. A. G. HENRY presented "A Report of Three Cases of Uterine Tumors Treated with Galvanism," in which a thirty-two cell battery was used. As in neither of the cases a sound could be introduced into the uterus more than one and a half inches, a small olive-shaped tip for the intra-uterine electrode was employed.

In each case negative cauterizations were invariably made. The strength of the current ranged from twenty to seventy-five milliampères—usually after the first few applications from thirty-five to fifty-five. The duration of the sittings was from five to ten minutes. In all three cases the treatment was successful.

NEW YORK STATE MEDICAL ASSOCIATION.

Eighth Annual Meeting, held in New York City, October 28, 29, and 30, 1891.

FIRST DAY—OCTOBER 28TH.

THE President, DR. STEPHEN SMITH, of New York County, delivered an address on "The Art of Teaching Medicine," in the course of which he said that every teacher should bear in mind Bacon's quaint saying: "He that questioneth much, shall learn much," and should not allow the student to be simply receptive. It would hardly be necessary to enunciate such well-known principles, but that the current methods of teaching medicine are unique. The medical student *reads* medicine; his individuality is lost in the class. The whole policy of most medical schools seems to be to make the professors and not the students the prominent feature.

The ideal method of teaching medicine would divide the classes into small sections, grading the students according to their individual capacity and proficiency. Recitations would be held at proper intervals, and practical demonstrations given whenever practicable. The knowledge of each student would be tested by examinations, before he would be permitted to pass to the next grade. That the ancient art of teaching medicine can be revived has already been practically demonstrated with gratifying success by one of the large metropolitan schools of medicine.

DR. ELBERT T. RULISON, of Montgomery County, read a paper on "The Use of Chloroform in Labor," in which he urged the more general employment of chloroform during labor, cautiously administered, avoiding complete anesthesia, in order to relieve pain, diminish shock, and avoid frequent ruptures of the perineum.

DR. OGDEN C. LUDLOW, of New York County, heartily indorsed the employment of chloroform in labor, which he preferred to ether in all cases except in those requiring severe and protracted operation, as he considered the greater control over delivery given by chloroform to more than counterbalance any dangers inherent in the anesthetic itself. The best inhaler, which is always accessible, is a tumbler, into which is pressed a handkerchief, or some absorbent cotton.

DR. M. W. TOWNSEND, of Genesee County, considered the routine use of any anesthetic during labor to be meddlesome midwifery. He deprecated the too common practice of administering anesthetics rapidly and in such a way as to produce partial asphyxia. In cases of labor in which he deems it necessary to employ chloroform, he has the patient to count aloud slowly, and when she ceases counting, the anesthetic is immediately withdrawn.

DR. GEORGE E. FELL, of Erie County, read a paper, entitled "Forced Respiration—Continued Observations," in which, in addition to the saving of five lives by himself and of one by a foreign physician, by means of this method of forced respiration, already reported, he stated that he had saved three more, and a number of other physicians had met with like success. While the method had chiefly been used in cases of

opium-poisoning, it would probably prove equally useful in cases of drowning and of traumatic shock.

Dr. Fell insisted upon his claims to priority, and exhibited the apparatus employed to carry out the procedure. He stated that forced respiration had been employed for many hours at a time without damage to the patient's lungs, and that on various occasions, when Sylvester's method of artificial respiration had proved utterly futile, this method had brought prompt relief, and in many instances, a cure.

Dr. Henry C. Van Zandt, of Schenectady County, read a paper on "Preventive Medicine," in which he deprecated the traditional reluctance of physicians to educate the masses on medical subjects, thus actually favoring the development of quackery. The advanced state of sanitary science among the Jews up to the time of their scattering abroad among other nations probably had much to do with their longevity. Modern sanitary science is responsible for a remarkable lowering of the death-rate in many of the principal cities, and an increase in the average duration of human life.

Dr. John Shrady, of New York County, read a paper on "The Theories of Rheumatism," in which he admitted that a study of the much-vexed question of diet in its relations to rheumatism does not yet admit of definite conclusions; in this connection, however, the observations of Dr. Alexander Hadden on animals are interesting. He maintains that graminivorous animals are most commonly affected by rheumatism, and points to the frequency with which calcareous deposits take place in birds. Dr. Shrady was not willing to admit the truth of the microbic theory of rheumatism; he thought that the drift of modern opinion concerning the etiology of rheumatism was in the direction of an irritant seeking the most convenient way of escape from uncongenial surroundings.

Dr. Alfred L. Carroll, of New York County, opened the discussion on "Acute Diffuse Peritonitis." He considered the histology of the peritoneum, a large part of which is devoted to suspensory purposes, or forms extravagant pouches, which give an enormous extent of endothelium, the stomata of which are connected with an elaborate system of lymphatics. In short, its function of lubrication is subordinate to that of absorption.

When exudation into the peritoneum takes place, it depends chiefly upon the etiology of the condition. The exudation is commonly plastic when the peritonitis arises by extension from adjacent inflammation, or as a result of contusion and manipulation. Dr. Carroll did not think it proper to ascribe the origin of the pus, and other cell-elements in peritoneal exudates, exclusively to the migration of leucocytes.

The part played by microörganisms, or by the products of fermentation caused by them, has not yet been determined; that is a problem for future bio-chemistry to solve.

The differential diagnosis is not infrequently a matter of some difficulty, because some cases pursue an afebrile course, or are even accompanied by a subnormal temperature, and because even the classical symptom, pain, may be absent. At first there are often only the physiognomy and the decubitus to guide the diagnostician. The diagnosis is still more difficult when diffuse peritonitis supervenes upon preëxisting maladies, or upon traumatism.

Dr. Carroll emphasized the general proposition that the therapeutic indications are not only modified by, but are altogether dependent upon the causative factors. When intense pain menaces the heart, morphine is temporarily useful, but when surgical methods are as imperatively demanded as they are in cases in which the inflammation is caused by penetrating or strangulating lesions, no further reliance should be placed on this drug. In other than surgical cases peristalsis is a "bugbear," and is inconsistently dreaded, for, when tympanites occurs, peristalsis ceases. Small "persuasive" doses of calomel given at an early stage will often happily prepare the way for slowly administered enemata. Belladonna deserves more attention than it has hitherto received, as it deadens the sensibility of the nerve-centers and allays pain; it diminishes reflex irritability and tends to relieve constipation and to support the heart embarrassed by pulmonary compression as well as by its own enfeeblement. Some of the cases in which Mr. Tait achieved success by the early administration of Seidlitz powders may really have been instances, not of peritonitis, but of the "fever of non-elimination." When a purulent exudation is present, or is likely to occur, quinine, which retards the migration of leucocytes, is indicated. Stupes and light warm fomentations are more philosophical than the depressing refrigeration of ice-coils. In severe cases a tendency to a lowering of the temperature is often of evil omen, and when this exists it should exclude the use of all depressants.

Dr. Heneage Gibbes, of Ann Arbor, presented a communication, in which he discussed the comparative anatomy of the peritoneum and the relations that the bloodvessels and lymphatics bear to this important membrane. He detailed experiments that he had made on animals: Fluids containing pure cultures of various microörganisms were injected into the peritoneal cavity, with negative results; but when such injections were made into the systemic circulation, plugging up of the vessels and other marked effects were observed. The lymph that exudes into the peritoneal cavity is apparently capable of rendering a certain quantity of noxious material innocuous. Tuberculous material had even been injected into the peritoneal cavity without the development of the slightest tuberculous inflammation of the peritoneum.

Dr. Victor C. Vaughan, of Ann Arbor, in a communication, particularly considered the relation of microorganisms to peritonitis. No one species of organisms has been found to be invariably present. If the peritoneum be entirely free from irritation, the injection of germs suspended in distilled water has no effect, but if the suspension contain, for instance, bits of agar-agar, peritonitis follows the injections. Peritonitis can be induced by the injection of sterilized emulsions containing one drop of croton oil, the absence of microörganisms being proved by culture-experiments. Sterilized preparations of trypsin, injected into the peritoneal cavity, produce peritonitis; so that, aside from contained germs, the contents of the intestines introduced into the peritoneal cavity are sufficient to cause peritonitis.

Dr. E. D. Ferguson, of Rensselaer County, said that clinically there are cases that do not correspond with

the usual ideas of infective peritonitis—for example, cases with clear effusion, which recover completely, with or without paracentesis. Cases of toxemia sometimes closely simulate diffuse peritonitis. The object of treatment should be "to remove irritation;" but, of course, it is often difficult to determine the cause of irritation. Saline laxatives are often useful, when such remedies are not absolutely contra-indicated, and at the head of the list is to be placed magnesium sulphate.

DR. HAROLD C. ERNST, of Boston, accepted it as proved that most acute inflammatory and suppurative processes in the human body depend upon the activity of one or more forms of bacteria. As a result of some experiments that he had made, he concluded that acute peritonitis could not be produced in the lower animals except by the action of bacteria or their products.

DR. JOHN CRONYN, of Erie County, cited a case in which the diagnosis of metastatic tuberculous peritonitis in a patient having pulmonary tuberculosis had been fully confirmed by the post-mortem examination. A point of practical importance in the treatment of peritonitis is the administration of a combination of opium with quinine. By associating these drugs larger doses can be given without producing either narcotism or cinchonism.

DR. GEORGE T. HARRISON, of New York County, considered the subject from a gynecological standpoint. When peritonitis is well established, purgatives can only be harmful. He had never seen the symptoms ameliorated by warm applications, while the employment of ice-bags or coils moderates pain and peristalsis, often localizes the inflammation, and makes the patient comfortable without resort to large doses of opiates.

DR. WILLIAM MCCOLLOM, of Kings County, made a strong plea for the recognition of an idiopathic form of peritonitis, basing his position on the known liability of certain individuals to disease of the serous membranes, as well as upon his personal experience. At one time, while practising medicine in Vermont, where the winters are severe and the temperature very variable, he frequently treated cases of peritonitis occurring almost exclusively in males whose occupations exposed them to the inclemency of the weather. At the time referred to, Dr. Alonzo Clark was urging the adoption of the "opium treatment." Dr. McCollom had ever since employed this plan of treatment; he was loath to relinquish a method that had stood the test of about forty years of practice to take up the use of laxatives, a method of treatment that had proved most unsatisfactory.

DR. NICHOLAS SENN, of Chicago, considered the different varieties of peritonitis. He described the plastic form as a process that remains circumscribed, in this respect being widely different from septic peritonitis, in which the primary cause continues to multiply. Owing to the absence of pain and fever, and frequently to the existence of even a general feeling of well-being, many cases of virulent puerperal peritonitis are often not recognized during life. The pulse that rapidly rises to 150 or 200 per minute is, however, significant. Dr. Senn related the history of a case that he had recently seen, in which the diagnosis seemed to lie between ascites and a large ovarian cyst. He had himself looked upon the case as one of tuberculous peritonitis, with localized ascites. On performing laparotomy, nothing but a true ascites could be found, and recovery followed the employment of drainage for several weeks. In fact, the case was one of hydrocele on a large scale—a passive form of peritoneal inflammation not due to infection from without, but to a loss of equilibrium between secretion and absorption. Dr. Senn expressed the belief that these cases are more common than is usually supposed. Reasoning from what is known of idiopathic inflammations of the meninges and pleura, he most emphatically expressed his belief in the existence of an idiopathic form of peritonitis.

DR. MARCY, of Boston, expressed the opinion that in cases of tuberculous peritonitis laparotomy often results in great benefit to the patients, although the reason for this may not yet be well understood. He cited an interesting case in which frequent and large tappings of the abdomen failed to prevent rapid reaccumulation, but in which a cure was promptly effected by establishing permanent drainage. The explanation is probably to be found in the consequent relief of the mesentery from undue pressure. Dr. Marcy cited statistics showing the safety of exploratory laparotomy, and advised a more frequent resort to this valuable measure.

DR. T. D. STRONG, of Chautauqua County, reviewed the "Opium Treatment." The degree of tolerance to opium is to a certain extent a measure of the severity of the attack. In a very desperate case, in a boy ten years old, eighteen grains of morphine were administered in thirty-six hours, and the lad appeared in no way drowsy, but constantly complained of pain. When this point was reached, a change for the better appeared, and the boy made a slow but complete recovery.

DR. J. LEWIS SMITH, of New York, considered the subject of "Peritonitis in Early Life." No age, he stated, is exempt from peritonitis. It has long since been shown that the fetus sometimes becomes nonviable and perishes in consequence of peritonitis, and that the most common cause of this is inherited syphilis. Peritonitis may prove fatal before birth, or, if the child is born alive, death usually soon results. Peritonitis of the newly born is by no means uncommon: the inflammation is commonly caused by the entrance of septic matter into the system at the umbilicus, from foul umbilical dressings or from foul water employed in washing. The pathogenic factor resides in microbes.

Primary or idiopathic peritonitis is that form that occurs when there has been no antecedent disease that might give rise to it. Its occurrence is denied by some writers, but that it does occur, and not infrequently, is proved by a large number of cases reported by different observers.

During infancy and childhood peritonitis may occur from a considerable number of causes, as from septic infection or blood-poisoning; in connection with erysipelas; from disease of the abdominal viscera—more frequently of the hollow organs than of the solid viscera; as a result of appendicitis or typhlitis. Children less frequently than adults have ulceration of Peyer's patches in typhoid fever, but it sometimes does occur, with subsequent perforation and fatal peritonitis. Another cause of peritonitis is traumatism. A case of fatal peritonitis is on record following tapping for a congenital hydrocele. In females, peritonitis may result from gonorrhea, the inflammation passing from the

vagina to the uterus, and thence through the Fallopian tubes to the peritoneum. Tuberculous peritonitis occurs much more frequently in infancy and childhood than in adult life.

The symptoms of peritonitis in children are usually quite distinct, although in some cases they are so obscure that it is very difficult to make a diagnosis. The treatment must be instituted early and must be judicious. The indication is to subdue the inflammation as soon as possible and at the same time to employ such dietetic and medicinal remedies as will sustain the strength and prevent heart-failure, which is the ordinary cause of death. It is important that the patient should remain quietly in bed, with the least possible movement of the body and lower extremities. In the ordinary forms of peritonitis, purgatives act injuriously in children, as in adults. During the active period of the disease it is better not to employ any treatment whatsoever for the purpose of opening the bowels, even if one or two weeks elapse without a stool. As for drugs, opiates are the chief reliance. They relieve not only the tenderness and pain, but also the vomiting, and produce a quiet state of the intestines. The remedy should be given in doses sufficiently large to produce this effect. A child of twelve years can take half a grain of opium every two or three hours, or sufficient to secure sleep. The removal of the cause of the disease, if it can be effected by means of a surgical operation, should be carefully considered.

DR. E. G. JANEWAY, of New York, stated that the diagnosis of acute peritonitis is at times extremely difficult. Tympanitic distention of the bowels may be present, as well as pain and fever, without any peritonitis; it is only by closely watching such cases that a correct conclusion can be arrived at. Dr. Janeway reported the case of a boy, four years old, who presented high fever, constipation, and pain in the right iliac fossa, with tenderness so considerable that he had to be examined under chloroform. This condition continued for four days, all of the symptoms indicating peritonitis. On the fourth night the boy slept well, on the following morning his temperature was 99°, and two days afterward he was well enough to go out. A pneumonia or a pleurisy may cause reflex pains in the abdomen, with marked distention. The symptoms of peritonitis may also be simulated by hepatic colic—more rarely by renal colic; in either condition there may be fever, distention of the abdominal walls, and pain. Then again, there may be cases of peritonitis accompanied by diarrhea, without fever and with very slight pain.

DR. NICHOLAS SENN, of Chicago, delivered the Address in Surgery, taking for his subject "The Surgical Treatment of Pyloric Stenosis." He divided the subject into, first, the operative treatment of cicatricial stenosis of the pyloris; second, the operative treatment of carcinoma of the pylorus. He stated that cicatricial stenosis of the pylorus frequently follows adjacent ulceration or traumatism. At first the symptoms are those of obstruction to the passage of the food, to which subsequently those of compensatory hypertrophy and dilatation of the walls of the stomach are superadded. The operative treatment of a cicatricial stricture at the pyloric extremity of the stomach consists in performing pylorectomy; in digital divulsion of the stricture through the wound in the stomach; and in the formation of a new pylorus by the pyloro-plastic operation of Heineke-Mikulicz; or, in establishing a new outlet from the stomach into the small intestine by performing a gastro-enterostomy.

Dr. Senn reported fifteen cases in which he had operated for the relief of pyloric stenosis, and presented the following propositions:

1. Pyloroplasty, as devised by Heineke-Mikulicz, is the safest and most efficient operation for cicatricial stenosis of the pylorus.

2. Pylorectomy is a justifiable procedure in the treatment of carcinoma of the pylorus when the disease is limited to the organ primarily affected, and when the patient's general health furnishes no contra-indication.

3. In the treatment of malignant stenosis of the pylorus, gastro-enterostomy, with the aid of large, moist, perforated plates of decalcified bone, should be resorted to as soon as a positive diagnosis can be made and a radical operation is contra-indicated.

CORRESPONDENCE.

THE TRANSMISSION FROM ONE PERSON TO ANOTHER OF THE POISON OF RHUS TOXICODENDRON.

To the Editor of THE MEDICAL NEWS,

SIR: In a contribution to THE MEDICAL NEWS (Oct. 24, 1891, p. 484), entitled "Unusual Mode of Transmission in a Case of Dermatitis Venenata," Dr. Cantrell states that he had found "but one parallel case" to the one therein reported, "wherein the disease was contracted by the mere handling of a person affected."

In 1873 (*Amer. Journ. Med. Sci.*, vol. lxvii, p. 436) I reported the following cases:

"In June, 1871, Mrs. V. suffered very severely from a burning and itching eruption covering her entire face, neck, both mammæ, external genitals, extending along the inner surface of both thighs, both hands, wrists, and portions of her abdomen. Her husband, at the same time, suffered with a similar eruption, though not so severe, on both hands, and an infant had it very slightly about the mouth and chin. A week previous to the appearance of the eruption, the husband and wife had passed an afternoon at a picnic, and he had fastened his horse to a bush covered with a vine, the character of which he had not observed. The wife did not approach the plant, and the child had been left at home."

In the commentary following the report of these and other cases, I called attention to the readiness with which the poison "can be conveyed to other parts of the body by the contact of the part which may have received the poison from the plant, and from one individual to another, even though the first may not at all, or only very slightly, suffer from its poisonous action." This conclusion was reached after an extensive, and, as I supposed, an exhaustive examination of the literature of the subject. As it is admitted that the poison may be conveyed by the hands to other parts of the body, it would seem clearly admissible that one person should transmit it to another, by actual contact, even though the first might not be susceptible to the poison.

In conclusion I recall attention to the fact, cited in the article previously referred to, that Dr. Canfield,[1] of Monterey, Cal., as early as 1859, reported the successful treatment of the disease with the local application of the balsam-like juice of the Grindelia robusta.

SAMUEL C. BUSEY.

WASHINGTON, D. C., October 27, 1891.

POISONING BY IVY AT SECOND HAND.

To the Editor of THE MEDICAL NEWS,

SIR: The case of Dr. Cantrell, reported in THE MEDICAL NEWS of October 24th, reminds me of a similar instance. Miss E. W. spent the night with her sister, Mrs. C., whose husband was obliged to be absent on business. Mr. C. had been poisoned about the head and neck with ivy a few days before leaving home. The pillow-case on which he slept was not changed, and his sister-in-law, using it, became poisoned about the face and neck in consequence thereof, no other opportunity for contracting the disease existing.

While on the subject, I would like to call attention to a plan of treatment that I have found most successful. As everyone of experience knows, the success with the ordinary remedies employed varies greatly, relief sometimes being prompt and at others most tardy. The fluid extract of Virginia snakeroot (serpentaria) is undoubtedly a specific. Applied to the irritated parts in full strength, "sopped" on, repeating the application from every two to four hours early in the attack before an eczema is engendered, it will promptly arrest the disease and act as an antidote. I have used lead-water and laudanum, solution of carbolic acid, lime-water applications, sodium solutions, grindelia robusta, and most other so-called remedies, but with none was I sure of a satisfactory result. With the serpentaria the result is certain as well as speedy. I need scarcely add that the suggestion is not original with me. Yours very truly,

J. B. WALKER.

1617 GREEN ST., PHILA., October 26, 1891.

SUPERNUMERARY FINGERS AND TOES.

To the Editor of THE MEDICAL NEWS,

SIR: In THE MEDICAL NEWS for April 13, 1889, I reported the case of a colored child that had a supernumerary digit attached by a thin pedicle to the outer side of each hand. The extra fingers were removed.

Another case was that of a white adult who had six well-developed toes on each foot, and had also, at birth, six fingers on each hand, as in the first case reported. The extra members were removed in infancy.

Since making the above report, I have observed a number of cases of supernumerary toes and fingers. Mr. N., a white man, has two children, one having six well-developed fingers on each hand and six well-developed toes on each foot; the other child having six well-developed fingers on his left hand and six well-developed toes on his left foot.

A colored woman had six children (by about as many men), each child having six fingers on each hand and six toes on each foot. The extra members, none of which were thoroughly formed, were all removed in infancy. In none of the foregoing cases were the anomalies inherited or transmitted.

Again, a colored man has been the father of seven children (six of whom had the same mother), five of whom were born with a supernumerary finger attached by a pedicle to the outside of each hand, and an extra toe attached in the same way to each foot. One child had six fingers on each hand, the feet being normal. The hands and feet of the other child were normal. All the extra fingers and toes were almost thoroughly developed, having bones, joints, and nails. The extra members were all removed without trouble. In this instance the anomaly existed in children, father, and paternal grandfather—a somewhat interesting and remarkable fact. I have made no special effort to collect these cases, they having been incidentally met with.

Very respectfully,

W. F. DREWRY, M.D.

CENTRAL LUNATIC ASYLUM, PETERSBURG, VA.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM OCTOBER 27 TO NOVEMBER 2, 1891.

BALL, ROBERT R., *First Lieutenant and Assistant Surgeon.*—Granted leave of absence for one month, with permission to apply for an extension of one month.

MAUS, LOUIS M., *Captain and Assistant Surgeon.*—Is relieved from duty at Whipple Barracks, Arizona Territory, and ordered to Fort Apache, Arizona Territory, for duty.

RICHARD, CHARLES, *Captain and Assistant Surgeon*—Is relieved from duty at Fort Logan, Colorado, and will report in person to the commandant of the Military Prison, Fort Leavenworth, Kansas, for duty.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING OCTOBER 31, 1891.

HARVEY, HENRY P., *Surgeon.*—Ordered to Receiving-ship "St. Louis."

FLINT, JAMES M., *Surgeon* —Detached from the Smithsonian Institute, and ordered to the U. S. S. "Miantonomoh."

HEYL, T. C., *Surgeon.*—Detached from Receiving-ship "St. Louis," and wait orders.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U. S. MARINE-HOSPITAL SERVICE, FOR THE TWO WEEKS ENDING OCTOBER 24, 1891.

PURVIANCE, GEORGE, *Surgeon.*—Upon completion of duties as Chairman of Examining Board to Inspect Marine Hospitals at St. Louis, Mo.; Cairo, Ill.; and Cincinnati, Ohio, October 16, 1891.

GODFREY, JOHN, *Surgeon.*—To represent the Service at the meeting of the American Public Health Association, October 14, 1891. To inspect Marine Hospital at Louisville, Ky., October 14, 1891.

CARTER, H. R., *Passed Assistant Surgeon.*—Granted leave of absence for thirty days, October 17, 1891.

PETTUS, W. J., *Passed Assistant Surgeon.*—Orders to Norfolk, Va., revoked; to proceed to Cape Charles Quarantine for temporary duty, October 14, 1891.

KINYOUN, J. J., *Passed Assistant Surgeon.*—To represent the Service at the meeting of the American Public Health Association, October 17, 1891.

PERRY, T. B., *Passed Assistant Surgeon.*—To proceed to Norfolk, Va., for temporary duty, October 14, 1891.

GUITERAS, G. M., *Assistant Surgeon.*—To proceed to Gulf Quarantine for duty, October 20, 1891.

ROSENAU, M. J., *Assistant Surgeon.*—Granted leave of absence for thirty days, October 24, 1891.

ORIGINAL ARTICLES.

A STUDY OF ATROPHY.[1]

BY ROSWELL PARK, A.M., M.D.,
PROFESSOR OF SURGERY, MEDICAL DEPARTMENT UNIVERSITY OF BUFFALO; SURGEON TO THE BUFFALO GENERAL HOSPITAL.

I WISH to invite your attention to an historical review of certain characteristics presented by that diminution of volume or mass of an organ or part that is described in one word, *atrophy*, and perhaps less to its pathological than to its clinical side. Strictly speaking there is a great difference between arrest of growth and atrophy in the true pathological sense of the word, and yet, as surgeons see these cases, there is at times so little apparent difference between the respective results of the two processes that we make very little clinical distinction between them. At all events, without dealing just now with minute differences, let us see what of interest a discussion of coarser features may bring out. I wish here to acknowledge no small indebtedness in this connection to a work published in 1882 by Mondan, entitled *Recherches Expérimentales et Cliniques sur les Atrophies des Membres*, which emanated from the Lyons school, and which is based largely on observations made in the clinic of Ollier, than whom no more accurate observer of such matters is known. It is a brochure little known or read, at least in this country, but it will amply repay perusal.

In Petit's *Traité des Maladies des Os*, ii. 23, we find some interesting notions concerning muscular atrophy after fractures, expressed thus: "Atrophy or diminution is an accident which supervenes, not at the beginning, but later, by enfeeblement of nerves and arteries which continue to be compressed, either by exuberant callus or by too tight bandaging. These obstacles to free circulation may cause lack of nutrition or atrophy." In 1776 John Hunter put forth his theory, according to which sympathy figured largely in the process, and in which may be found the germ of the idea of atrophy by reflex action. In 1835 Nélaton insisted upon the importance of atrophy of the thigh among the signs of hip-joint disease. He stated that the arrest of development of osseous tissue was proportional to atrophy of soft parts, and that this was a rule to which there were very few exceptions. It is also observed, he stated, not only in spontaneous luxations, but in all those diseases that condemn a limb to prolonged rest. Thus he cited atrophy of the femur in the case of a necrosis of the pelvis. These ideas are elaborated in his great work (*Path. Chir.*, 1847, ii. 264).

In 1837 Curling published his "Remarks on Certain Forms of Atrophy of Bone" (*Med.-Chir. Trans.*, 1837, p. 336), in which he described a *concentric* and an *excentric* atrophy of bone. The former depends mainly on local causes, such as consecutive dislocations, caries, inflammations resulting from gunshot fractures, etc. He included here the bone in an amputation-stump, as well as the atrophy of ankylosed limbs. He speaks of *functional inertia*, and the influence of the central nervous system by which, in paralytics, healing of fractures is delayed. He shows how compression of the main artery supplying such organs as the liver, spleen, or kidneys, will lead to their diminution, and he considers at some length the atrophy of a bone-fragment broken from a main portion which contains the principal nutrient artery. The nutritive supply in such cases cannot be maintained, owing to the inextensibility of the Haversian canals; consequently the fragment slowly disappears. Under the head of excentric atrophy he deals mainly with osteo-malacia, which is a generalized process depending upon a constitutional condition.

Bonnet was alive to the importance of atrophic processes, and in his *Traité des Mal. des Articulations*, 1845, i. 217, he wrote: "Whatever the varieties which they present, according to anatomical conditions, chronic inflammations of the synovialis consecutive to mechanical injury engender always an atrophy, more or less marked, of the surrounding parts." In general this will be noted about the injured joint, but sometimes it extends further, and may affect an entire limb. But Bonnet was, perhaps, not the first, certainly not the only one of his day, to allude to atrophy as a significant accompaniment of chronic joint-disease. Malgaigne (*Anatomie Chirurgicale*, i. 166) directed attention to disappearance of the alveolar process when deprived of its teeth, to thinning of the cranial bones after trephining, and to atrophy of the ilium and femur after old and unreduced dislocations of the hip. Even for Malgaigne functional inactivity was the cause of diminished nutrition.

In 1845 Roux put forth certain noteworthy views (*Annales de la Chirurgie*, xv.), especially with refer-

[1] Read before the American Orthopedic Association, at Washington, D. C., September 23, 1891.

ence to atrophy of the deltoid in arthritis of the shoulder. For him the stretching of the muscle over a capsule distended with fluid was the sole and sufficient cause; an analogous condition occurring also at the knee.

Denonvilliers, in 1853, presented to the Société de Chirurgie, a boy of seventeen, whose right arm had been amputated ten years previously. At the time when he was exhibited there was a protruding necrotic stump, three centimeters in length. At the same meeting Guersant reported a similar case. He asked whether this was not due to a physiological elongation of the bone rather than to any fault in the operative technique. (*Bull. de la Soc. de la Chir.*, iii. 430.)

In 1858 took place another interesting discussion in the same society concerning the growth of amputation-stumps. (*Bull. de la Soc. de la Chir.*, ix. 450.)

Seeking a cause for this fact that in young subjects the bone frequently grows through the soft parts of the stump so as to perforate them, Marjolan attributed the longitudinal growth of the bone to "a certain degree of ostitis propagated from the upper epiphysis." This explanation, accepted by Broca, was denied by Chassaignac and Richet, who explained the relatively greater growth of the fibula in leg stumps to osteophytes developed at its extremity along with necrosis of the tibial end.

Humphry (*Treatise on the Skeleton*, p. 70) in 1858 called attention to the results of disease of bone. "If a limb be not used, the bones usually waste. . . . . These points are well illustrated by the conditions which the bones of stumps present when the limbs have long been amputated. In some the bones are cleared of their cancelli and reduced to a mere porous shell, the size remaining unaltered. In others they become much reduced in circumference, their walls retaining their proper density. In a third class the bones are small, and are also light and porous. In a case recorded by Larrey, of a man who died forty-one years after amputation of the arm near the shoulder, the scapula was as thin as paper, and the clavicle no thicker than that of an infant. I am *not aware* that a bone is *ever reduced* in length as a consequence of atrophy. If a part be disused by reason of paralysis or other cause, the bones may fail to attain their proper length; but, having attained it, I do not know that they ever lose it."

In 1859 Gosselin and Lejeune published important articles concerning muscular atrophy consequent upon fractures. They claimed that it always occurs in adults, the former reporting a case in which it existed ten years after the fracture. In children it is very much less common. Gosselin ascribed a more important part in producing atrophy under these circumstances to immobilization than to compression by bandage, and says: "the condition cannot be attributed to the surgical apparatus, but depends entirely on the primary affection." (*Gazette Hebdomadaire*, 1859, 130–64.

Coulon, in 1861 (*Traité des Fractures chez les Enfants*), speaking of fractures in children, says that perhaps "scrofula," that is "scrofula of bone," may, without producing caries, so weaken the osseous tissue by rarefaction as to predispose it to fracture. He says that he had never noticed muscular atrophy in children, perhaps because of the comparatively brief time in which their bones heal; but he fails to recognize that such periods of time are only relative. Referring to experiments made by Baizeau and Herpin concerning elongation of fractured bones, he says that he has not seen sufficient clinical proofs to permit him to acknowledge such a growth. The old subject once more came up before the Société de Chirurgie in 1884 (*Bull. et Mém.*, x. 521), when Kirmisson showed an amputation-stump in a lad of twenty, whose leg had been amputated when he was four years old. At the center of the stump was a bony projection, divided into two tuberosities by a transverse fissure. One of these belonged to the tibia, the other to the fibula, both having been fused together. Faraboeuf, while not rejecting Verneuil's views, suggested that such cases might be explained by a too rapid primary union with insufficient solidity of muscle and soft tissue, and that the condition might be prevented by causing the stump to heal by granulation. All agreed that in children amputation-flaps should be made exceptionally long.

To this peculiar atrophy affecting stumps Verneuil has given the name *physiological conicity*. He describes it (*Mémoires*, ii. 830) as occurring especially in arm and leg stumps; less often in thigh and forearm, because of lesser activity of the cartilages of the upper ends of the femur, radius, and ulna. He saw a large number of examples while distributing prosthetic apparatus at the Central Bureau of the Parisian Hospitals.

These statements of Verneuil's, if not founded upon the more elaborate explanations of Humphry, at all events corroborate them. It has been shown by Humphry (*Med.-Chir. Trans.*, xliv. 118) that the extension of the shaft takes place most quickly, and is most prolonged at the end where the bone can best bear the weakening consequent on the more rapid changes in the growing matrix; and that is usually the larger end. For instance, the lower end of the femur is larger, and is more favorably circumstanced for bearing weight and resisting muscular force than the upper end; and the ossifying processes are much more active, and are longer continued at the lower end than at the upper. In the

tibia the lower end is at a disadvantage in comparison with the upper, in consequence of its smaller size, the greater weight borne by it, and the violent shocks to which it is exposed from its closer proximity to the ground, and there is less growth here than at the upper end. In the upper limb the conditions are in many respects reversed, and growth is, consequently, more active at the upper part of the arm and at the lower part of the forearm.

Numerous other writers have alluded to the same condition. In one of Liston's cases the humerus projected in an extreme degree, and terminated in a hook-like process or exostosis. The latest contribution to the subject is by C. A. Powers (*Med. Record*, June 7, 1890, p. 641), who reports several instances.

But it is to the *Traité de la Régénération des Os* of Prof. Ollier that one turns with the greatest satisfaction for the experimental elucidation of this subject. Thus we find (i. 377) a long chapter upon the influence of irritation or of removal of various parts of bones upon their growth. After having established that the most common cause of hypertrophy of bones is irritation, he studies the causes of arrest of their development and their atrophy. Two factors come into play here: the destruction of tissue which may concern and favor their growth, and gradual failure in the evolution of such tissues. They necessitate a careful study of epiphysis, diaphysis, and conjugal cartilage, which Ollier has carefully carried out experimentally, and has shown that it is not by a precocious union of epiphyses to shaft that lesions of epiphyseal cartilage produce arrest of growth, but that the initial factor is arrest of proliferation of cartilage-cells. He has, furthermore, fully described the effect of fractures, of epiphyseal separations, of arthritis, and ankylosis in producing retractive tissue-changes. Mutilations of bone almost always produce arrest of development, which yet varies much according to whether the arthrodial or conjugal cartilages, the epiphysis, or the shaft have been most interfered with. Not only in the bone operated on do tissue changes occur. In the case of the forearm and the leg the parallel bone frequently undergoes alterations; sometimes this is in the direction of increase of thickness; that is, a compensatory hypertrophy, or, when one is pretty firmly fixed to the other, the more rapid growth of one forces it to assume a curve or some change of shape.

I have recently seen such alteration in the lower end of the fibula, apparently produced in the first place by a club-foot, upon the outer side of which the patient (a girl of sixteen) walked. Pressure upon the fibula being thereby removed and a certain tension produced by pull upon the external lateral ligament, while the whole weight was borne by the tibia, The result was that the lower three inches of the fibula assumed the exact shape of the arc of a circle of some ninety degrees.

So, for instance, after resection of the radius and ulna, the humerus, though not operated upon at all, ceases to grow with the same rapidity as does that of the opposite side; and, if the humerus alone has been attacked, the scapula on one side and the radius and ulna on the other are indirectly affected. These alterations are of a peculiar nature, and do not occur immediately; they take place by a gradual transition-state, during which they diminish in volume but increase in length. To this phenomenon, which he has most carefully studied, Ollier has given the distinctive name of *atrophic elongation*.

To the atrophic changes occurring in stumps, also, Ollier has paid great attention. But little has been said or written in this regard. Since the discussion in the Société de Chirurgie in 1858, alluded to, Humphry published two memoirs, and the more recent researches of Güterbock include nearly all the literature of the subject. Nearly everyone who has dealt with the subject has alluded to the atrophy which is most marked in connection with stumps that are nearly immobile; while the clinical fact was generally recognized, the interpretation remained for Ollier to enunciate. He lays great stress on the effect of *functional inertia*, and has sought to assign its correct position among factors. By observation and by experiment he came to the conclusion that function of a limb was a necessary stimulus to the growth of its skeleton. Suppression of this stimulus leads inevitably to atrophy of the part. This was but a systematic and comprehensive statement of generally-recognized facts.

In 1870 Boeckel published an interesting memoir concerning the effects of hip-joint disease in causing atrophy of the lower limb. He formulated these conclusions:

1. That arrest of growth is proportional to functional inactivity and atrophy of muscles.

2. That the bones are rarefied, and that active treatment, while shortening the course of the disease, acts also to lessen the extent of the atrophy.

3. That pelvic distortion (posture-deformities) tends to produce arrest of growth, exaggeration of the pressure transmitted through the femur, and atrophy of the muscles of the buttock.

4. That shortening affects the superior pelvic strait, but not enough to cause a serious obstacle to parturition (*Archives de Physiologie*, 1870–71, p. 435).

A thesis by Collette, in 1872 (*Thèse de Paris*, No. 182), marked an advance, since not only did he discuss the atrophy which accompanies certain forms of joint-disease, but he called attention to the increase of fatty tissue which often accompanies wasting of other soft parts. More than this, he

showed that curious atrophic freaks occur. Thus he cites a case of gonitis with wasting of both upper and lower limbs on that side, with great increase of fatty tissue, a notable enlargement of the breast, and a marked atrophy of the testicle on that side.

In quoting this case I am reminded of a case of my own, an amputation-stump in a young woman whose thigh I amputated seven years ago, when she was sixteen years old. The stump is now not conical, though it would be were it not that an overgrowth of adipose tissue makes it measure more in circumference than does the opposite thigh at the same height.

It was in 1873 that Reyher's careful study upon the influence of prolonged immobilization upon the joints appeared (*Deutsche Zeitschrift f. Chir.*, iii. 189). His microscopical studies of the various tissues implicated gave a peculiar value to his work. He never found any inflammatory phenomena, either hyperemia or tumefaction. Consequently, the atrophic changes of the adult or aged are merely a degeneration not caused by inflammation.

Sabourin, during the same year (*Thèse de Paris*, 1873), introduced a novel theory to account for the atrophies which accompany articular rheumatism, particularly those which one encounters about the shoulder in the deltoid, according to which it was due to irritation of the peri-articular fibrous tissue. To confirm this view, he pointed to the extreme soreness in muscular origins and insertions; in other words, to the extreme tenderness of masses of fibrous tissue in the neighborhood of any rheumatic lesion. Duchenne, in particular, has described an atrophic form of deltoid rheumatism, to which Sabourin quite eagerly applies his explanation.

It was not long before confirmations of Ollier's studies began to appear. Haab, in 1875, published a brochure, in which he corroborated Ollier's views concerning the normal growth of bone, and then he mentions pathological elongation after fractures, ostitis, and arthritis, and gives some of the cases reported by German surgeons. Assigning a secondary rôle to inertia and immobilization, he lays the principal blame upon the epiphyseal cartilage. For sympathetic elongation of the femur it is enough to have an irritation of the tibia sufficiently active and lasting. Failure of pressure upon the joint is a sufficient reason in his estimation, and he proposes to substitute the expression *elongation from lack of pressure*, for Ollier's term, atrophic elongation. Haab fails to apprehend how atrophy can produce elongation. He would account for many of these bone-changes by sympathy between femur and tibia, for instance, so that one is lengthened or shortened when the other is pathologically elongated, all of which, says Mondan, while criticising these expressions, is rather incomprehensible.

During the same year appeared the essay of Güterbock (*Arch. für klin. Chir.*, xvii. 584), in which he attributed the bone atrophy of an amputation-stump to an irritative action, the evidence of which he found in the occasional presence of osteophytes, and of other tissue alterations, such as the subperiosteal development of giant-cells, as described by Rusticzky. He considers these to be the results of functional inactivity in subjects of various ages and conditions. The experiments of Milne-Edwards, published fourteen years previously (*Annal. des Sciences Naturelles*, 1861), may have some bearing in this connection, as they appear to have in the thesis of Teissier (Paris, 1875). If we deprive animals (birds) of food containing calcareous elements, the volume of their bones diminishes, but their composition does not vary. At the end of three months the bones of such animals will weigh a third less than those of one normally nourished, but analysis would show no change.

Fifteen years ago Sir James Paget made these remarks in one of his published clinical lectures (*Lect. IV.* p. 208), speaking of wastings of limbs near affected joints: "This wasting occurs quickly in nearly all acute inflammations of joints; more slowly in the chronic inflammations. In the chronic it may be from disuse alone; in the acute it is not so, for it is much more rapid and extensive than in any cases of mere disuse. Compare, for instance, cases of fracture of the thigh with those of acute disease of the hip, and you will see how much greater is the wasting with acute disease than with disuse alone. Rapid wasting may be seen in the whole lower limb, especially in the thigh and the nates, in all acute hip-joint diseases; more slow wasting in the painless scrofulous diseases; less still in the chronic rheumatic. Wasting in the lower part of the anterior and lateral muscles of the thigh is quickly apparent in acute knee-joint disease; only less quickly in the chronic. . . . . It is, I repeat, not a mere wasting from disuse; it is far more rapid than that, more like what has been called acute atrophy of muscles, such as may often be seen in the swiftest cases of infantile paralysis. . . . . It seems dependent on disordered nervous influence, and often appears proportionate to the coincident pain, as if it were due to the disturbance of some nutritive nervous center, irritated by the painful state of sensitive nerve-fibers."

Two years later appeared Valtat's excellent thesis (*De l'Atrophie musculaire consécutive aux Maladies des Articulations*), which contained the following conclusions:

1. Most joint-diseases react energetically upon the nutrition of the muscular system.

2. Very early in such cases one sees a notable atrophy with paresis, more or less accentuated, of

certain muscles, particularly those pertaining to the affected joint.

3. This atrophy is not the result of functional inertia, or of inflammation of muscles, nerves, or cord; in all probability it is produced by the same mechanism as the other reflex phenomena.

4. It is a matter of no small importance; it increases usually *pari passu* with the joint-lesion, and remains, in the vast majority of cases, after this has recovered.

5. Its duration is commonly long, and is shows no tendency to spontaneous disappearance. Sometimes the muscles recover themselves by exercise, but by no means always.

6. They improve much more rapidly under the use of the continued current, or better still under the combined usage of both currents.

The clinical phases of the subject were excellently presented by Berguien (*Thèse de Paris*, in 1877) the same year. His was the first work in which the relations between the development of the bones along with their superimposed muscles were clinically discussed. Studying fifty-nine cases of hip-disease he demonstrated that there is always atrophy of the limb in these cases, and that it pertains to the bone as well as to the muscles, especially in very young patients; that the bone-atrophy is most marked about the joint where the effects of pressure would naturally be greatest, and that it is itself due to atrophy of bloodvessels; that deficiency of nutrition can be demonstrated by the thermometer; and that in those rare cases in which atrophy does not appear one may impute the fact to a coxalgia, coming on after the eighth year, when the subjects are very courageous and seek to keep the limb in active service.

In 1877 and 1878 Helferich published memoirs of considerable importance (*Archiv. d. Phys. und d. Anat.*, Mai, 1877, and *Deutsche Zeit. f. Chir.*, 1878, x. 324). He had demonstrated by numerous experiments, and as opposed to the views of Wolff, the exclusive rôle played by the conjugal or epiphyseal cartilages in longitudinal growth of long bones. This he did by excising them from growing young animals, and noting the failure to grow. In his second paper he studied the disordered relations that exist between necrosis and the coefficient of growth of various bones; he takes up the question of the frequency of inflammation in the different parts of the same bone, and after showing that it is in the vicinity of the cartilages that it occurs most commonly, he finds here the verification of his experimental work.

Passing by a number of brochures in which appeared nothing of great importance, De Clerville republished in 1880 (*Thèse de Paris*) a remarkable case of nearly total disappearance of the humerus, first broken at the age of eighteen, and twice after that. Only the superior and inferior epiphyses were left, and these were represented by small pieces. The patient died at the age of fifty-two, and the muscles of the arm presented a remarkable atrophy and fatty degeneration. Similar cases are of course reported in the work of Béranger-Feraud, but a case of this completeness or intensity is perhaps unique. It must be attributed largely to the influence of repeated irritations upon the vitality of the callus.

Lataste (*Thèse de Paris*, 1881) propounded in 1881 a novel explanation of the muscular atrophy following fractures. For him it depended not on immobilization, or compression, or lesion of nerve-fibers, but upon a certain degree of myositis, which was evidenced by local elevation of temperature.

In 1882 Segond (*Rev. de Chir.*, Août et Sept.) described a diminution in the caliber of the vessels in amputation-stumps or curtailed limbs. This is never consecutive to muscular atrophy, but sometimes precedes, sometimes accompanies it; and is, according to Segond, a very important contributing factor.

The causes, then, so far as generally ascribed, which lead to atrophy of parts, may be thus rehearsed:

a. Functional inertia.
b. Inequality or defect of nutritive supply.
c. Inflammation.
d. Something in the general condition.
e. Trophic-nerve disturbance.

These have been thus arranged by Mondan.

Within the present year Duplay and Cazin have published (*Archives Générales de Médecine*, Jan., 1891) the results of certain experimental researches into the nature and origin of muscular atrophies following diseases of joints, stating that of all the various theories advanced to explain atrophy of muscles following joint-lesions the "reflex" theory of Vulpian has found the most general acceptance, *i. e.*, changes originating in the irritated terminations of the articular filaments. This theory explains the rapidity of onset and the absence of the reaction of degeneration, either in the cord or in the large nerves. In their researches acute arthritis of the knee was produced by the injection of tincture of iodine or nitrate of silver, or by the actual cautery. In four or five days an appreciable diminution in size of muscles was invariably noticed; in eight or ten days they had become soft, and the atrophy steadily progressed until about the fifteenth day, when it either ceased or progressed much more slowly. The animals were killed at intervals up to the thirtieth day, when the various muscles of the healthy and affected limbs were carefully weighed. The loss of weight amounted in some cases to 50 per cent. Microscopic examination of the nerves of

these limbs shows that no lesion is usually present in the large trunks or in the motor filaments, but in articular nerves characteristic changes were constantly present. These changes are partly degenerative and partly inflammatory; they never show signs of spreading upward along the nerve-trunk, and no ascending lesion, such as has been described after amputations, could in any case be discovered, nor were there any alterations in the spinal cord, or nerve-roots, or ganglia.

The authors consequently deduce the following two conclusions: 1. That the muscular wasting following muscular lesions tells of a simple atrophy. 2. That this atrophy can be explained only by reflex action through the spinal cord, produced by the irritation of the terminal filaments of the articular nerve.

This appears to summarize fairly well the valuable literature of the century concerning an important topic. Such special attention as the writer had intended to devote to a further elucidation of Ollier's views on *atrophic elongation*, and a summary of his experimental work, will have to be postponed to another occasion, and made the topic for another communication.

EPILEPTIC INSANITY: ITS ETIOLOGY, COURSE, AND TREATMENT, BASED ON THE OBSERVATION OF ONE HUNDRED CASES.[1]

By EDWARD D. FISHER, M.D.,

ADJUNCT PROFESSOR OF MENTAL AND NERVOUS DISEASES, NEW YORK UNIVERSITY, MEDICAL DEPARTMENT; PROFESSOR OF MENTAL AND NERVOUS DISEASES, UNIVERSITY OF VERMONT.

In speaking of epileptic insanity, I would follow the definition of W. Bevan Lewis, given in his late work on *Mental Diseases*, viz.: "that form of mental derangement in the antecedent history, oncome, and further development of which we recognize an intimate connection with the epileptic neurosis." The distinction between epilepsy and epileptic insanity is often difficult, if not impossible, since, pathologically, we have the same ill-defined conditions present in each; and, as Lewis has well said, the question must often be asked in an asylum why such a patient is confined. Indeed, we find many in whom epileptic seizures occur only at rare intervals, and of whom the condition in the interparoxysmal state is apparently normal, but who during the paroxysms are maniacal, melancholic, and demented.

In our study of epileptic insanity we must proceed on the same lines as in that of the neurosis. We may, in fact, consider the insanity as a mental condition to which all epileptics are liable, and, while mental impairment is often not present in many cases during the intervals between the attacks, yet, from experience, I am inclined to think that it is more usually present than generally stated, because, while some examples of even great mental brilliancy may no doubt present themselves to the experience of all, the great majority show evidence of mental deterioration. The character becomes more or less brutal—even the face shows loss of the finer elements—and the emotional state, at least, becomes very unstable, making the individuals uncertain, impulsive, and usually suspicious. The most important element in epilepsy is the disturbance of the consciousness, especially when sudden in its onset. It stands out as the real diagnostic symptom of the disease. This indicates essentially an affection of the cortex of the brain, to which, if we are to discover its pathological basis, future study must be directed. The convulsions are of secondary importance, as they may be due to various irritative lesions of the brain, which may cause the same characteristics and distribution of the convulsions as occur in epilepsy, and yet have none, or few, of the peculiar mental disturbances seen in epileptic insanity. In fact, in cases of epilepsy of the so-called *petit mal* type, without convulsions, mental derangement is more common, and the prognosis is worse than in the *grand mal* type.

All forms of insanity have certain varieties of symptoms in common. In the first place, there is always a change in the personality; the relations of the individual or *ego* to the outer world are altered. There is always a concentration of the attention on the *ego*. We next observe some change in the feelings, thoughts, and actions, and usually first in reference to the feelings, which may be manifested by exaltation or depression; later, as a rule, in the thoughts, as represented by hallucinations, illusions, and delusions, these latter often arising in the attempt of the patient to explain to himself the reason of his changed emotions and altered relations to his surroundings. The last condition, as referred to the field of action or volition, is a natural outcome of the preceding, as thought cannot be known to exist without its expression in some act. The only other condition common, sooner or later, in insanity is dementia, which, when complete, represents a total abolition of the expression of the functions of the mind. In epileptic insanity we have all these functions more or less involved, and while each case differs from the others, yet in the aggregate certain well-defined characteristics stand prominently out. These may precede or follow the epileptic seizures, or even take their place, as in the *petit mal* form of epilepsy. In the study of this subject it is, therefore, necessary, in each case to get as full a description as possible of the premonitory

[1] Read before the N. Y. Co. Med. Soc., May 25, 1891.

symptoms preceding the paroxysm, of the paroxysm itself, and of the post-paroxysmal symptoms, as well as the condition between the seizures. As we shall see in our summary of the hundred cases that I have investigated for this paper, the premonitory symptoms may exist for a considerable time before the epileptic convulsion occurs, for hours, days, or weeks, and may assume the form of restlessness, illusion, delusion, or even sensory disturbance, so that one acquainted with the patient may be able to prognosticate an approaching seizure. The aura of epigastric discomfort is the most common, and the onset of the attack is usually very sudden, no warning, or one of but short duration, being the rule. On entering an epileptic ward it is not uncommon, if one patient has an attack, to see several instantly fall with the suddenness of an explosion.

In the study of my cases it has been very difficult to obtain any reliable previous history. A history of heredity—by which I mean either insanity or epilepsy in the parents or immediate family—was obtained in fifteen cases. Echeverhia places it at 28 per cent., while Reynolds puts it as high as from 31 to 53 per cent. Phthisis was present in the parents in seven cases. In the male cases, alcoholism—that is, excessive use of liquor—was given as the cause in nine cases; none in the females. Shock was noted in six cases among the females; insolation in three cases in the men; trauma in three cases in both the males and females. The history of epilepsy from childhood or infancy was given in twelve cases in the women, and nineteen in the men, with an indefinite account of a fall in some cases. Upon examining the cases with reference to the exciting causes of the seizures, in the sixty cases of women, the menstrual period in sixteen cases was either the only time of their attacks, during which they often were very frequent (in one case 100 attacks occurring in six hours), or they were increased at these times. A premonitory stage or pre-paroxysmal period was more frequent in the women, as shown by restlessness and irritability, existing often for days. A definite aura was rare: In the forty male cases its existence was only recorded in seven cases, and in three cases among the women. Those given were of the epigastric character, except in the case of one woman, who always complained of a sore throat, after which she became maniacally violent, requiring restraint. These figures are not perfectly accurate, but the dementia of many of the cases rendered it impossible to obtain more exact histories. It, however, approximates the general statements of the suddenness of the onset of the attacks in the epileptic insane. The character of the seizures is the same as in the neurosis, except that they are rarely unilateral. The mental condition following or preceding a seizure, and in the intermediate state, is what characterizes the disease. Masked epilepsy, or *epilepsie larvée*, in which mental derangement takes the place of the epileptic seizure, was not present in any of my cases, although attacks of *petit mal*, with excitement or depression, were not uncommon. The number of attacks varied from one to thirty a month, in the women seeming to be frequently increased at the menstrual period, and in most cases were both nocturnal and diurnal, rarely being limited to one or the other period. The attacks were usually both of the *petit mal* and *grand mal* type, the latter being only referred to in the number of attacks per month recorded. Mania or violence with assault, usually following the attacks, was present in fourteen cases of the women, and in twelve of the men; homicidal mania was recorded in nine cases of the women; melancholia, with suicidal attempts, was present in thirteen cases of women, while it was comparatively rare in men. Delusions of persecution were not uncommon, especially in the women; hallucinations were rare. Religious ideas of an emotional character were present in eleven male cases. What has been termed "religiosity" was very common among the women. Fully 50 per cent. were demented, and during the periods between the seizures many others on the slightest provocation showed great irritability. Perhaps no class of patients presents such sudden and violent outbursts as the epileptic insane, who, on coming out of a convulsion, often attack the nearest person; or after a mild seizure, perhaps under the influence of some delusion of persecution or fear, attempt to kill themselves or others. It is not unusual for them to associate the physician or nurse as the persecutor, or as one who has attempted to poison them, and they may under this delusion refuse all medicine or food. One marked symptom in most of these cases was the absolute unreliability of their statements; accusations of cruelty on the part of their attendants, and statements of being starved, are of frequent occurrence, often leading to investigation. In one case, a woman, after an attack, violently assaulted another equally irritable patient, and in the efforts to restrain her a bruising and discoloration of the arm was occasioned. She complained that she had been brutally treated and half-starved—an example of the untruthfulness of many of these patients. Fortunately, sufficient testimony was obtainable to disprove the first statement, and her generally well-nourished condition refuted the latter.

We have, as we see in the record of these cases, the physical and the psychical side, and it is the latter that principally interests us. The disease, then, represents a psychical entity, the chief characteristics of which are: (1) Irritability, as shown in excessive mental instability, often of a religious or erotic type;

(2) periodical attacks of mania or melancholia, with or without convulsions, accompanied by delusions of persecution, and a marked tendency to impulsive acts, rendering the patients dangerous to themselves and others; and (3) an early or late dementia.

The duration of the disease as revealed by these cases is interesting, as showing its chronic course, the longest being forty-four years, and the majority extending over from ten to twenty years. Most of them, also, had been epileptic for a number of years before their admission.

My paper was intended to be a clinical report of the cases that have come under my observation, and I shall not, therefore, go into the pathology. I would like, however, to refer to the investigations of Bevan Lewis in his late work, in which he claims to find degeneration, especially involving the small pyramidal layer of cells in the cortex of the brain, and consisting of fatty degeneration of the cell-nucleus with later changes, causing vacuolation. The cortex of the brain is certainly the seat of the pathological changes in epilepsy, and it is to it, as I have previously said, that we must direct our attention in our future studies.

Clouston states that epileptic insanity is not so common among women as in men, and does not respond so readily to treatment by the bromides. One feature—suicidal impulse—seems to have been quite frequent in my cases, and especially among the women. This is not common, according to Clouston and Cullerre, although both writers recount several cases. One peculiarity is the similarity, and even the exact reproduction of the same class of symptoms in each attack. In the case of the woman whose seizures always commenced with a complaint on her part of pain or soreness of the throat (which on examination revealed no local signs of disease), she soon after falls in a fit, and her first act on partially recovering consciousness is to attack the nurse. Of this she has afterward absolutely no knowledge. The attacks have always followed this course for the past three years. Automatic action is not rare, although only observed in one of the cases in which the patient after the attack always attempted to hide herself under the bed. In this case, associated with dementia, it was impossible to discover that any delusion prompted her to the act. In a case under outside care the patient would carry out various business transactions, receiving money, and paying it out, only later to find herself in her room without the slightest recollection of the acts performed.

As shown in the study of these cases, the prognosis is unfavorable. Under proper care, however, much improvement can be achieved. It is certain that the routine of asylum life, with the regular occupation, exercise, and uniformity of diet, has a favorable influence. The bromides given in sufficient doses will diminish the frequency of seizures very considerably. In the maniacal seizures, hyoscyamine, with or without morphine, hypodermatically, is to be recommended, or chloral in large doses during the periods of excitement, and especially is this advisable at the menstrual periods. As in epilepsy, the patient should be kept constantly under the influence of the bromides, except in cases in which the attacks occur only at long intervals; and while the administration of the bromides and chloral cannot prevent the attack at the period of its onset, it is advisable following the seizure, so as to insure or prolong the tendency to sleep that follows the exhaustion consequent on the explosion of nerve-force. Clouston states that he was able to reduce the attacks to one-sixth of their usual number, while the nervous and mental irritability and tendency to violence were also diminished. My personal experience has convinced me that the bromides, when sufficiently diluted, are well borne, and that the tendency is to bear them better as the length of time of administration increases. In only a comparatively few cases did evil results ensue. After many trials borax has failed in my hands. Nitro-glycerin, in conjunction with the bromides, especially in the *petit mal* type, is certainly of service. The diet should be a mixed one, and while restricting the consumption of meat I have not found it of advantage, either in hospital or private practice, to cut meat off altogether. Occupation, physical and mental, is of great importance. The patient's time should be employed. Operative interference, unless a definitely localized lesion can be diagnosticated, is not warrantable, and even in such cases other changes have occurred, if the course of the disease has become chronic, that render any likelihood of improvement improbable. Since the foregoing was written one of the patients in the list has been operated on, and I will incorporate his history:

A., thirty years of age, received an injury at the age of two years, on the right side of the head, over the motor area, since which time he gives a history of epileptic seizures, commencing on the opposite side, and becoming general. Examination reveals a marked depression in the skull, over the motor area, some paresis of the left upper and lower extremities, with exaggerated reflexes. The attacks occur almost daily; the patient is partially demented, and given to excessive masturbation. The operation consisted in the removal of a large area of the skull. The dura, pia, and cortex appeared normal to the eye, although the pulsation on this half of the brain seemed somewhat restricted. The patient made a good recovery, and his general health seemed improved. The attacks were at first reduced in number, but later resumed their usual frequency. The

only change observed was that the patient became very religious, constantly reading his prayer-book, and also inclined to steal anything he could lay his hands on, without regard to its value or usefulness to himself. These latter symptoms, of themselves so very common among epileptics, had not previously been observed.

It would seem, then, that the mental deterioration had been hastened rather than checked. Notwithstanding the failure in this case, I would indorse the operation in children, especially in cases of cerebral hemiplegia with epilepsy and imbecility. I believe that the earlier the operation is performed the greater is the chance of improvement, especially in cases in which the disease is due to cerebral compression from a tedious or forceps delivery, or following an injury, or after the exanthematous fevers. This is a new field, and the results so far have not been very favorable, but the generally hopeless character of the cases warrants considerable experimental investigation, based of course on scientific grounds.

I do not suppose that any new statement has been made in the record of these cases, and their interest lies chiefly in the observation of so many, with an attempt at classification of the mass of symptoms that they presented.

WHO CAN BE MEDICAL EXPERTS?

By HENRY A. RILEY, Esq.,
of New York.

The importance of medical evidence is acknowledged by all writers on jurisprudence and by everyone who is conversant with the profound problems that often come before courts of justice for solution. The trustworthiness of much of the so-called expert evidence that is brought out, even in the most famous trials, is not, however, so apparent and so readily acknowledged.

There is no doubt that a strong prejudice exists among the members of the bar and the judges themselves against such evidence, and the public press frequently expresses the contempt which the common people have toward this kind of evidence. Even among physicians themselves it seems certain that there is great dissatisfaction with medical expert evidence as we see it exemplified to-day on the witness-stand.

Some of the adverse opinions expressed by judges are ill-considered and unjust in the extravagance of their condemnation; but the statement of Justice Grier of the United States Supreme Court is no doubt held by many others. He says: "Experience has shown that opposite opinions of persons professing to be experts may be obtained to any amount; and it often occurs that not only many days, but even weeks, are consumed in cross-examinations to test the skill or knowledge of such witnesses and the correctness of their opinions, wasting the time and wearying the patience of both the Court and the jury, and perplexing instead of elucidating the question involved in the issue." Justice Stephen, whose recent retirement from the English Bench has deprived it of one of its most learned judges, gave utterance, in the celebrated trial of Mrs. Maybrick, to one of the severest criticisms of recent years. He even flippantly quoted the old saying which described a doctor as "a man who passed his time in putting drugs, of which he knew little, into a body, of which he knew less," and said that the fact that a learned man came into court and "swore to this, that, and the other, did not by any means give a reason for unqualified belief in what he said."

On the other hand, many judges have expressed their high opinion of the great help afforded courts and juries by the carefully considered and impartial statements of scientific experts, who have a thorough knowledge of the technical points involved, and no less an authority on evidence than Best has given his opinion as follows: "It would not be easy to overrate the value of the evidence given in many difficult and delicate inquiries, not only by medical men and physiologists, but by learned and experienced persons in various branches of science, art, and trade."

In fact, it would be impossible for juries to give any intelligent verdict in many civil and criminal cases if it were not for the clear and convincing testimony of medical experts. Take, for instance, the recent trial of "Frenchy" in New York City for the murder of the woman called "Shakespeare," in which it would seem that medical expertism had shown a decided advance. In this case the conviction very largely hinged upon the chemical analysis of the contents of the woman's stomach and intestines, and the comparison with scrapings from the clothes and fingers of the accused man.

There is clearly no doubt that scientific witnesses will be required in the future, as in the past, for the elucidation of doubtful technical points, and it becomes a very important question to know who can be received as medical experts. Such persons have had a recognized position in the English witness-box for hundreds of years, and it was the eminent jurist Coke who pronounced the judgment, *Cuilibet in sua arte perito est credendum.* The propriety of this prohibition to all who are not skilled in their profession has been abundantly verified in the course of litigation since his time, and the ignoramus or the charlatan that ventures to air his opinions only brings disgrace on himself and his profession. Dr. Elwell, in his well-known work on *Malpractice, Medical Evidence, and Insanity*, says in regard to this matter: "While but little, compara-

tively, is expected of timid ignorance or weak and trembling inexperience, much, very much, is rightfully required and looked for from the learned and public man. If the former are able to command presence of mind and language sufficiently intelligible to be understood, it is as much or more than is expected of them. Not so, however, with the man of public and professional pretensions. He is measured properly by a different and more exact and rigid rule. If he fails to furnish good measure, he will most certainly leave the stand disgraced, and his friends chagrined and disappointed. There is no situation, perhaps, where the professional medical man can be placed wherein he will be subjected to a more thorough, rigid, and severe criticism as to what he says, how he says it, and the reason why he says it, with all the influences that may have a bearing on what he says, than as a medical witness in a court of justice, under the eagle eye of an able judge, the severe and interested scrutiny of counsel, and the candid and impartial observation of a jury. This is not only forcibly true as to the position of the medical witness, but is almost savagely so. On the one hand, the party by and for whom he is called seems to expect that he will say nothing that will damage him; that the weight of his character, professional reputation, position, influence—everything will all go to favor his interests; while, on the other hand, this very weight of character, influence, etc., will arouse the resisting energies of the opposite party to contradict, break down, and destroy the effect of such testimony. An important witness thus placed between two fires, as it were—a conspicuous mark as he is—will do well if he comes off without being badly wounded."

The very title of expert seems to demand superior knowledge and a practical experience in his chosen profession, but courts have not always insisted on the possession of both practical and theoretical knowledge as a preliminary to giving testimony. A person may make himself competent to testify as an expert who has gained a special knowledge of the particular subject under investigation by the reading and study of standard authorities, and not from experience and actual observation. The expert must be educated by the science of medicine, but his knowledge may have been obtained by study without practice, or by practice without study, if that is possible. In other words, unless there is a statute in the particular State to the contrary, the expert has only to make his knowledge evident, the source from which it was obtained not being material.

The rule has been broadly stated as follows: "It is not necessary that he should be a physician or have studied for one, nor be a graduate, nor one licensed to practice, nor need he have been a practitioner" (Rogers on *Law and Medical Men*, p. 111). This general rule has been somewhat modified by decisions in the various States. In Vermont (Fairchild *vs.* Bascomb, 35 Vt., 410) it has been held that mere education as a physician, without some practice as such, is insufficient to qualify one as an expert, and in Arkansas (Polk *vs.* State, 36 Ark., 117) competency must be shown both from study and experience. In New York (Roberts *vs.* Johnson, 58 N. Y., 613) a physician not in active practice at the time may give expert evidence, but this fact will tend to affect his credit. In general, it may be said that a person who has not become a physician by the ordinary methods of graduation and licensure, or who, not being a physician at all, attempts to give expert evidence, will have little weight given to his testimony, even though he may gain admittance to the witness-stand. A person cannot qualify himself as an expert in a particular case merely by devoting himself to the study of authorities for the purposes of that case, when such reading and study is not in the line of his special calling or profession, and is entered upon to enable him to testify in the case.

An illustration of the rule that the expert need not be a physician is seen in a California case (*Re* Toomes, 54 Cal., 575), where a priest who had made a special study of physiology and psychology in order to be able to judge of the mental conditions of the communicants in his Church, and had experience daily in this way, was allowed to give an opinion of the mental state of a woman whom he had attended in her last illness.

The cases are rare, however, where a person who has not passed through a regular course of medical training is allowed to testify as a medical expert, and few lawyers would venture to place such a person on the stand, knowing what a merciless attack would be made upon him by the opposing counsel, should it appear that the so-called expert had not received the best instruction on the subject he claimed to give information about. So decided is this tendency toward requiring the most comprehensive knowledge on the part of the expert that specialists are usually called when a particular point in medical science is to be elucidated. This is not, however, a necessary requirement, as general practitioners are assumed to have sufficient knowledge to testify upon questions that are strictly and legitimately connected with their profession. Thus, one not an oculist can give an opinion in regard to injuries to the eye (Castner *vs.* Sliker, 33 N. J., 97), and one not an alienist can testify in regard to insanity (State *vs.* Reddick, 7 Kan., 143).

If the witness is not a specialist, however, his opinions will be received with less weight than if he were an acknowledged authority in the more limited

branch of medical science. There are some decisions that trend in the opposite direction, but they are not numerous, and show that special circumstances served to sway the court. Thus, in Vermont, a physician who for more than thirty years has devoted his attention almost exclusively to the treatment of insane persons cannot be permitted, as an expert, to testify to the mental capacity of a person not previously insane, but in the last stages of disease (Fairchild *vs.* Bascom, 35 Vt., 398). In Massachusetts a physician who has not made the subject of insanity a special study, and who, when his patients require medical treatment for insanity, is in the habit of calling on a physician who makes insanity a specialty, or recommending the removal to an insane asylum, is not competent to give an opinion on a hypothetical case put to him (Com. *vs.* Rich, 4 Gray, 335, 337).

When the question of the possession of special knowledge sufficient to entitle a person to testify as an expert is under consideration, the standard of qualification required by the court will vary in different localities. Thus, in a case tried by a judge in a country district distant from the large cities, the same high standard of special knowledge would not be required as in the cities of New York or Philadelphia. An interesting case involving this point was decided in Iowa over ten years ago, and merits quoting quite at length. In this case the defendant was charged with poisoning his wife by means of strychnine, and the judgment of the court was as follows: "Two physicians were called, and testified as to the tests applied in the chemical analysis made of the stomach of the deceased, and also of the tests usually applied for detecting the existence of poison in such cases. Both of them testified that they were practising physicians. One of them stated that he was not a professional chemist, but understood some of the practical details of chemistry—that portion at least which pertained to his profession—that he had no practical experience in the analysis of poisons until, in connection with Dr. Francis, he analyzed the contents of the stomach of the deceased; that since that time he had conducted experiments on a small scale; and that he was previously acquainted with the means of detecting poisons, and had since had some experience in that way. The other testified that he was not a practical chemist; that he did not follow the science as a profession; that he understood the chemical tests by which the presence of strychnine can be detected; that he professed to understand the principles of chemistry as laid down in the books on that science; that he never experimented with a view to detect strychnine by chemical tests; that he had seen experiments by professors of chemistry; and that there was one test much relied on, the trial of which he had witnessed. Defendant objected to these witnesses as incompetent, and now urges that they did not show themselves possessed of the requisite professional skill.

"We think they were competent witnesses. It is, of course, desirable that great caution should be exercised in conducting experiments of this character, and that the most skilful professional aid should be secured. If conducted, however, by such as have not had experience, or by those who, though not practical chemists, give their opinions from knowledge derived from the books upon that science, such opinion would be entitled to less weight than if given by a practical chemist—he who bases his conclusions upon experience as well as books. The means of knowledge are proper to be considered by the jury, and they should give or withhold credence in the opinion given as they may believe the expert qualified to speak more or less intelligently and understandingly. But to say that none shall be permitted to give their opinions except those of the highest professional skill, or those who have given their lives to chemical experiments, would, in this country at least, render it impossible in most cases to find the requisite skill and ability."

In a case decided in Alabama (Washington *vs.* Cole, 6 Ala., 212), a physician stated in his deposition that he attended a negro "as a physician," and it was held that this was sufficient evidence that he was a physician to warrant the admission of his opinions in evidence regarding the disease of the negro.

An important point for consideration is how the question of the possession of sufficient knowledge to entitle a person to testify as an expert is to be decided.

This is a matter of fact to be decided by the judge, and not by the jury, and such decision will not be interfered with on appeal, except in a clear and strong case (Lorg *vs.* First German Congregation, 63 Pa. St., 156; Hills *vs.* Home Ins. Co., 129 Mass., 544–551).

If the proposed expert is not able to establish the fact of special knowledge or skill, he will not be allowed to testify, and the court may personally examine such witness in order to ascertain his qualifications, or may hear evidence on the point (Lester *vs.* Pittsford, 7 Vt., 161; Boardman *vs.* Woodman, 47 N. H., 121; Davis *vs.* State, 35 Ind., 496).

In one case in Indiana (Forgery *vs.* First Nat. Bank, 66 Ind., 123–125) the Supreme Court said: "We find no test laid down by which we can determine with mathematical precision just how much experience a witness must have had, how expert, in short, he must be, to render him competent to testify as an expert."

The court must exercise a fair discretion in de-

ciding on the qualifications of an expert, and from such a decision there is no appeal.

The courts do not allow the point that an expert belongs to a particular school or system of medicine to have weight in deciding his right to testify. The law does not recognize any single class of practitioners as alone entitled to be called "physicians," but all are equal (Corsi *vs.* Maretzek, 4 E. D. Smith, 1).

TRACTION AND FIXATION IN POTT'S DISEASE.[1]

BY REGINALD H. SAYRE, M.D.,
OF NEW YORK.

ONE of the fundamental principles in the treatment of all joint-diseases is, so far as possible, to secure the absence of traumatism. In the spine, traumatism may be caused, first, by movements of the diseased parts; second, by the weight of those parts of the body, when erect, that are above the point of disease; third, by jars, when walking; and last, by the reflex muscular spasm common to joint-disease wherever situated. This muscular spasm is an effort on the part of Nature to secure rest for the diseased joint, and when an apparatus, or the surgeon's hand, or any other means secures this rest, this reflex muscular spasm disappears. The care shown in the gait of patients with Pott's disease, and the frequency with which they support the weight of the upper part of the body by resting their hands on the seat of the chair, etc., point most clearly to the necessity of relieving the diseased spine from the superincumbent weight, and protecting it as far as possible from concussion.

Pott recognized the necessity for preventing concussion, and removing the weight of the upper part of the body, but the rest in bed that he advocated, though certainly very beneficial, gives but very imperfect rest to the diseased spine, as it does not prevent motion, or abolish reflex muscular spasm.

The addition of a posterior splint of metal or other material, fastened into position by straps around the shoulders, and an apron across the chest and belly, more or less completely prevents movement of the diseased joint, but is defective in not supplying traction to overcome the ever-present reflex muscular spasm. Another objection to this class of splints is that the trunk must be so tightly girdled, in order to give rest to the spine, that respiration is greatly impeded, and, in consequence, the nutrition of the patient suffers.

Pain is to my mind a symptom of irritation, and the relief of pain is a good index of the removal of the source of irritation. The means that gives the greatest freedom from pain most thoroughly removes the source of irritation and puts the patient in the best condition to recover.

In all joint-diseases, traction, in my experience, is a great reliever of pain, and I consider it a mistake to disregard it in the treatment of Pott's disease. I frequently see children insist on keeping the straps of their jury-mast so tight that it is very difficult to prevent galling of the chin and occiput from constant pressure, and yet these children beg to have their straps fastened again when they have been loosened to bathe the head, the pain caused by these chafes being so much less than that caused by the irritation of the spine when the traction is diminished. I have seen these same children, later on, when the inflammation of the spine was less acute, ask to have the straps of the jury-mast loosened, and, still later on, ask to have them removed altogether, the necessity for employing traction having passed by.

A patient of mine, an adult of great intelligence, with lumbar Pott's disease, who was confined to his bed for eighteen months prior to the application of a plaster-of-Paris jacket, has often spoken to me of the relief afforded by stretching his spine. I have seen him drive over rough pavements in his jacket, without the least pain, at a time when he was obliged to use the utmost caution in movement in bed with his jacket off. Some of the jackets I have made for him have failed to give relief, as they did not lift up the thorax sufficiently to protect the diseased lumbar spine, though they were adequate to prevent motion. He says that he is not comfortable unless the trunk rests in the jacket, and the weight is thus transmitted to the pelvis, without pressing on the diseased part of his spine. I cannot help thinking that the more effectually we remove the weight from the spine in all cases, the more efficiently we have protected the patient.

It is because they act by lifting off the superincumbent weight more effectually than other means that I prefer jackets passing completely around the body, to posterior supports, which act merely by preventing motion, and do not diminish concussion or lift off superincumbent weight, unless they are provided with jury-masts. Those that are provided with the latter are almost invariably defective in having no base of support on which the splint may rest, and are prevented from slipping down, when traction is made on the head, simply by the friction of the splint on the body. This friction is distributed both above and below the point of disease, and thus adds to the pressure made on the diseased point, which becomes greater in proportion to the extent to which the straps of the jury-mast are tightened. In a badly-fitting plaster-of-Paris jacket the same trouble appears, and I have seen numbers of plaster jackets the jury-masts of which were fitted with

[1] Read before the American Orthopedic Association, Washington, September, 24, 1891.

pads under the joint where the crossbar was riveted, with the purpose, I suppose, of preventing injury to the head when the jury-mast rested on the child's crown. It is obvious that a child carrying a jacket of this kind receives no benefit from traction, but simply carries around on its inflamed spine the weight of the jacket and jury-mast, in addition to the weight of that part of its body that lies above the point of disease.

In upper dorsal disease, the point of inflammation is too high for the jacket to exercise sufficient control over movement, and for this reason I think that jackets are inferior to posterior metal supports fitted to pelvic belts that have bands passing above the crests of the ilia to form a base of support, so that traction by a jury-mast may be effective. In addition to this, there should be curved metal bars passing from a plate that rests against the scapulæ under the axillæ to the front of the shoulder, where padded metal plates should make pressure, in order to prevent the shoulders from dropping forward, and thus causing the chest to sink in.

Straps passing around the shoulders are not effective, and the point of pressure in front must be the head of humerus.

In cervical disease, also, if there be no time to have a suitable metal one made, the jacket is useful merely as a base of support for the jury-mast.

In lower dorsal and lumbar disease, however, for the reasons that I have mentioned, I think that jackets enveloping the body are more effective in giving rest to the inflamed area than posterior supports, as the latter exercise no upward traction, but simply bend the body backward, making a fulcrum of the posterior part of the spine opposite the point of disease, which they endeavor to separate, in the same way as a hinge is opened.

The more accurately a jacket fits, the better, and hence I prefer those made on the patient to those made over moulds made from the patient's jacket, as the second one is not so sharp in outline as the first, and, in small, skinny children it is often very difficult to get accuracy of fit, especially when there is great deformity. Very little changes make the difference in having a jacket that will not slip over the hips, and one that will so slide when the jury-mast is tight. For making the original jacket on the patient, I have found nothing so satisfactory as plaster-of-Paris.

In closing, I would say that if, because of sores or because the ilium is too small to afford a base of support, the case is not suitable to be treated in a jacket, I believe traction in bed by head-straps and weight and pulley, or by elastic, or, better still, by means of the portable wire cuirass, should be used, and, in all cases of paraplegia in Pott's disease, I would make faithful trial of traction and counter-irritation before proceeding to resection of the laminæ.

In making traction, I should be guided by the feelings of the patient. To use my father's words when he introduced plaster-of-Paris jackets seventeen years ago: "Raise the patient until he is comfortable; there stop, and keep him so."

SO-CALLED STRUMOUS INGUINAL LYMPHADENITIS.[1]

BY L. T. RIESMEYER, M.D.,
OF ST. LOUIS, MO.

THE pathology of the chronic forms of inguinal lymphadenitis is still a disputed question. I incline to the view of Culvert (Eulenburg's *Encyclopedia*) and Klotz (*Berlin. klin. Wochenschr.*, 1891), that the majority of cases known under the names of strumous buboes, indolent sympathetic buboes, hyperplastic lymphadenitis, etc., are caused by the absorption of pyogenic material and are not due to scrofula, tuberculosis, or syphilis. Of forty-three cases that I have observed, the majority had suffered from gonorrhea from six months to five years before they presented themselves. Three patients had chancroids, and one also a syphilitic chancre, a number of months before they came to be treated for the lymphadenitis. In five cases the swelling in the groin was attributed by the patient to the lifting of a heavy load, while for the rest no cause was ascertainable.

As a rule, the patients came during the later stages of the disease and presented the following symptoms: Face pale and ash-colored, loss of appetite, a tired feeling, pains in the limbs, chilly sensations alternating with sensations of heat, night-sweats. Temperature varying between 100° and 102° F.

Upon examination a large, nodular tumor, irregular in form, often fluctuating at one or more points, is found in one or both groins. The skin covering the tumor is, in contradistinction to the virulent bubo, of a livid, blue color, and is not infrequently perforated by one or more fistulous tracts. There is usually but little pain upon pressure. *In all cases the glands contained a great many miliary abscesses*, otherwise showing only a hyperplasia of the connective tissue and the medullary lymphatic tissue. Of microörganisms, staphylococci and streptococci were found. Hypertrophied lymphatic vessels run over and through the substance of the tumor. In some cases the glands presented one large fungous mass, in which no individual gland could be made out. The time required for the development of the tumor as described varied between six months and three years. No tuberculosis was found among

[1] Abstract of a paper read at the meeting of the Mississippi Valley Medical Association at St. Louis, Mo., October 14, 1891.

the cases and after the operation the patients presented a strong and healthy appearance. Strict antisepsis or asepsis is necessary in the extirpation of the glands, on account of the important structures in the neighborhood of the inflammatory focus. If the glands are not removed before the pus has broken through the capsule, the patients are exposed to the following dangers: hemorrhage and gangrene, in consequence of erosion of the femoral vein; deep abscesses of the thigh and pelvis and retroperitoneal abscesses; coxitis and gangrene of the scrotum, peritonitis, septicemia, and pyemia.

In one case serious complications were observed, namely, a deep abscess of the thigh, a pelvic abscess, and very extensive gangrene of the scrotum. The whole anterior half of the scrotum and part of the septum sloughed away, and for two weeks the temperature varied between 101° and 105° F. Three years later the patient was well; he had no inconvenience from cicatrical contraction of the scrotum, although no plastic operation or skin-grafting had been done, showing that the loss of one-half of the scrotum may not necessitate a plastic operation.

To extirpate the glands, the method recommended by Poelchen (Langenbeck's *Archiv. für klin. Chirurg.*), of first exposing the internal saphenous vein by a vertical incision and dissecting along this vessel, leaving it intact upon the fascia lata, is the most rational. The glands are in this way removed quickly and without endangering the femoral vessels. In conjunction with Dr. L. P. Pollmann, I have had occasion to locate this vessel topographically. After determining the location of the femoral artery in the usual manner, the internal saphenous vein is found exactly at the point of union of the external with the middle third of a straight line connecting the pubic spine with the point of intersection of Poupart's ligament with the femoral artery.

MEDICAL PROGRESS.

Operative Treatment of Traumatic Cortical Epilepsy.—BENDA (*Deutsche medicin. Wochenschr.*, September 3, 1891), before the Congress of German Surgeons, reported the case of a soldier, twenty years old, with no neurotic family history, who, a year and a half after a fall from a horse, attended with injury in the left parietal region, suddenly, while at work, lost consciousness. Subsequently there developed headache and pain, referred to the cicatrix of the previous wound; then apathy and weeping. These manifestations augmented in intensity, until finally syncopal and hysterical attacks occurred. Four months later, an epileptic seizure of several hours' duration took place, followed in the succeeding four days by four lesser seizures. Several days later, the paroxysms assumed a characteristic type, which they retained thenceforth. The attack began with tremor in the right foot, succeeded by clonic spasm in the right leg, tonic contraction of the right arm, and finally feebler contractions on the left side, and was followed by hemiparesis of the right side. Hysterical attacks alternated with the attacks described. Ultimately aphasia frequently became associated with the hemiparesis. Mental and physical failure progressed and permanent monoplegia of the right leg developed. Nearly two years after the accident, trephining was performed, the dura mater opened, and by means of the faradic current the center for the right leg localized. From this region an area of cerebral tissue, about as large as a dime and about one-tenth of an inch thick, was removed. The pial veins in the arm-center were ligated, the wound packed with iodoform-gauze and at the end of two days sutured and drained. The subsequent course was uninterruptedly favorable. After the operation, the right arm was paralyzed, the right leg to the knee paretic. Two weeks later, the palsy of the right arm suddenly disappeared. Nearly three months after the operation, an hysterical seizure occurred, induced by anger. Subsequently, however, there were no further indications of hysterical or epileptic attacks. Intelligence returned and mental occupation became possible. Slight motor weakness of the right arm, and a feeling of numbness at the right costal arch, the right knee and the ulnar side of the right ring-finger were the only abnormal clinical evidences that finally remained.

A Bullet in the Skull for Forty-three Years.—SAXER (*Corresp.-Blatt f. Schweizer Aerzte*, September 15, 1891) reports the case of a soldier who, when twenty years old, was struck by a bullet in the region of the left mastoid process, the missile perforating the bone and remaining unextracted. The patient lived for forty-three years after the reception of the injury. For twenty years a sinus persisted, the wound suppurating moderately. The patient complained of pain and a sense of weight and boring in the head and noises in the ears; there were mental confusion, impairment of memory, and other psychical symptoms. At the autopsy the flattened bullet was found imprisoned between the dura mater and the bone, in the midst of an inflammatory hyperplasia, behind and below the pervious defect in the bone. There was a permanent depression at a corresponding point in the left occipital lobe.

Ossifying Myositis.—MACDONALD (*British Medical Journal*, August 29, 1891) reports the case of a girl, four years old, in whom at two years of age hard nodules developed in numerous muscles of the head, neck, upper extremities, and trunk, occasioning rigidity and interfering with the movements of the affected parts. No hereditary factors could be elicited. Treatment was of no avail. Portions of the indurated parts removed were constituted of bone, having fibrous attachments of origin and insertion.

Kerauno-Neuroses.—FRANKL-HOCHWART (*Zeitschr. f. klin. Medicin*, Bd. xix, H. 5 u. 6, 1891) describes as kerauno-neurosis a condition that develops in persons who have been struck by lighting. The symptoms are those characteristic of the traumatic neuroses, and include palsies, tremor, derangement of common and of special sensation, limitation of the visual fields, ataxia, and exaggerated reflexes.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment. When necessary to elucidate the text, illustrations will be provided without cost to the author.

Address the Editor: GEO. M. GOULD, M.D.,
1004 WALNUT STREET,
PHILADELPHIA.

Subscription Price, Including Postage in North America.

PER ANNUM, IN ADVANCE . . . . . $4.00.
SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, NOVEMBER 14, 1891.

IDIOSYNCRASY.

THE strange phenomena connected with idiosyncrasy serve but very dimly to light up the gloom of the chasms of our ignorance of physiological processes. We look with wonder into the depths and shudder that at last we know so little as to the ultimate constitution of protoplasm, the nature of nutrition, and the *modus operandi* of toxic substances. The writer knows a family of which the female members for several generations have been unable to eat strawberries without genuine and decided symptoms of poisoning ensuing. The male members of the family eat them as others do, but a single berry given by a disobedient nurse in a few hours killed a little daughter of two years. DEJEAN says that the celebrated HACHU was thrown into convulsions whenever he dared to eat strawberries.

Probably the most remarkable case of idiosyncrasy on record is that of DAVID WALLER, described in detail by DR. OVERTON in the *Southern Journal of the Medical and Physical Sciences*, vol. iii., 1855. In all other respects than that to be described, Waller was a healthy, normal man, born of healthy parents. Seven brothers and sisters were free from his idiosyncrasy, and his own seven children were also free from it. But to this poor man life became almost unendurable because for him wheat flour was poison. Unbelieving friends would deceive him, and put a pinch of flour into his food. Trusting them, he would eat, but the violent toxic symptoms never failed to follow. DR. OVERTON thus describes the peculiarity:

"If he eat flour in any form, or however combined, in the smallest quantity, it produces in two minutes or less, painful itching over the whole body, followed soon by severe colic and tormina in the bowels, great sickness of the stomach, and continued vomiting, which is ten times more distressing than that produced by tartar emetic—the itching is more greatly increased in violence, and especially of the head, face, and eyes, but tormenting all parts of the body, and not to be even appeased by any degree of scratching, or any other means ever used for the purpose; the eyes also burn painfully, turn very red, and discharge much water. And these latter symptoms occur usually in about ten minutes after eating the wheat flour, no matter how prepared—the sickness of the stomach preceding the other symptoms.

"The above symptoms continue for two days with intolerable violence, causing great torment, and begin only to decline in severity on the third day after the attack; and usually cease after ten days' continuance. As the foregoing symptoms begin to decline in violence, the effect of the poison appears to seize upon the lungs, causing much and distressing cough, soreness, and making the lungs feel rough from coughing, causing a feeling of suffocation, and the expectoration of a great quantity of phlegm. Toward the end of the attack the symptoms are like those of a person laboring under consumption, and have often caused him alarm, and to fear that they would terminate in that disease. The attack produces great weakness, confines him to his room, and most of the time to his bed, in which he is often obliged to be propped up to aid his breathing, which is difficult and laborious, like a person afflicted with asthma. Except during the few first days of an attack, the appetite is not greatly impaired.

"The smell of wheat flour produces all the above symptoms in a minor degree, except sickness at the stomach, vomiting, and pains and tormina of the bowels. It is for this reason that he cannot go into a mill, or house, where the smallest quantity of wheat flour is kept, without suffering; the smallest amount, if loose, is sure to be smelt, and, if not immediately escaped from, to produce upon him the painful effects before stated.

"This has been his condition from the time of his earliest recollection, and his mother has told him that when an infant at the breast, he had been laid out as dead, caused by feeding him with pap that was thickened with wheat flour."

MR. WALLER'S own explanation of this strange fact was that during gestation the family having no flour the mother's longing for wheat bread was intense, and when it was obtained and eaten it made her violently sick, and caused her to loathe such bread for some time afterward.

Shell-fish—crabs, lobsters, clams, mussels—pro-

duce cholera-morbus in a certain proportion of persons. DR. HYDE SALTER (*Edinburgh Medical Journal*, May, 1859) describes two cases in which a few grains of rice or rice-flour, however surreptitiously introduced into the food, speedily produced the greatest distress with asthmatic symptoms. Instances are on record in which figs have caused illness; eggs, swelling of the tongue and throat, and alarming sickness; veal, a nettle-rash; and it is well known that to many persons honey is almost or quite poisonous. Meat of any kind will in some persons produce violent pain, nausea, and vomiting. Vinegar will in certain patients cause cholera-morbus, and in others salad-oil will result in a cutaneous eruption all over the body. There seems to be no article of food that in certain individuals will not produce toxic symptoms, whenever eaten—even milk being a powerful gastro-intestinal irritant to some children.

There is even a greater chronicling of illogical and anomalous facts as regards drugs. One person will be mercurialized by a grain of blue mass, while another will take ten grains every day for a week without symptoms. One-thirtieth of a grain of morphine will sometimes produce decided physiological effects in some patients: in one acting as a hypnotic, in another as a stimulant. Five grains of potassium iodide have been sufficient to bring a patient to death's door. Toxic symptoms have been caused by $\frac{1}{400}$ of a grain of conine hydrobromate. A case was reported last year (*Amer. Journ. Med. Sci.*) in which enormous swelling of the tongue followed small doses of antipyrin. HARGENS had a patient who was repeatedly salivated by small doses of opium; WERNER reports a patient in whom violent emesis always followed the administration of the drug, and in GAUBIUS'S patient it produced a general desquamation of the epidermis.

If one seek for a satisfying explanation of the phenomena of idiosyncrasy in the books, he will seek in vain.

We begin to catch glimpses of reasons in the different reactions of various orders of animals to specific substances. Hogs are very resistant to snake-poison, graminivorous animals have a remarkable indifference to atropine, etc. In the facts of immunity, however, we get a deeper insight into the mystery, and in the selective action of different drugs upon special tissues of the body we seem to be yet nearer the truth.

It doubtless seems to have no logical connection with the foregoing to mention the simple but patent fact that every person exhales an odor different from that of every other person in the world. A dog, by smelling, can tell his master's footstep from that of every other person. Thus it follows that the atomic and molecular constitution of the general protoplasmic molecule is different for every individual. The selective action of drugs upon the various organs of the body proves the further differentiation of protoplasm in these different organs. The ultimate molecule of nerve-cells, of nucleoplasm or bioplasm, is the most complex of substances, formed of the greatest number of constituent atoms, and necessarily in a condition of the most unstable equilibrium. A touch or jar breaks off loosely-held component parts, and at the approach of a foreign intruder it readily yields them up, as they are caught in the more powerful sweep of the stronger vibration. It is upon this combined complexity and instability that depends the entire function of the release of energy, the conversion of molecular into mechanic force. The peculiar constitution of the protoplasmic molecule, ever varying and continuously changing, depends for the individual and for the organ upon the individual history and the special nutritional habit, inherited or acquired, and in each one it must therefore react in a different way to the same influence. Every molecule is an enormously complex system of systems of multiform subordinate vibrating atoms held loosely by the carbon sun to a common center. Powerfully modified in structure by a peculiar habit or experience, the molecule resists change by a neighboring alien or toxic system that would steal its peripheral comets or Neptunes. We thus catch a hint of the explanation of the fact of immunity. Or, again, by denial of accustomed nutrition the molecule may become so abnormally modified and permanently self-compensatory that the simplest nutriment may disrupt the delicate bonds, and what was once the best of foods become now the most potent of poisons.

PULMONARY TUBERCULOSIS AND MALARIAL FEVER.

THERE is probably no mistake in clinical medicine so common as that of confounding pulmonary tuberculosis and malarial fever. The latter is not often mistaken for the former. Though no harm might result, the error would still be a culpable one. But careless observation and criminal want of physical investigation have unfortunately in too many cases led to a diagnosis of malarial fever when a grave

disease of the lung existed. In such a case the error would be a fatal one, especially in view of the relative success with which, in judicious hands, cases of incipient tuberculosis are treated. "Malaria" has been made to serve as a diagnosis in many an obscure and anomalous febrile condition, but in no single one more disastrously than in pulmonary tuberculosis.

There is a period in the history of tuberculosis of the lungs when there may be reasonable diagnostic doubt, but a little patient waiting, with *careful observation, thorough physical exploration*, judicious therapeutics, and above all *examination of the blood and of the sputum*, in accordance with modern scientific methods, will set all doubts at rest. There can be no excuse for error, if any of these means of diagnosis are neglected.

The greatest difficulty, however, is encountered in cases in which, on repeated investigation, neither the evidences of tuberculous disease of the lungs are to be detected in the sputum nor the evidences of malarial disease are to be detected in the blood. In such cases importance is to be attached to the family history, to the hygienic surroundings, to the symptoms, and to the course of the disease, and, finally, to the results of treatment. Negative evidence can never be so valuable as positive evidence. Then there are other cases in which malarial infection is only too evident, but in which observation and examination would disclose the simultaneous existence of tuberculosis of the lungs. In the light of increased knowledge we can no longer maintain that malarial disease and tuberculous disease cannot coëxist.

The lesson to be derived from all this is, that the practitioner dare never, in any case, permit the possibilities of combination to escape him. In all obscure cases every line of investigation must be pursued to its ultimate refinements, and not an organ or system should escape the closest scrutiny. The medicine of the future must be alert, anticipating disease, preventing its development when possible, and stamping it out in its incipiency.

THE KEELEY CURE.

People seem never to tire of chicanery and humbug. Mystery and quackery naturally go hand in hand, and the remarkable, almost inexplainable love of humanity for the adept professors of these twin arts will always furnish a plentiful supply of dupes. So great is the curse of drunkenness that if by the humbuggery of secrecy, delusion, and hypnotic suggestion, any considerable proportion of drunkards could be reformed, it would almost appear inexcusable to make light of the chicanery, and the expert trickster might pocket his million in undisturbed peace. But a knowledge of Nature's laws and of the facts of physiology leads one to recognize that revulsion and evil finally result from trifling with moral or physical facts. It is in the long run better to cure rightly and really than wrongly and delusively. The doing of evil that good may come is pathologically and therapeutically prone to be resultless of good.

Concerning the so-called bichloride-of-gold treatment of drunkenness, it may be suggested that bichloride of gold does not exist in stable solution. Our modern Cagliostro should know that the compounds of chlorine and gold are either the monochloride or the trichloride. He should, therefore, devise a new chemistry, or adopt a proper nomenclature.

There can be no discussion of the heinousness of the crime of advertising the possession of a remedy for drunkenness, and at the same time keeping the nature of the preparation or treatment a secret. If ever the use of thumb-screws and rack were justifiable they should be applied to the wretch that for purposes of gain would keep from humanity the knowledge of such a cure.

The medical profession, so far as its self-respecting members are concerned, has set its face rigidly against secret nostrums, and despite all the cry of bigotry and prejudice that may be raised by the unthinking mob of magic-mongers, there will be no compromise upon the question while there remain in the profession honor, love of fellow-men, and hatred of disease.

SOCIETY PROCEEDINGS.

NEW YORK STATE MEDICAL ASSOCIATION.

Eighth Annual Meeting, held in New York City, October 28, 29, and 30, 1891.

(Continued from p. 555.)

Second Day—October 29th.

Dr. F. M. Warner, of New York County, read a paper entitled "Notes on the Treatment of Tuberculosis." Speaking of heredity, he said that the weight of authority was with those who believed that tuberculosis in very young infants was acquired by the ingestion of milk or other substance infected with tubercle-bacilli. What was inherited was a suitable soil for the development of the bacilli. Referring to prophylaxis,

he spoke particularly of the danger to the public health from lack of attention to the proper cleansing and disinfection of railroad cars. He detailed the histories of nine cases that he had treated with Koch's tuberculin, most of which showed decided improvement, two being apparently cured. The antiseptic treatment of pulmonary tuberculosis by inhalations of creasote and terebene, and the internal administration of creasote, had resulted in a marked diminution of cough, but had not arrested the progress of the disease.

DR. CHARLES W. BROWN, of Washington, D. C., read a paper on "Dislocation and Fracture of the Vertebræ," in which he expressed the view that in the treatment of these conditions the most important point is to immediately etherize the patient, and endeavor to reduce the dislocation by extension and manipulation, or by bending the spine across the knee as a fulcrum; and if these efforts proved ineffectual, to cut down upon the vertebra, effect the reduction, and remove any fragments of bone that were likely to become necrotic, or that were found to be pressing upon the cord. Careful studies, both clinical and pathological, showed that, after division of the cord, union is not likely to occur under any treatment. Of 123 recorded cases, 84 were cervical, 30 dorsal, 7 lumbar, and in 2 the location was not stated.

DR. DOUGLAS AYRES, of Montgomery County, read a paper entitled "Two Cases of Forward and Outward Dislocation of the Astragalus, with Mode of Reduction and Result," in which he expressed the view that it is not possible to formulate an exact course of procedure applicable to all cases of luxation of the astragalus, owing to various complications that may arise; but in the two cases reported, which were apparently typical, the prominent factors in bringing about the desired result were complete anesthesia, thus insuring perfect relaxation of the parts, and taking advantage of the best position to make extension and to graduate the force required.

DR. J. W. S. GOULEY, of New York County, exhibited a plaster cast that had been taken a few hours after the occurrence of a forward and outward dislocation of the astragalus. The cast showed well the prominence of the head of the astragalus upon the instep. Dr. Gouley also presented a patient who had received a similar injury a month previously. The case was admitted into the hospital a few hours after the accident, and an immediate attempt at reduction by means of manipulation with the hands was made, carefully avoiding the use of very much force. By flexion, extension, and a little rotation, a few minutes of such manipulation sufficed to effect the reduction. The leg was then enveloped in cotton and a snug bandage and an outer wooden-splint were applied. At the end of a week a gypsum bandage was applied, and after eighteen days this was removed and the patient allowed to walk around. The application of excessive traction by means of pulleys or other similar apparatus, is much more likely to do harm than good. The great point is to effect the reduction within a few hours after the injury, and to do this without the employment of much force.

DR. E. M. MOORE, of Genesee County, emphasized the inadvisability of employing much force in the attempts at reduction. He pointed out the importance of placing the splint at right angles.

DR. HOMER O. JEWETT, of Cortland County, exhibited some rat-tailed larvæ that had been voided from the human intestine in two different cases, together with carefully prepared histories.

DR. A. L. CARROLL stated that, with the aid of another entomologist, he had been able to determine that these larvæ belonged to one of two species of dipteræ—either meseron or eristalis. Their exact place could only be determined by examining the fully developed insects. Although several similar cases are on record, these are the best observed that have been reported. Very few physicians are aware of the comparative frequency with which these pseudo-parasites infest the human subject. It has been supposed that the larvæ are carried into the human stomach by drinking-water or uncooked vegetables, such as salad.

DR. S. T. CLARK, of Niagara County, presented a case of rupture of the diaphragm at the antero-posterior angle of the esophageal orifice, with consequent laceration of the branch of the phrenic artery that passes through the diaphragm at the corresponding point, and disturbance of the accompanying phrenic nerve. While lifting a heavy weight the patient was seized with a sharp, transient pain, referred to the extremity of the ensiform cartilage, and followed by nausea, pallor and great prostration. A small clot of blood was probably formed at this time, which accounted for the temporary amelioration in the symptoms. Two hours later, when the stomach was fully distended with food and the conical portion of the esophagus was distended by the disengaged gases, the lacerated surfaces were more fully separated, permitting a recurrence of the hemorrhage, with a corresponding augmentation of the pallor and nausea, to which diaphoresis was added. Shortly after, under similar circumstances, the same symptoms appeared with increased severity. On the following day the accumulated clots filled the anterior portion of the middle mediastinum, and crowded the heart an inch and a half to the left. A week later the clots had so far become absorbed as to permit the heart to resume its normal position and action. A slight pericardial friction-sound was heard at one time; this was interpreted as indicating that there was a partial organization of the clot at the apex, with the formation of adhesions at that point.

In the discussion on alienism, the subject of the causation of insanity was taken up by DR. JUDSON B. ANDREWS, of Erie County, in a paper on "Heredity and Environment." He expressed the view that the drift of thought tended to make heredity a *direct* and *exciting*, rather than a predisposing cause. To do this is to make life the result of an irresistible fate. It has been calculated that in the United States, in a population of one hundred thousand, there are two hundred insane people, of whom fifty would have an insane ancestry. There is a great tendency to exaggerate the force of heredity. Heredity alone does not produce insanity; its influence is to be found in a greater liability in the individual to become insane under some exciting cause existing in the environment. Dr. Andrews strenuously opposed the view that because insanity has existed in the family of a patient, there is little or no hope for the recovery of that patient. Those of insane ancestry may be confidently assured that there is no fatality about heredity, as it can only become a factor in the

production of insanity under conditions favoring the development of insanity, and these conditions are such as result in deterioration of the general health, and particularly of the vigor and integrity of the nervous system. These influences depend upon environment and not upon heredity. Environment, therefore, may be potent to intensify or to antagonize heredity. While heredity is most powerful at the adolescent period of life, there is also at this time the greatest mobility and the readiest control, as the environment is largely a matter of choice. In mature life there is much more danger of the development of insanity, but then there is an opportunity for the individual to so live as to overcome the hereditary influence.

Dr. H. M. Hurd, of Maryland, considered the relations of traumatism and shock to insanity. The far-reaching character of heat-stroke as a cause of insanity could not, in his opinion, be over-estimated. Cases of insanity following heat-stroke display the same suspiciousness and apprehension as those in which the insanity is due to traumatism. Shock sometimes produces an instability, rendering the patient emotional and lacking in will-power. Such cases yield the richest harvest to the hypnotist and mind-curer. Injuries to the head during childhood often lessen the brain-resistance and render the subjects liable to the development of mental disease at the physiological epochs of life, particularly at puberty. The most characteristic feature of traumatic insanity is constituted by delusions of suspicion and apprehension, and sometimes a tendency to vice and crime. With few exceptions the prognosis is bad.

Dr. P. M. Wise, of St. Lawrence County, discussed the relation of bodily diseases and senility to insanity. He quoted statistics to show that bodily diseases contribute from 12 to 14 per cent. of the cases of insanity in both sexes. Pregnancy and the puerperal state contribute 9 or 10 per cent. of the cases in females. Post-febrile insanities now form a smaller proportion than formerly, owing to the abandonment of depletive treatment. When the insane-diathesis exists, the patient requires extreme care during convalescence, to prevent the development of an incurable form of insanity. Heart-disease, on account of the attendant anemia, is often a direct physical cause of insanity, quite independently of other predisposing causes. The multiform traumatic causes furnish only a small etiological factor, and the same is true of sunstroke. For some years past, epidemic influenza has been assigned as a cause of melancholia; the great mental depression frequently accompanying influenza almost stamps it an epidemic nervous disease. It has probably been potent as a cause of insanity and of shattered nervous systems. The popular belief that diseases of the sexual organs bear a close relation to insanity is not well founded. Dr. Wise held that there is no uterine psychology; in a somewhat extensive experience with gynecologists in insane-hospitals, he had never seen a recovery from insanity even remotely due to gynecological treatment; he believed that in a few cases such treatment had actually interfered with recovery. The physiological epochs of life—pubescence, adolescence, and the climacteric—present fruitful periods for the unbalancing or unstable brains. Much might be said about the importance of harmony of development of the body and mind during the period of pubescence. The child-bearing processes act as frequent exciting causes in women, most often after the puerperium, and next in frequency during lactation. It is rare, however, for insanity to occur under these circumstances, without some preëxisting constitutional tendency, either inherited or acquired by a life of poverty and overwork. Protracted lactation in neurotic women is a perilous proceeding, and may result in life-long mental alienation. From a psychological standpoint there is a normal pathology of old age. Dr. Wise deprecated the growing tendency to certify as insane cases presenting this so-called normal pathology.

Dr. G. Alder Blumer, of Oneida County, took up the relation of syphilis and intemperance to insanity. He quoted statistics from various countries to show that, with the exception of France, the percentage of cases of general paresis in which syphilis exists as an antecedent condition is from 60 to 80. In regard to the proportion of forms of insanity other than general paresis due to syphilis, the statistics of the Utica Asylum show that the proportion of syphilitics to the total number admitted is 52 per cent.

Those having much experience with the insane will not deny that one of the most common causes of insanity is alcoholic excess. It seems probable that confirmed drunkenness of the parent is as potent as actual mental disease or mental deficiency to predispose to the development of insanity in the children; in fact, drunkenness is a transient insanity. Intemperance is often assigned as a cause, when in reality it is only a premonitory symptom. When directly the result of alcoholic intemperance, insanity is generally associated with systematized delusions and hallucinations of a persecutory character; this is not apt to be the case when insanity is a symptom of intemperance. Alcohol first excites, then paralyzes in succession every nervous center in the body.

Dr. E. N. Brush, of Maryland, confined his remarks to a consideration of arrest of development and diseases of infancy as factors in the causation of insanity.

Dr. W. D. Granger, of Westchester County, discussed "Causes of Insanity Peculiar to Women."

Dr. Charles Stedman Bull, of New York County, read an exhaustive paper on "Tumors of the Orbit and Neighboring Cavities.

Third Day—October 30th.

Dr. Henry D. Didama, of Onondaga County, read a paper entitled "Mental Therapeutics," in which he considered many of the cures that have been popular at various times, and deduced from them certain useful lessons.

Dr. Marcy, of Boston, and Dr. Fell, of Erie County, entered an earnest plea for better popular instruction on medical topics, a duty devolving upon each individual member of the medical profession. Dr. Fell spoke particularly of the frauds constantly being practised upon the community by irregular and unscrupulous physicians.

Dr. A. Palmer Dudley, of New York County, delivered the "Address in Gynecology." After reviewing the advances recently made in this department, he discussed the treatment of fecal fistula following laparotomy. Prophylaxis was of the greatest importance, most cases being preventable by careful and deliberate methods of

operating. Absolute rest in bed was requisite for the successful treatment of such a fistula, together with a diet that produced a minimum quantity of gas. Closure from the bottom could be promoted by passing daily through the fistula a piece of marine lint, soaked with balsam of Peru. Should the usual methods fail, a secondary laparotomy must be resorted to.

DR. GEORGE E. FELL, of Erie County, related a case of puerperal eclampsia associated with the uric-acid diathesis, and raised the question, What had this diathesis to do with the eclampsia? He cited some experiments demonstrating that in animals an excess of uric acid in the blood might give rise to convulsions. He also cited the case of a woman, who in the early months of pregnancy failed rapidly in health, coincidentally with the appearance of symptoms of the uric-acid diathesis, but who was rapidly restored to health by alkaline treatment, associated with daily irrigation of the bladder.

DR. FELL also reported "A Case of Embolism of the Pulmonary Artery Successfully Treated by the Persistent Use of Oxygen Inhalations." At the time the patient was first seen by Dr. Fell she was in a critical state and thought to be dying. The dyspnea, which was most distressing, was instantly relieved by the first inhalation of oxygen, and every attempt to discontinue these inhalations was followed by a return of the dyspnea and cyanosis. It was found necessary to use the oxygen continuously for four days, the total quantity used being nearly 1200 gallons. The object of the treatment was to keep up respiration and oxygenation for a time, in the hope that the embolism would be absorbed, and the obstruction thus removed. This occurred, and the patient eventually recovered.

DR. WILLIAM D. GARLOCK, of Herkimer County, read a paper on "Typhoid Fever in Children," in which he said that the most prominent symptom is the febrile movement, which begins earlier and rises more rapidly to the acme in children than in adults. The evening temperature is usually from 103° to 104.5°, and the ascending curve is not so regular as in a typical case in the adult. The whole duration of the fever is also shorter: of 80 cases, 7 lasted less than ten days; 30 from ten to fifteen days, and only 12 cases lasted the usual twenty-eight days. In children, the proliferation in Peyer's patches is more superficial than in the adult, and the proliferated cells undergo fatty degeneration and are absorbed without the formation of ulcers. In adults, the fever is partly due to the germs and the typhoid toxine and partly—*i. e.*, after about fifteen days—to the absorption of septic matter at the surface of the intestinal ulcers. As it is rare for children with typhoid fever to have ulcers of the intestine, they usually escape the period of secondary fever—hence, the shorter duration. The abdominal symptoms are usually not very well marked in children, but owing to the fact that the intestines of children are very easily irritated, the diarrhea is often more troublesome than one would suspect from the abdominal tenderness and tympanites.

DR. JOSEPH D. BRYANT, of New York County, considered the "Operative Treatment of Carcinoma of the Breast."

The requirements for successful operative treatment are (1) a prompt recognition of the growth by the patient herself; this can only be accomplished by individual effort on the part of medical men to impress upon the laity the importance of immediately attending to all growths about the breast, no matter how apparently insignificant, and by explaining the prospects of success, if this condition be complied with; (2) a prompt consultation with a careful and competent physician; (3) immediate, wide, and thorough excision of the growth and of all the tissues having functional connection with the gland. The incision should not be less than two inches from the apparent borders of the growth, and the operator should not concern himself about the amount of tissue removed, for if there be not enough left to form flaps and completely close the wound the granulating area can be quickly made to heal by skin-grafting.

DR. E. D. FERGUSON, of Rensselaer County, read an interesting paper on "Congenital Imperforate Rectum," and described the methods of treatment best adapted to the varying conditions.

AMERICAN PUBLIC HEALTH ASSOCIATION.

Nineteenth Annual Meeting, held at Kansas City, Missouri, October 20, 21, 22, and 23, 1891.

FIRST DAY—OCTOBER 20TH.

DR. C. D. MCDONALD, of Kansas City, read a paper on "The Cause and Prevention of Infant Mortality," giving statistics showing that the mortality of infants soon after birth was 20 per cent., of which one of the principal causes was exposure to a low temperature. Inducing sleep by means of soothing syrups is another evil. Still another is the forcing of improper food, such as crackers, and water and whiskey into the stomach of the newly born.

Statistics show that in the first year of life the mortality among infants fed upon artificial food is 50 per cent.; with the employment of natural food, the mortality is but 10 per cent. The best artificial food is pure cow's milk. Sterilization by chemical processes is not thoroughly successful, because vital principles cannot be supplied by chemical processes, but sterilization is preferable to impure milk.

Starchy substances cannot be digested by the infant's stomach. By the chemical processes of the stomach, they are first converted into sugar, then alcohol, and then acetic acid. Improper dressing—thin clothes—is also a prolific source of disease among infants.

PROF. W. W. DANIELLS, of Madison, Wisconsin, expressed the view that no one should be allowed to sell milk in cities unless he put his dairy establishment under the control of the sanitary authorities.

DR. JOSEPH SHARP, of Kansas City, Missouri, read a paper on "Glanders in Man," in which he presented the report of a case. He recommended that to prevent glanders, those who came in contact with horses having open sores or discharges from the nose should disinfect the hands with a solution containing a tablespoonful of equal parts of glycerin and carbolic acid in a quart of hot water, or ten grains of corrosive sublimate in a quart of water.

DR. PAUL PAQUIN, of Battle Creek, Michigan, reported a collection of seventeen cases of glanders in man. He related the case of a man who, driving behind an affected

horse, was struck in the eye by a spray from the beast's nostrils, as a result of which glanders rapidly developed and terminated fatally.

CHIEF JUSTICE HORTON, of Kansas, read a paper on "The Necessity for More Stringent Legislation to Repress Empiricism," in which he recommended that, for the protection of the public, the American Public Health Association should recommend the enactment of statutes excluding from the medical profession those who are not competent by learning, skill, and experience to practise, and punishing by imprisonment any who violate the provisions. No one should be permitted to practise medicine or engage in surgery unless authorized to do so by a competent board of Government or State examiners.

MR. ALLEN HAZEN, of Lawrence, Mass., read a paper on "Water-supply and Public Health," in which he maintained that as the germs of typhoid fever and of cholera gain entrance into the system with food and drink, pure water is a necessity. If water is absolutely free from sewage, it can be depended on as being comparatively pure, although many waters not polluted by sewage have been known to breed disease. Flowing streams will partially purify themselves. Water will not always become purified in reservoirs and long channels. Some system of filtration is therefore imperative, and the question to be decided is as to the best system of filtration.

DR. HENRY B. HORLBECK, of Charleston, S. C., presented some vital statistics from the Southern States, showing the death-rate among the colored population to be much greater than among the whites.

DR. FREDERICK MONTIZAMBERT, of Quebec, delivered the President's Address. He stated that the objects of the meeting were to quicken interest in the more purely preventive work of the profession, to increase interest in the organization and working of the coast quarantines and health-boards, in the sewage of cities, the disposal of garbage and refuse, the purity of water-supply, the infectious diseases of animals now known to be closely related to those of man, as well as other much broader questions of modern sanitation.

SECOND DAY—October 21ST.

DR. PAUL PAQUIN, of Battle Creek, Michigan, read a paper on "Vaccine and Vaccination," in which he dwelt upon the necessity for employing absolutely pure vaccine.

DR. YESI, of Mexico, spoke of the compulsory vaccination of Mexico. Only human vaccine is used. Vaccine from the lower animals is not cultivated. Better results are obtained from human than from animal vaccine. A serious smallpox epidemic has not visited that country in about twenty-five years.

DR. L. F. SOLOMON, of New Orleans, La., stated that in Louisiana each child must show a vaccination certificate before being allowed to attend school. About 90 per cent. of the primary vaccinations were successful. He favored the use of bovine virus.

DR. DELOS FALL, of Albion, Michigan, read a paper on "The Disposal of Garbage and Refuse," in which he discussed the intimate relation between typhoid fever and the accumulation of waste organic matter.

DR. EDWARD CLARK, of Buffalo, New York, made a report on the collection and transportation of garbage and refuse in cities. He advised full police power for the sanitary service of large cities. A galvanized iron tank holding about two or three bushels is the best receptacle for holding household garbage. The refuse tank must not be placed on the street or sidewalk, but the collector should be compelled to go to it, remove the contents, and replace the cover. For transporting garbage, carts are preferable for short, and wagons for long, hauls. The beds should be made water-tight and should be flushed after each dumping. The bed should be covered with iron.

DR. J. J. KINYOUN, of the U. S. Marine-Hospital Corps, read a paper on "Rabies," in which he said that the disease is transmitted almost wholly by the canine and feline species. It prevails all over the world, except in Australia, where it is not known. He opposed the idea that the disease occurs only in warm weather; statistics show that the greater number of cases occur in December and May. Recognition of the disease is not easy in any animal in the early stages. Dr. Kinyoun advocated the establishment and enforcement of strict quarantine regulations in order to eradicate the disease.

DR. P. C. REMONDINO, of San Diego, Cal., read a paper on "American Climates and their Physical Effects," in which he said that European immigrants soon lose their ruddy cheeks and bright eyes, with a certain loss of spirit, when they come to this country, because they lived in disregard of all hygiene or science. In changing climate they followed no rational rules for the necessary change of diet.

In a paper on "Animal Diseases" MR. ERNEST L. DUNDAS, of Kansas City, recommended police supervision of all milk dairies. He stated that the Jersey cow is the most generally afflicted with tuberculosis.

DR. PETER BRYCE, of Toronto, stated that in Canada milch cows were never bred, and in one city they are never used after they have once been dry, but are immediately sent to the butcher. It seemed to him that in view of the fact that there are 15,000,000 cows daily supplying the country with milk, and that in certain abattoirs from 5 to 10 per cent. of the cattle killed are tuberculous, there should be a most rigid and regular inspection of all milch cows.

DR. DOMINGO ORVANANOS, of the City of Mexico, presented a paper entitled "New Organization of the Supreme Board of Health of Mexico," in which he outlined the work of the Mexican Supreme Board of Health, of which one exceedingly good feature is the sending of a surgeon-physician with every ship leaving Mexican ports, who shall be held responsible for the sanitary condition of the vessel, and who shall be obliged to report to the Mexican consul at every port where the vessel may touch, and obtain from him a clean bill of health.

DR. GEORGE HOMAN, of St. Louis, Mo., read a paper on "Land Habitation as a Public Health Measure," in which he endeavored to demonstrate the benefits that would arise by the individual ownership of homes, as that would render less likely the dissemination of any communicable disease, and would render easier the measures to be taken against disease by permitting isolation, a most desirable feature in combating contagious disease.

Third Day—October 22d.

Dr. Peter H. Bryce, of Toronto, read a paper entitled "The Present Position of the Milk-supply Problem from the Public Health Standpoint, and Some Practical Methods for Securing Safe Public Supplies," in which he briefly summed up the precautions necessary to secure healthy milk:

1. It is especially desirable that a system of periodic veterinary inspection be exercised, in addition to the dairyman's inspection.

2. Careful supervision should be exercised as to the nature and quality of food for cows. All decomposed foods, such as those that are liable to undergo fermentation, should be wholly avoided. The best foods are well-ripened grains and grasses.

3. The stables for cows are too often dark, damp, ill-ventilated and crowded pens. It is quite possible to keep a dairy stable, even on a large scale, free from the ordinary disagreeable stable odors. The water-supply of the cows is of equal importance.

4. The care of the milk at the time of taking and subsequently is of all points the most difficult and the most necessary to a supply of wholesome milk. This means almost a revolution amongst farmers and dairymen. The sterilizing of all cans and bottles by steam or dry heat and the boiling of all strainers will be necessary.

5. The delivery of milk is of prime importance.

6. When milk has reached the consumer it must be placed in a refrigerator or be promptly consumed.

Fourth Day—October 23d.

Prof. W. W. Daniells, Chairman, of Madison, Wis., read the Report of the Committee on Car Sanitation, in which it was shown that the great difficulty in the heating arrangement of cars was that all systems devised for the purpose provide for heat alone, and not for ventilation.

At the conclusion of the meeting a resolution was passed that in 1893 the Association should hold its meeting in Chicago, and that, so far as possible, the occasion be made an international congress of hygiene and public health.

The following officers were elected for the ensuing year: *President*, Dr. Felix Formento, of New Orleans, La. *Vice-Presidents*, Dr. Walter Wyman, of Washington, D. C., and Dr. Domingo Orvananos, of Mexico. *Secretary*, Dr. Irving A. Watson, of Concord, N. H.

The next meeting is to be held at the City of Mexico, at a time to be fixed by the officers of the Association.

CORRESPONDENCE.

NEW YORK.

The Filthy Streets—The Disposition of Stable-Refuse—Operating Theater of the Roosevelt Hospital—Case of Extreme Deformity—New Method of Staining Bacilli—Hydrophobia or Lyssophobia.

In my last letter I had occasion to speak of the filthy condition of our streets, and its effect upon the public health. It was not a new story to those who had resided in our misgoverned city, but it seemed at that time as if even our long-suffering citizens had nearly reached the limit of their patience. Since that letter was written, the Mayor, in tardy response to the public outcry, has removed the utterly incompetent street-cleaning commissioner, and has appointed a much more energetic and business-like man in his place. How much the Mayor was influenced by the action of the Academy of Medicine, I cannot say, but it is encouraging to note that this body of medical men felt called upon to direct special attention to the unsanitary condition of the city, and to emphasize the importance of the labors of the advisory committee which the Mayor appointed to inquire into this subject. In the discussion in the Academy on the adoption of these resolutions, Dr. Abraham Jacobi very pointedly remarked: "It seemed that instead of teaching the poor immigrants how to be clean, we learned from them how to be dirty, and it was particularly unfortunate that most of the dirt accumulated in those districts which are the most densely populated."

Another matter closely touching upon the subject of the public health, as well as upon the public comfort, concerns the disposition of stable-refuse, and although this may seem to be a rather odd subject to interest ladies, it has not escaped the vigilant eyes of the members of "The Ladies' Health Protective Association." This band of workers has taken up the cudgel in earnest against the stable-keepers who still persist in disposing of their stable-manure after the methods of their forefathers. This has long been a bone of contention with the sanitary authorities, and as long ago as 1866, when the Board of Health was organized, this was among the first and most difficult problems which confronted the Board. At that time, the greatest nuisance of this kind was at Forty-sixth Street and the East River, where large quantities of manure were dumped and allowed to remain all through the winter months, the heaps being frequently stirred up to prevent the manure from spoiling. While the health authorities have done much since then to abate such nuisances, there is still much to be done, and hence, the ladies of this Association, making common cause with the Section on Public Health of the Academy, set apart one evening for a joint discussion of the subject. Dr. F. R. Sturgis said that he had observed that very severe cases of diphtheria were particularly frequent in families living over stables. The large stables could easily and profitably make use of the baling machine, but in the establishments having only from two to ten horses there would be much difficulty in enforcing a rule requiring all manure to be baled, for the manure would have to accumulate for some time before it could be baled. If the health authorities would allow the small stables to put up the manure in barrels, then one of the greatest difficulties connected with this subject would at once disappear. But before the stablemen can be won over to our way of thinking, they very naturally insist upon knowing whether baling will lessen the commercial value of the manure. Experiments carried on by the chemist of the Board of Health have shown that the manure is not wet enough to lose any of its valuable properties by the process of baling, and that manure which has been kept in bale for thirty days has not deteriorated in the least. Major Bullard, the chief inspector of the Board of Health reported that under a

systematic weekly inspection, accumulations of stable-refuse upon the docks had been effectually prevented. There are upwards of sixty thousand horses in the city, and as 1100 loads of manure are removed daily, it does not seem probable that much is left in the city. These figures are founded on data gathered by the Board of Health. There is very little baling now going on, but about twenty-five per cent. of the stables are disposing of the manure in barrels. Dr. Alexander Hadden approved of the suggestions that had been made, but he thought we were not doing ourselves much credit by dumping the manure upon our neighbors, and on this account more stringent measures should be adopted, with the idea of preventing the unbaling of the manure until it reaches the consumer. It was resolved at this meeting to urge upon the Board of Health the enactment of a law making it unlawful after the first of October to transport manure in the built-up portion of the city, except in bales, or in properly covered receptacles. I have not been able to learn whether such a regulation is yet in force.

The handsome new operating theater of the Roosevelt Hospital is rapidly nearing completion. It is intended that it shall embody all the latest improvements of construction, as well as be supplied with the most approved of the many appliances used in modern surgery. To this end, Dr. Charles McBurney, who has entire charge of the arrangements of the building, spent some time in Europe last spring, gathering together the most recent ideas, in order that this magnificent contribution to surgical science may be made the most perfect of its kind in the world. I hope before long to be able to furnish a more detailed description of it.

A few days ago, Dr. Reginald H. Sayre exhibited before the orthopedic surgeons a case of extreme deformity from congenital lateral curvature of the spine. The patient, who is now fourteen years of age, presents a large V-shaped gap in the ribs on the right side of the thorax, through which the liver can be readily felt. The chest is of course very greatly distorted. the respiratory sounds are puerile, but the heart-sounds are normal. When she was first seen by Dr. Sayre, about one week before, her height was four feet six and three-quarters inches, but after being suspended in the spinal swing, there was a gain in height of five-eighths of an inch, and strange to say, this gain has been permanent. Dr. Sayre stated that he had met with several cases in which there was a permanent increase of stature as the result of this treatment.

A new method of rapidly staining bacilli in sections of tissues, which appears to possess some practical advantages, has been recently brought forward by Dr. J. M. Byron, of the Loomis Laboratory. The peculiar feature of the process is the way in which the sections are made to adhere firmly to the cover-glass. This is effected by immersing them in an albuminous fluid, and then coagulating the albumin. The sections, after being well rinsed with water, are put into a solution of equal parts of egg-albumin and a concentrated solution of boracic acid, the latter being added to preserve the albumin. When thoroughly soaked, they are transferred to a cover-glass, dried, and then immersed in a solution which will coagulate the albumin—*e. g.* absolute alcohol, equal parts of alcohol and ether, or better, a one per cent. solution of bichloride of mercury in absolute alcohol. After washing with water, they are stained by any of the ordinary methods.

The case of hydrophobia recently reported in the daily papers as occurring about a fortnight ago in Elizabeth, New Jersey, is one that may prove of more than usual interest to those here who are making a special study of this disease. A boy, eight years old, in the latter part of July was bitten by a dog, and was treated in the Elizabeth Hospital. The wound healed naturally, and the boy was kept in the hospital for some time, and seemed to be perfectly well. He was discharged from the hospital October 1st, and about a week later developed symptoms that the attending physicians thought were those of hydrophobia. I am told that the patient presented exaggerated reflexes, and when disturbed, suffered from spasms. His temperature ranged quite high—104° or more—and the symptoms, according to one observer, were more like those of a severe case of typhoid fever than of hydrophobia. My reason for saying that this case may prove more than usually instructive and interesting is that some observers incline strongly to the belief that most, if not all, the cases of so-called hydrophobia in the human being are really instances of lyssophobia, or a "dread of hydrophobia." Among those who advocate this doctrine is Dr. J. M. Byron, who, in a discussion upon hydrophobia at the last meeting of the Neurological Society, brought forward some of the grounds for his belief.

The five cases that he reported would have undoubtedly gone on record as instances of hydrophobia had they not been subjected to a searching investigation according to the methods pursued in our modern laboratories. The modern scientist it not content with calling a case hydrophobia simply because the hapless patient was at some time, more or less remote, bitten by a dog, nor is he satisfied with a plausible array of symptoms. He must have some of the patient's spinal marrow, and must inoculate a series of rabbits with this, and wait for a number of weeks to see if these animals develop rabies. Even this will not always suffice for our modern skeptic, who will not admit the case to be certainly one of rabies until this disease is produced in other rabbits inoculated with virus taken from the first series. It is after this fashion that Dr. Byron has weighed his cases in the balance, and has found them wanting. In one case, the post-mortem examination showed death to have been due to a hemorrhage at the base of the brain; in another, the negative results of laboratory experiments, together with the symptomatology, pointed to acute mania as the probable condition; in a third, death was due to an ascending paralysis, and the two remaining cases were examples of pure lyssophobia. The case in which death is ascribed to ascending paralysis is especially interesting, as it occurred in the person of a physician who assisted at an autopsy made upon one of the other cases. He received a slight wound at the autopsy, and shortly afterward developed symptoms that suggested to some the possibility of his having hydrophobia. He accordingly received the regular Pasteur treatment, but the course of the disease was in no way stayed, but rather seemed to become worse. The physician who performed the autopsy also wounded himself quite severely with a knife at the time he was en-

gaged in cutting that part of the body in which the virus of rabies is conceded to be the most virulent, viz., the spinal cord, yet he suffered no inconvenience from the wound, and has remained in perfect health. Some of those who saw the fatal case were of the opinion that death actually resulted from the antirabic inoculations, but the subsequent examinations did not confirm this view. If, as Dr. Byron seems to believe, nearly every reported case of hydrophobia is really one of lyssophobia, which may be roughly compared to a grave case of hysteria, it is pertinent to inquire how the boy in Elizabeth, who was too young to have any "dread of hydrophobia," and who had no idea that he was even dangerously ill, could be a victim of lyssophobia.

OBSTETRICS IN MEXICO.

To the Editor of THE MEDICAL NEWS,

SIR: The practice of this particular branch of medicine in this part of Mexico is not surrounded by all the conveniences that one of the progressive modern school might desire, which is a mild way of saying that the path of the practitioner is beset by all the difficulties and strewn with all the horrors that ignorance, superstition, squalor, and filth are continually opposing to the efforts of science. The Mexican law requires that the "parteras," or midwives, shall have a diploma showing that they have undergone a certain amount of instruction. The intention of the legislator was good, but it is as inefficient as other good intentions, which are said to make good paving material in a place which is hotter even than this place in the "rainy season." In this town of five thousand inhabitants, although there are a number of women who follow this avocation, there is not one who has fulfilled the requirements of the law. As might be expected, there is a great deal of bad obstetrics practised. The physician is called only to those cases that are complicated or become so through mismanagement. I give reports of a few cases to which I have been called.

November 1, 1891, at 5 A.M., I was summoned to see a young primipara, and found the following condition of affairs: The parturient female was squatting on the floor or ground in a small hut, and the midwife kneeling in front of her was engaged in making active compressive movements upon her abdomen. I made the woman assume the recumbent posture, and then loosened a cinch which was tied very tightly about her middle and which was almost cutting her in half. I always find this sinch tied very tightly about a woman, no matter what may be her trouble, perhaps from some superstitious belief in the merits of tight lacing, which is not confined to these parts. Upon inquiry, it became evident that the woman had been in labor about twenty hours; that at 1 A.M. a child had been born, and at that time the midwife discovered that the uterus contained another child. During the four hours that elapsed between the birth of the first child and my appearance upon the scene the midwife had been engaged in ineffectual efforts to expel the child by squeezing the abdomen. By palpation, I discovered the fundus of the uterus lying to the right side and the child in the transverse position. Vaginal examination revealed the fact that a hand and an arm were protruding. Although uterine contractions were fairly strong, of course the child could not be born.

I determined to do podalic version and terminate the labor as soon as possible. No assistance was obtainable whatever, except a few ignorant Mexican women and the father of the patient, and these objected to the procedure. Having silenced them by asking Why, then, have you sent for me? I administered chloroform and then introduced my right hand into the uterus, steadying that organ with my left. Passing the right hand to the fundus I was successful in grasping a foot and, bringing it down, quickly delivered a child which had the appearance of having been dead for some time. The placenta was delivered by the method of Credé, and a uterine douche of bichloride solution of 1:1500 was given. There were no bad results, no appreciable rise of temperature, and the woman wished to get up on the second day.

The second case occurred several days later and was that of a multipara, who was suffering from retained placenta. In a previous labor she also had the same trouble. My predecessor had performed the operation for extraction of the placenta without the use of an anesthetic. I gave chloroform and extracted the placenta with some difficulty, as it was firmly adherent. The after-treatment was the same as in the preceding case, and was followed with equally good results.

The third and last case which I cite was that of a primipara who had been in labor two days. Upon my arrival I found the woman squatting, holding with both hands to a rope attached to a beam in the roof, the midwife in front of her pressing upon the abdomen and with her other hand in the vagina trying to pull down the child. I made the woman lie upon the floor (there was no bed or table in the hut nor in procuring distance), and upon examination discovered that the head was in the L. O. A. position, but had not entered the pelvis on account of discrepancy in size. I administered chloroform and proceeded to do the high forceps operation. The operation was attended with considerable difficulty, as I was oblighed to sit upon the floor and work in that disadvantageous position. After pulling for thirty minutes I succeeded in extracting the head, there being in the meantime no uterine pains, as the uterus was exhausted. During the process of the operation the midwife, who was also the mother of the woman, became maudlin-drunk (she was moderately so when I commenced), and I was obliged to dispense with her services and relegate her to the outside. My assistants (?) were then limited to the husband of the parturient and two women, who held her while I pulled. I would pull them all four across the floor, and then we would take the patient back and commence over again. Finally, I discovered that progress was being made, and taking the forceps off, the child was delivered with the heart beating feebly, but it stopped, and all efforts to restore it to life were unavailing. The mother of the woman rallied sufficiently to keep the patient awake all night, giving as a reason her fear that if she went to sleep she would never wake up. There was a laceration of the perineal body and retention of the urine for about two days, but with these exceptions, the woman made a good recovery.

BATOPILAS, MEXICO.

SENDING INVALIDS AWAY FROM HOME.

To the Editor of THE MEDICAL NEWS,

SIR: After spending several winters wandering about the South in search of relief for certain bronchial troubles, I feel myself competent to make some remarks deserving consideration.

In the first place, I wish to record my indignant protest against the practice of sending incurables away from home. A large proportion of the invalids one meets in the South are the victims of cruelty or ignorance on the part of their medical advisers, who indiscriminately use a method of treatment that can be of advantage only in the first stages of disease. In most of the so-called "health resorts" there is no provision made for those that are seriously ill. The hotels and first-class boarding-houses do not want them, and the idea of a second-class boarding-house, crowded with these misguided creatures, is something awful to contemplate. I can bear witness, that in many instances death is hastened by the want of proper food and the home-sickness that comes from unpleasant surroundings; and the blame lies at the door of the doctors who pack their patients off, so far as they are concerned, literally to "parts unknown." Certainly, no conscientious physician, having a personal knowledge of these places, would send thither patients in the advanced stages of disease without first making sure that they will be placed under the most favorable circumstances. Without such provision, they will be almost sure to come back in their coffins, or die on the road in the struggle to get to homes they never should have left. If possible, a house should be taken for such persons, and they should be surrounded by their friends and the comforts to which they have been accustomed. For those that cannot afford this, any decent home in the vilest climate in the world is a better place than any "health resort" in the South with which I am acquainted.

Again, while there is no doubt in my mind that many persons in the incipient stages of phthisis, as well as those that are only delicate, are greatly benefited by escaping from the harsh northern winter, I am sure that much harm is done by making the change too great. The idea of a "vestibule train" that takes you from New York in a snow-storm, and lands you among the orange groves of Florida within twenty-four hours, is fascinating in the extreme; but the results are not good. In a normal season the transition is too sudden, and one finds the heat oppressive and debilitating. Great circumspection is required in making a change of clothing, because a drop from 80° to 40° is far more trying than one from 40° to zero, and such changes as the first and even still greater, are not uncommon, even among the orange groves.

For the benefit of the busy practitioner who has no time to look for himself, I venture to suggest that even his consumptive patients, properly selected, will show better results in the bracing air of such a place as Marietta in the highlands of northern Georgia; or at Aiken, still worthy of its old-time reputation; or, better still, among the sand hill pines of historic Camden, with its picturesque old mansions, and a well-sustained reputation for good living handed down from the luxurious old planters of the ante-bellum days of South Carolina.

Finally, bitter experience has taught me that no delicate person who has passed the winter in the South should trust himself in the treacherous climate of the regions about New York or Boston before July 1st.

SAG HARBOR, L. I.

UNUSUAL MODE OF TRANSMISSION IN A CASE OF DERMATITIS VENENATA.

To the Editor of THE MEDICAL NEWS,

SIR: In your issue of October 24th I see the report of a case of unusual mode of transmission in a case of dermatitis venenata. I wish to report a parallel case. One of the severest cases of dermatitis I have seen occurred in a lady, Mrs. E., aged fifty-three. On July 21st, the patient, a near relative, asked me to give her something for "hives." She was given what was deemed necessary, and on the 24th, as she walked with difficulty and seemed to be suffering considerably, I ordered her to bed, and on inspecting the parts found buttocks and thighs edematous, very red and hot, and covered with small vesicles, which were not easily ruptured. She complained of intense burning and itching. Having had wheals that itched in conjunction with mosquito-bites, and having scratched herself quite severely, I looked on the case as one of eczema, the result of the scratching—an artificial eczema. Zinc and calamine lotion, carbolic acid spray and other applications seemed not to relieve her. She remarked that her trouble reminded her very forcibly of ivy-poisoning, which she had once had. As she had not been exposed, so far as we could ascertain, the idea was not long entertained. She suffered excessively, and the next day I asked Dr. J. B. Keber, Professor of Dermatology at the Beaumont Hospital Medical College, to see her with me. He pronounced it a case of dermatitis venenata. Where contracted?

The patient remembered that her husband had been to the country on two occasions just a few days before she became affected, and that he had had a slight skin eruption, reddish in color, with a few "small blisters" that itched, on his forehead, cheek, and wrists. It was so slight as to be hardly noticeable. She herself had applied a soothing lotion to the affected regions, using her hands to mop it on, at the same time or shortly after scratching a mosquito bite on her right knee. The next day she noticed the wheals, which led her to make a diagnosis of hives; and things rapidly went from bad to worse. The husband was examined, and desquamation was in progress on his wrists and forehead. Here, then, the husband carries the poison, having a very slight eruption, and the wife infects herself and suffers in a very distressing manner.

Grindelia robusta gave her no relief; powdered aristol, a mention of which was seen in THE MEDICAL NEWS, was given a trial, and proved of no value. Sulphate of zinc, as a lotion, and carbolic acid with oil of peppermint, in the shape of a spray, gave the most relief. Fully two weeks elapsed before the patient was able to be about again with any degree of comfort.

W. L. BLICKHAHN, M.D.

ST. LOUIS, MO., Nov. 4, 1891.

WASHINGTON AS A MEETING-PLACE.

To the Editor of THE MEDICAL NEWS,

SIR: I consider Washington to be so clearly the best place for our Congress that I am moved to say a word as to the cause of the diarrhea from which I, in common with many others, suffered during our second and very successful meeting.

The water was not to blame. I drank no drop of it, except as it was used boiled in coffee. I know of others who suffered despite this and every other precaution; also, the manifestation was too general to have been due to food, for it affected people living in hotels and in private houses. Finally, it existed over a large part of the country—in Newport, R. I., for instance, whither I went after a week in the Maryland hills, where also it was sharply felt. The cause, therefore, was not the product of Washington, nor should it be allowed to influence us when again we come to summon, for a like purpose, the remarkable body of men which constituted the Congress.

Yours truly,

WEIR MITCHELL, M.D.

1524 WALNUT STREET, PHILADELPHIA.

CORRECTION.

To the Editor of THE MEDICAL NEWS,

SIR: Will you do me the favor of making the following corrections in the report of my remarks before the American Electro-therapeutic Association that appeared in THE MEDICAL NEWS of October 31st. Near the bottom of the second column of page 521 I am represented as saying that I had abandoned puncture because I feared failure. What I did say was that I had abandoned abdominal puncture, not because I had any bad results, but because I feared unpleasant consequences, as others had reported them. I am still in favor of vaginal puncture, and believe it harmless when properly done under appropriate indications.

The final sentence of the second paragraph on page 522 should read: "In some sensitive conditions the negative pole cannot be used satisfactorily unless the faradic current is employed afterward."

A. H. GOELET, M.D.

REVIEWS.

THE REFRACTION OF THE EYE: A MANUAL FOR STUDENTS. By GUSTAVUS HARTRIDGE, F.R.C.S., etc., with ninety-eight illustrations and test types. Fifth edition. Philadelphia: P. Blakiston, Son & Co., 1891.

THIS most excellent handbook is now so well known as perhaps the best concise, small treatise upon the subject that nothing more is needed than merely to call attention to the introduction of considerable new matter into the fifth edition and a careful revision of the whole work. The only fault that may be found with the work is one that it has in common with all works of the kind: after the refraction is made and the prescription written no word is said as to the hundred and more faults of construction and adjustment of the spectacles that neutralize, change, or increase the improper functions of the eye which the oculist hoped to correct. Hardly one out of a hundred pairs of spectacles sold and worn is properly made or accurately and scientifically adjusted. Every such fault has a medical significance. This dereliction of duty on the part of the optician is at the expense of the oculists, and these should hammer away at the wrong until it is corrected. There is no reason against, but many for, the advisability of the physician taking the matter up himself.

A CLINICAL TEXT-BOOK OF MEDICAL DIAGNOSIS FOR PHYSICIANS AND STUDENTS, BASED ON THE MOST RECENT METHODS OF EXAMINATION. By OSWALD VIERORDT, M.D., Professor of Medicine at the University of Heidelberg. Authorized translation from the second improved and enlarged German edition, with additions. By FRANCIS H. STUART, M.D. With 178 illustrations, many of which are in colors. 8vo., pp. 700. Philadelphia: W. B. Saunders, 1891.

WE regret that this good translation of an excellent book is marred by a large number of errata, some of which are noted in a table, and others, such as *sulphate* of ammonium for ammonium *sulphide*, *chloride* of mercury for *bi-chloride* of mercury, and the like, must be detected by the reader. The directions for examinations of patients are thorough, detailed, and accurate; and the explanation of the signs and symptoms discovered, while not in all cases beyond dispute, is at least tenable, and in the main that which has received the support of the best professional opinion. The arrangement of the material is admirable. General considerations precede detailed study of special organs. In the special sections the order is logical, and the phraseology, when not obscured by the translator, lucid. Space does not permit us to review in detail the views of the author or to criticise other than a few special points.

We would suggest that in the section upon subnormal temperature, mention might have been made of the continuous subnormal temperature which occurs at times in epidemic influenza, and even persists long after recovery from the acute symptoms; while the statement that subnormal temperature during recovery from fever occurs only at crises is misleading, for, as all know, it is an ordinary feature of convalescence from typhoid. We are glad to note the importance paid to inspection of the thorax—a method of examination too often neglected, probably because of the trouble and loss of time involved in removal of the clothing. We should hesitate to diagnosticate any case of thoracic disease without inspection of the naked chest. The author believes that "lagging" of one side or one portion of the chest, detected most easily by palpation, may be for some time the only symptom of beginning phthisis, of pneumonia, pleurisy, infarction, etc. The acoustic principles underlying percussion and auscultation are well elucidated. We note in passing that the author lays comparatively little stress upon the so-called "cracked pot" sign as indicative of a cavity. Much more significant does he consider change of sound upon opening or closing the mouth while percussion is made over a cavity (Wintrich), and the change in percussion-sound produced by difference of posture and due to the shifting of fluid within the cavity (Gerhart). In the excellent study of cardiac sounds, we should have liked to have seen some emphasis laid upon the frequent occurrence of an aortic

systolic murmur that is not due to stenosis. The section upon sphygmographic signs is much better than in most books of the kind; that upon microscopic examination of the blood is also very good. Among throat affections we are glad to find "pharyngo-mycosis leptothricia" specifically recognized. The section upon the examination of the contents of the stomach, as might be expected in a German treatise, is quite full. That upon cerebral localization is illustrated with a number of very good diagrams. There is a fairly good index.

While for distinct pictures of special diseases, such as we find in Da Costa's *Diagnosis*, one searches this volume in vain; on the other hand, it has a special value of its own in that it gives much detailed information concerning methods of examination, not to be found so readily and so consecutively in other works. We can cordially recommend it to the physician and to the student as one of the most useful of a number of works upon diagnosis which they will need in study and in practice.

Transactions of the Southern Surgical and Gynecological Association. Volume III. Third Session, held at Atlanta, Ga." 8vo., pp. xli, 444. Published by the Association. Philadelphia: Wm. J. Dornan, 1891.

This volume is made up of thirty-one essays upon surgical and gynecic subjects, together with the discussions thereon. The field covered is a wide one, which will prevent a detailed review. In general it is sufficient to say that the character of the papers and discussions is high, and reflects credit upon the Association. Among the papers deserving special notice, either because of the excellence of their preparation, or because their appearance is opportune, we mention: "The Health of the American Girl, as Imperilled by the Social Conditions of the Day," by George J. Engelmann, M.D.; "How shall we Treat our Cases of Pelvic Inflammation," by Richard B. Maury, M.D.; "Inflammation In and About the Head of the Colon," by L. S. McMurtry, M.D.; "Operation in Ectopic Pregnancy," by Charles A. L. Reed, M.D.; and "Cancer of the Cervix Uteri in the Negress," by Howard A. Kelly, M.D.

The article by Dr. Engelmann is a careful review of the modern conception of the relation between civilization, especially current educational and social methods, and sequal disorders in women. It is presented in the thoroughly complete and scientific manner characteristic of its author. The immediate future will demonstrate the truth or falsity of the author's views; for if true, the very general diffusion of the modern education among the people will produce results so palpable as to be demonstrative.

Dr. Maury presents the modern conception of pelvic inflammation: the pathology, that of Bernutz; the treatment, that of the gynecologists of the day. The pathology of non-puerperal pelvic inflammation is salpingitis, with its complications; that of puerperal pelvic inflammation is usually the same, but at times is a true cellulitis. Cellulitis is an acute, not a chronic condition. The treatment of salpingitis, except in mild cases, and especially when pus is present or attacks of peritonitis recur, is removal of the uterine appendages by abdominal section. The discussion showed that the sound views of the author were shared almost unanimously by the Association.

The paper by McMurtry on appendicitis, and the discussion, are in entire accord with the recent papers by Fitz, Weir, Treves, Morton and McBurney. The trend of opinion is decidedly toward early operation for appendicitis—on or before the third day, unless improvement takes place—and toward immediate operation for perforation or spreading peritonitis. The evil effect of opium in masking the real nature of the case is insisted upon.

Dr. Kelly reports two cases of epithelioma of the cervix in the negress; one of the women, so far as could be learned, was a pure negress, while the other had a slight admixture of white blood. Allusion is made to four other cases of carcinoma in the negress seen by him in Baltimore, and to a case recently published in Boston. These cases comprise the literature of the subject. Heretofore the negro has been thought to be exempt from carcinoma. In all the cases, there was perhaps an admixture of white blood some generations back; or it may be that the influence of civilization has made the tissues of the negro vulnerable to carcinoma.

Diseases and Refraction of the Eye. By M. C. Macnamara, F.R.C.S., Surgeon to the Royal Westminster Ophthalmic Hospital; Surgeon and Lecturer on Surgery, Westminster Hospital, etc.; and Gustavus Hartridge, F.R.C.S., Surgeon to the Royal Westminster Ophthalmic Hospital; Ophthalmic Surgeon to St. Bartholomew's Hospital, Chatham, etc. Fifth edition. Small 8vo, pp. xv., 604. Philadelphia: P. Blakiston, Son & Co., 1891.

The incorporation of the fifth edition of the well-known students' manual on the *Refraction of the Eye* of Mr. Hartridge with Mr. Macnamara's *Manual of the Diseases of the Eye* into a single volume is a most excellent and happy combination. Careful comparison of the two parts with the last editions of the authors' previously separate works shows extensive and painstaking revision. Amongst the most important changes, the entire subject-matter has been brought to date, side-headings, names of authorities, and the imperfect chromolithographs found in the work of Mr. Hartridge have been all properly omitted; the sequence and naming of chapters have undergone rearrangement; and even entire paragraphs have been transposed, judiciously pruned and rewritten: altogether, there has been much gained by the association. Unfortunately, however, the chapter on anatomy by Dr. Johnson, which prefaced the last separate volume of Mr. Macnamara, has been broken into parts, with and without foot-note references to the writer, and relegated to the various chapters to which the special subjects belong, thus causing the work of Dr. Johnson to practically lose its autonomy in the combined volume.

After a most pleasant and instructive reading of the entire volume, it can be justly said that both the authors and the publishers are to be congratulated upon the careful revision and excellent production of this most praiseworthy work—a work which, we unreservedly as-

sert, is, for the student and the general practitioner, without exception the best, the safest and the most comprehensive manual upon the subject published at the present time.

NEWS ITEMS.

The Orton Prize.—At the annual meeting of the New York State Medical Association, held in New York on October 28–30, the J. G. Orton Prize of $100 for the best short, popular essay on some subject connected with practical sanitation was awarded to Dr. Howard Van Rensselaer, of Albany, N. Y., for an essay on "Impure Air, and the Ventilation of Private Dwellings."

The Medical Society of the State of New York will hold its next meeting at Albany, February 2, 3, and 4, 1892. Dr. Seneca D. Powell, of New York; Dr. James D. Spencer, of Watertown; and Dr. Franklin Townsend, of Albany, have been appointed the Business Committee.

The University of Munich has offered a prize for the best thesis during the session of 1891–92, upon "Experimental and Clinical Investigations as to the Occurrence and the Diagnostic Significance of Leukocytosis."

Transmission of Tuberculosis by Railway Coaches.—Investigation has shown that four of ten railway coaches running between Berlin and Meran contained small numbers of tubercle-bacilli of only moderate virulence.

Adamkiewicz has been granted permission to utilize the material at the surgical clinic of Albert, at Vienna, in the pursuit of his investigations with a remedy for carcinoma.

The German Government has directed the establishment of a modern, well-equipped biologic station on Heligoland.

Docent Obrzut has been elected Professor Extraordinary of Pathological Histology in the Czech University at Prague.

Gram has been made Professor Extraordinary of Pharmacology at Copenhagen.

Cschiesch, of St. Petersburg, has been elected Ordinary Professor of Psychiatry at Dorpat.

A new Austrian Military Pharmacopœia is to enter into force in January, 1892.

Loeffler, of Greifswald, has been elected Ordinary Professor of Hygiene at the University of Marburg.

ORIGINAL ARTICLES.

FRACTURE IN THE UPPER THIRD OF THE FEMUR EXCLUSIVE OF THE NECK.[1]

BY OSCAR H. ALLIS, M.D.,
SURGEON TO THE PRESBYTERIAN HOSPITAL, PHILADELPHIA.

FRACTURES in the upper third of the femur are infrequent. In the aged, violence to this part is likely to fracture the neck, while in active middle life dislocations are not infrequently the result of violence that might otherwise produce fracture in the shaft. To what extent the frequency is modified by other injuries I cannot say, but the statement is verified by statistics. In the tables of Agnew's *Surgery* I find an average of 5 cases a year during a series of years when the Pennsylvania Hospital was the principal hospital in the city. Supposing Philadelphia to have had an average population of 500,000 during these years, this would give an average of 1 case in every 100,000 inhabitants. Even this would give no mean experience were such an injury to come annually to one surgeon, but when we consider that every city of such dimensions has a score of surgeons, it is not improbable that some of them might pass their lives without ever treating a single case.

I have called attention to this fact to show, first, how improbable it is that any single surgeon, writer or teacher should ever obtain a large *personal* experience upon this subject; second, to call attention to the statement of the most reliable authors that complete success in the treatment of this injury is not to be hoped for; that permanent *weakness* is likely to follow the most skilful employment of the most approved methods; third, to inquire into the nature of the deformity, the cause of the permanent "weakness," and the correctness of the methods of treatment; and, finally, with the hope that I may be able to stimulate investigation of a subject that has hitherto baffled the skill of our experts, that by a better and fuller understanding of it we may attain the success in this quarter that has so fully crowned the surgeon's labors in other fracture injuries.

In the study of the deformity that is so common after fracture, we rely mainly on the material of pathological museums. He who takes the trouble to investigate the specimens there collected, will find that in by far the greatest number union has taken place with angular deformity. I have not seen a single case in which the long axis of the shaft has been perfectly preserved. In the great majority, that which the surgeon calls shortening, and which in the living is ascertained by comparison of surface measurements, is found in the pathological specimens to be a somewhat complicated affair. In some instances there will apparently be great shortening, with but little overlapping, the loss in length being due chiefly to angular union. In the majority of cases, however, overlapping, angular union, with rotation of the individual fragments, exists.

The angular deformity seems to follow a law. In most instances it is forward and outward, or a blending of both. I have seen two specimens in which the angle of union was directed backward. Authors sometimes speak of angular projection inward. I have seen no instance of it. In most specimens the lower end of the short upper fragment is in advance of the upper end of the lower fragment. If we seek among authors for an explanation of this, we find a universal consensus of opinion that it is due to the action of the ilio-trochanteric muscles, and chiefly to the ilio-psoas. To bring this matter up for discussion, I will imagine a fracture to have occurred in the shaft of the femur, two inches below the lesser trochanter. The fracture is oblique, and all bony continuity is severed. We have now two fragments, *entirely independent* of each other, each free to follow any dominant force. The question is, What directions will the individual fragments take? We first take up the upper fragment. Here we have a portion of bone four or five inches long. The head of the femur forms a part of it, hence it is free to move, since it lies in a smooth, well-lubricated socket. This fragment is held in the socket chiefly by atmospheric pressure. Its motion is that of perfect circumduction within a large area of motion. It enjoys adduction, abduction, and flexion to a great extent, but extension —*i. e.*, deflection backward beyond the long axis of the trunk—is checked by the capsular ligament. The fragment is therefore free to move inward, forward, and outward, but is checked in backward movement. The position it almost invariably assumes in pathological specimens is forward or outward, and the alleged agency is the psoas muscle.

Let us now take up the lower fragment. It has no bony connection with the upper fragment. It, too, is free to follow a dominant force, and when it is remembered that to it are attached the strong adductors, the most natural conclusion is that the upper

[1] Read by title at the meeting of the American Surgical Association, held in Washington, D. C., September, 1891.

end of the lower fragment must be drawn inward and upward toward the pelvis. *Certainly, from an anatomical standpoint the fragments would be widely separated.* On the contrary, we invariably find them together. For the solution of this mystery we turn to the anatomy of the parts. It must be remembered that the point of supposed fracture is below the lesser trochanter. No fracture can occur here that does not traverse the tendons of many powerful muscles. Let us suppose the tendon of the great gluteus to have been traversed. (Fig. 1.) In such a case there would

FIG. 1.

Represents the upper third of the femur, sawn through so as to preserve a part of the tendon of the gluteus maximus as a hinge for the fragments. The tendon is represented below the great trochanter.

be a strong tendon hinge between the fragments, which, to a certain degree, would prevent independent movement and at the same time would exert a powerful influence upon both fragments. Such a hinge or bond of union would compel both fragments to move together in obedience to a dominant power. When, therefore, in the problem stated, I represented the fragments as *entirely independent* of each other, I misrepresented the facts, and the conditions of the problem must be re-stated:

Given a complete oblique fracture of the femur, two inches below the lesser trochanter, the fragments are *bound together* by a strong tendon hinge. Query: What direction will the fragments take? If we go to the pathological museum, the first specimen we encounter may present angular deformity forward and outward, with possibly rotation of the upper fragment outward. For the satisfaction of those who believe that the dominant influence is the ilio-trochanteric group of muscles, I will say that I can produce this deformity with artificial muscles in a dissecting-room specimen. But the question arises: Can the action of this group of muscles account for all the phenomena presented in specimens? I answer: No!—not a fourth part of it. A second question then arises: Cannot the same deformity be produced in an entirely different manner? I answer that it can. The mechanism of locomotion favors a totally different theory. All the powerful muscles of locomotion that pass from the pelvis to the knee either run parallel with a line that passes through the hip-joint and knee-joint (Fig. 2, A, B), or they pass internal to it. In a certain sense, the femur may be represented as a bent bow, and the muscles as the string of the bow; so long as the bow maintains its integrity, these muscles cannot approximate the knee to the hip-joint. But the instant fracture takes place, the fragments, free to move, yet *bound together* by a strong,

FIG. 2.

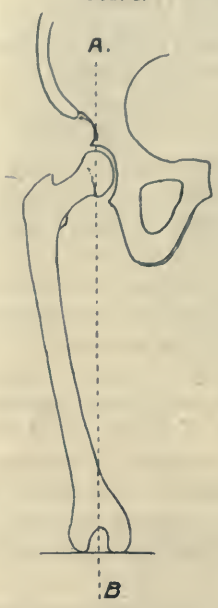

FIG. 3.

flexible tendon hinge, take the direction of least resistance, and that direction, when uncontrolled by external influences, is usually outward or forward. A study of Fig. 3, and of the anatomy of the part, will convince any unprejudiced mind that certain results are to be expected. First, the upper fragment is restrained from going backward by the ilio-femoral ligament; second, the curved shape of the femur and the bow-string principle of muscular action will tend powerfully to occasion, and be a guiding influence in the production of, both outward and forward displacement. Thus, in a dissecting-room specimen, with artificial tibio-pelvic muscles, I can produce the deformity that for centuries has been generally attributed to the ilio-trochanteric.

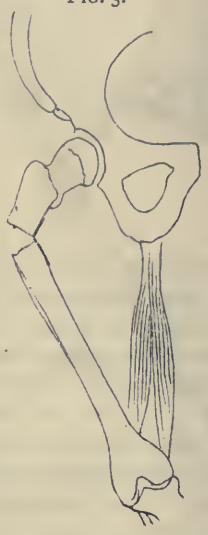
I have thus shown that the prevailing deformity can be produced artificially by forces dissimilar and widely separated. The question now arises: To which may it with greater justice be attributed? A contest of physical forces is involved; it is a question of mechanics, and, could all the elements of the problem be accurately stated, the mathematician could settle the question for us. As we cannot furnish exact data, we must content ourselves with approximation.

The problem remains: Which set of muscles is the more likely to produce the deformity—the ilio-trochanteric, or the tibio-pelvic? Or, in other

words: Which is the dominant fragment—the short upper, or the long lower one? Though apparently dissimilar, these are one and the same problem, and upon its satisfactory solution will hinge the choice of methods by the surgeon. In the solution of the problem, then, as to which set of muscles produces the deformity, we note, first, that all the ilio-trochanteric muscles (Fig. 4) act at a disadvantage. The

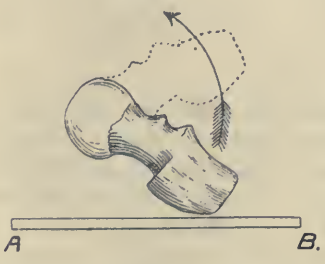
Fig. 4.

Fig. 5.



power acts on levers of the third class, and what increases the disadvantage is the fact that these muscles act upon the lever obliquely. Not so the tibio-pelvic muscles; their levers (after fracture, with a hinge) form what is known in mechanics as the "knee-joint," with unequal arms (Fig. 5), and the motive power is exerted to great advantage. Second, to produce the deformity, the ilio-trochanteric muscles must draw the short fragment upward with all the weight attached to the lower fragment, while the tibio-pelvic muscles can accomplish the same end by simply bending the "knee-joint" fracture. Third, if the upper fragment were drawn up by the psoas group, the lesser trochanter would be approximated to the pelvis in the direction of the contracted and shortened psoas muscle, and the fragment itself would be rotated outward. As a fact, in many specimens the upper fragment is so abducted that the distance of the lesser trochanter from the pelvis is increased, and the psoas muscle necessarily put upon the stretch. The truth of these statements can be demonstrated. First, as to rotation: If we take a normal femur, and lay it horizonally upon a table, with the anterior surface upward, it will rest as upon a tripod—*i. e.*, the two condyles will support it at one end, and the great trochanter at the other. (See Fig. 6, in which the great trochanter is represented as resting on a table, A, B. Note especially that the head of the femur lies an inch or more above the level of the table.) Now, in a specimen in the Gross cabinet, the upper fragment is so rotated inward that when the lower end rests on the condyles, the *head* rests on the table, and the trochanter is above the level of it. (See dotted line in Fig. 6.) If the normal femur is placed in the position of progression, the great trochanter lies posteriorly to the head. In the abnormal specimen referred to the trochanter lies in advance of the head. (See dotted outline, Fig. 6.) In this specimen, the trochanter minor lies posteriorly to the shaft when the femur is placed in the attitude of progression or support. This has placed the

Fig. 6.



tendon of the psoas muscle so strongly on the stretch that it has, through prolonged action, produced a groove on the *neck* of the femur. (See groove on neck in Fig. 6.) The presence of the groove is the result of the alteration in the axes of the fragments of the femur. It cannot be due to the attrition or pressure of the border of the acetabulum, for this is far out of reach, but must be due to pressure from the psoas tendon, which, in this perverted position in attempts at progression, is especially tense. Finally, if the upper fragment be regarded as dominant, then we have great difficulty in understanding how angular deformity, no matter how slight, directed backward, can occur. As already stated, I have seen this take place in two specimens. Authors even speak of angularity directed inward. On the theory that the long lower fragment is the dominant fragment, these exceptional positions can be explained. This, the long fragment, is the one the surgeon treats, and as the upper fragment is hinged to it, pressure unduly exerted may at times produce posterior or internal angularity.

Thus far I have endeavored to show that angular deformity would follow shortening—*i. e.*, the approximation of the knee-joint to the hip-joint after fracture of the shaft with *hinge* connection. I have now something both new and strange to offer. It is this:

Extension, no matter in what direction, will also produce anterior angular deformity. The principle on which this proposition rests is demonstrated as readily as is that already enunciated. Let any one take a card (Fig. 7), cut it so as to represent a carpenter's square; make a hole in each end; attach a weight to

one, and suspend it from a nail. So long as the integrity of the card is preserved, there will be an antagonism between the rectangular path of resistance and the direct path of the force represented by the weight (Fig. 7, A, B). Now cut the card, hinge it, and again apply the weight. The lower fragment being free to move, takes the path of the extending force,

FIG. 7.

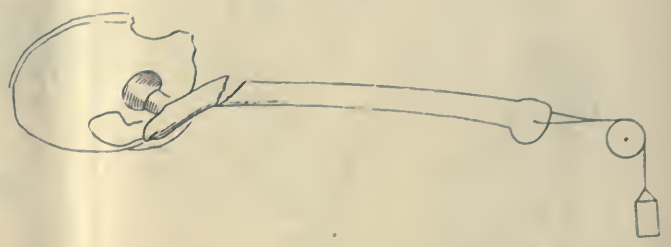
FIG. 8.

while its attachment to the upper fragment, not being in its axis, but extra-axial, so acts upon it that nail, hinge, and weight lie in the line of traction. (C, D, Fig. 8.) If the practical surgeon will stop a moment and compare the effect of traction *after* section with the effect *before* section, he will find that the card is distorted in both its parts. The lower fragment is turned away from its normal axis to conform to the line of traction. The lower end of the upper fragment turns abruptly from its normal bed and tilts inward. Thus, with a piece of cardboard the truth of the second proposition, that extension necessitates angularity, can be verified.

That which can be demonstrated with a card can with equal clearness he demonstrated upon a dissecting-room specimen. All that is needed is a shaft that arches forward, a head and neck obliquely attached to it, and a hinge between the fragments. Whether such a specimen be suspended, or extension be made horizontally, the angularity will be the same. Glancing at Figure 9, the first impulse would be to lift the lower fragment, and then make extension; but, I repeat, the same degree of deformity persists, and my proposition holds good that extension, no matter how exerted, must produce deformity.

DIAGNOSIS.—This requires us to locate the point of fracture and ascertain its characteristics—*i. e.*, whether oblique or transverse, etc., and if oblique, the direction of breakage. We must therefore ascertain the degree and extent of local damage;

FIG. 9.



whether the hinge is short or freely torn; whether the upper fragment is flexed, abducted, or rotated; the degree of flexion, abduction, and rotation; the cause of the malposition, and the agencies that oppose coaptation. It is necessary to know the direction of the axes of the fragments, and whether the proposed treatment corrects the existing deformity. It is necessary to estimate the nature of the "shortening," and without data to learn to what it is due. It is necessary to estimate the relative amount of shortening without a record of the conditions of the limbs before fracture. *It is necessary to do all this with a limb that we cannot span with our two hands, and through a padding of flesh from one to four inches thick!*

TREATMENT.—Erichsen, with a degree of candor that does him great credit, says that, adopt whatever plan we will, the result will not be satisfactory. That this is the experience of all surgeons, I dare not say, but I believe that few—very few, indeed—can dissent from it. An inquiry into the defects of treatment, therefore, should be an earnest, persistent study.

Probably the most extensively applied treatment of the day is horizontal extension. Its popularity consists in the fact that in no other way can extension be so readily and certainly applied, and upon the theory that by properly regulated extension the upper fragment can be drawn down and approximated to the lower fragment. The theory is based on faulty reasoning, and clinical results bear me out in my statement. Extension cannot draw down the upper fragment, even in a dissecting-room specimen. The reasons for this I have already given.

To overcome the tendency to anterior tilting of the upper fragment, the double inclined plane was devised. Its theory was to adjust the tractable lower fragment to the intractable upper one. Its defects are—first, that no adjustment can take place so long

as there is shortening; and, second, that all attempts to overcome shortening by extension necessitate angular deformity. The double inclined plane has no advantage whatever over horizontal extension, both being equally unscientific and disappointing.

Every method of treatment hitherto devised has been directed chiefly to the lower fragment. That

Fig. 10.

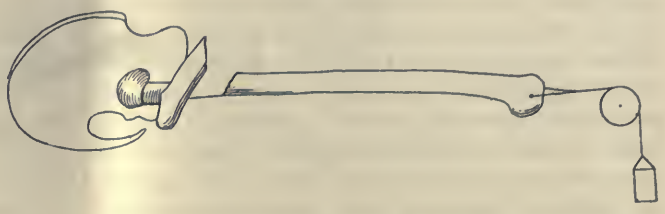
Fig. 11.

such a course has done all for human suffering that it can possibly do is probably beyond dispute. That such a course has produced untold deformities is equally as true, and equally as demonstrable. If we glance at Figs. 10 and 11, we note that the instant that fracture takes place and all parts feel the influence of the extending weight, we find both fragments diverted from the normal position, and the reason is that the weight through the hinge acts only upon the upper fragment. It should be especially noted that while the upper fragment (Fig. 10) seems to be greatly diverted, the lower is equally so.

The length of the hinge or bond of union between the fragments should be carefully noted. If it be a close, short hinge, it will have more control over the upper fragment than if it be a long, loose hinge. Note particularly how much more the upper fragment is tilted in Fig. 11 than in Fig. 10. This diagram (Fig. 11) should be most suggestive to the practical surgeon with a recent fracture to deal with. With the upper fragment tilted up, no matter from what cause, with strong, contracted ilio-trochanteric muscles, goaded by pain, and now acting at the greatest possible advantage upon the short, flexed upper fragment, the surgeon attempts to draw it down by extension! (Fig. 12.) Extension—and through what medium, I ask? Not upon the fragment itself, because the fracture forbids this, but *extension solely through a loose ligamentous extra-axial hinge!* As well attempt to stay the shadow of a passing cloud!

A study of the effect of traction in both these figures reveals two important facts: first, that both fragments are diverted from their normal axes; second, that the control of the upper fragment will vary with the length of the bond or hinge. The

Fig. 12.



degree of axial displacement and its ulterior effect must be especially noted. Authors have from very early times ascribed the resulting "weakness" in the limb to a weak bond of union. The real cause of weakness is the altered relation of the head to the socket, and of the condyles to the tibia. In Fig. 13 I have, by means of a cross-bar at the lower extremity, represented the plane of the articulation

Fig. 13.

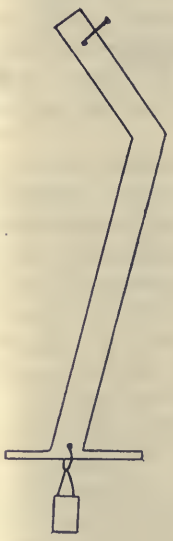


Fig. 14.

In Figs. 13 and 14 the cross-bar at the bottom represents the transverse axis of the knee-joint. After fracture that axis is greatly distorted when angular union takes place (Fig. 14).

at the knee-joint. Now contrast the altered plane of Fig. 14, after fracture, with that of Fig. 13. Could a person walk on such a limb? Experience and a knowledge of the laws of progression answer, No. If in such a limb the foot is placed in the attitude for locomotion, the head of the femur will be in a most unnatural position, while if the head is placed normally in its socket, the foot cannot bear the weight of the body.

I have condemned the various methods of treatment as unscientific and incapable of yielding satisfactory results. I have condemned them because no method of treatment hitherto devised is capable of controlling the upper fragment, and only the treatment that begins with fixation of the upper fragment has a rational basis for success.

The typical treatment, the only one that can insure perfect success, is the open method. A free incision would permit the fingers to be passed down to the fragments, and actual tactile impressions are the only assurance of accurate reposition. Fixation, then, with carpenter's screws would insure a useful limb. These I have used for years and know their superior value. I drive the head of the screw to the surface of the bone and leave it undisturbed until it is forced from its bed into the surrounding tissues by reparative changes in the bone. This usually occurs in the course of two months. Then I pick it out and the sinus soon heals. A less heroic, but far less certain and less effective plan, would be to thrust a strong, sharp-pointed awl through the skin to the femur, and with this held down, the lower fragment could be adjusted, a firm pad placed over the upper fragment, and the whole placed in a plaster-of-Paris splint. The temporary use of a steel pin would not increase the danger to the patient, but the pin to be of any service must be kept in place for weeks. That this would be without danger, I am not prepared to say.

In justification of the open method, I would cite the numerous cases of osteotomy performed to correct deformity in bone, that can now be referred to. Osteotomy to correct angular deformity is still sufficiently frequent, not only to justify the operation, but to guarantee its safety. A Swede came under my care who, though thirty weeks had passed since a fracture in the upper third of the femur had taken place, was still unable to walk without a cane. Angular deformity, with shortening of less than half an inch, was the cause of the "weakness." I cut down upon the bone at the point of juncture, sawed out a V-shaped section, secured the fragments with a screw, and the man recovered to earn full wages at hard, manual labor.

In illustration of the inefficiency of traction to bring down the upper fragment, and of the necessity of fixation of the fragments by means of a screw or some permanent method, I will cite a case of compound fracture of the upper third of the femur, that was treated at a Philadelphia hospital. Dr. R——, the house-surgeon, first made extension, but found that it did not influence the upper fragment. Then passing his fingers into the wound, he held the upper fragment while the lower was approximated to it by extension and manipulation, and finished the dressing with a strong, superimposed pad. So long as his fingers were upon the fragment he secured perfect approximation, but this he could not perpetuate by means of splints, and union took place with an inch of shortening and marked antero-lateral angularity. The splint used was the inclined plane.

SUMMARY.

After fracture of the shaft, the fragments are bound together by a hinge.

The hinge will be short if the vulnerating force was only sufficient to break the bone.

If the hinge is short, overlapping can only occur to a very limited degree. In all such cases the "shortening" will be due to angular displacement.

If the vulnerating force is greater than necessary to merely fracture the bone, the unexpended force will tear the hinge freely.

When the hinge is loose, overlapping, with or without angular deformity, is possible.

The shorter the hinge the greater will be the control of the upper fragment, through the agency of the lower.

Traction on the lower fragment under all circumstances is incapable of restoring the long axes of the broken bone.

If the hinge is short, traction will draw down the upper fragment, but cannot efface the anterior angular tendency.

If the hinge is long (Fig. 12), traction will exert but little influence upon the upper fragment.

Traction in the oblique direction has no advantage over horizontal extension.

The so-called "weakness" after fracture of the femur is not due to deficient bone-repair.

"Weakness" is greatest when due to angular deformity with rotation of fragments.

Angular deformity, with rotation of fragments, compels both hip and knee to assume abnormal relations to the trunk.

Shortening, due to overlapping, *without* angular deformity or rotation of fragments, is no barrier to heavy, manual labor.

Treatment directed to the lower fragment is the probable agency in causing rotation in the lower fragment.

No surface treatment can *insure* a useful limb.

Osteotomy has corrected many a faulty union after months of waste time.

The conversion of a sealed (simple) fracture into an exposed (compound) one offers the only possible means for accurate diagnosis, and the only possible method of rational treatment.

Patients and surgeons who stop short of this procedure must compromise with best results.

1604 SPRUCE STREET.

LAPAROTOMY FOR INTESTINAL PERFORATION IN TYPHOID FEVER.

With the Report of a Successful Case.

BY WELLER VAN HOOK, A.B., M.D.,

PROFESSOR OF SURGICAL PATHOLOGY AND BACTERIOLOGY, COLLEGE OF PHYSICIANS AND SURGEONS; PROFESSOR OF SURGERY, CHICAGO POST-GRADUATE MEDICAL SCHOOL; SURGEON TO COOK COUNTY AND CHICAGO CHARITY HOSPITALS.

Shall laparotomy be performed for intestinal perforation in typhoid fever? This is a question that, in the seven and a half years that have elapsed since Leyden first answered it affirmatively (May 24, 1884), has elicited a variety of affirmative and negative,[1] decided and qualified, confident and doubtful, bold and timorous replies from both physicians and surgeons, first in Germany and afterward in England, Ireland, America, France, Japan, Australia, and Russia. It is strange, nevertheless, that a question involving the only promise of help for 5.7 per cent. of all those dying of typhoid fever[2] should not have excited even more interest and discussion. The decision of the question demands a preliminary reply to the question of the efficacy of other modes of treatment. This inquiry is the more easily conducted because the indisputable spontaneous recoveries after perforation reported by Murchison, Griesinger, Buhl, and others, are so exceedingly rare that they are reckoned among the curiosities of our observations, and because no medical writer, so far as can be ascertained, has offered the least ground for hope from the employment of medical treatment when this pathological accident has occurred. Louis,[3] who has recently studied this point, refers to Ziemssen (1888), Spilmann, and Garszinotty and Jaccoud as authorities, and it would be easy but superfluous to increase the number of distinguished and unanimous observers by a reference to American and English authors. The opium treatment of peritonitis has of late years been so freely combated by advocates of flushing, drainage, and free catharsis that it will soon be definitely reckoned among the relics of medical medievalism.

The most important objections raised against laparotomy in typhoid intestinal perforations are that the patient's tissues are degenerated, offering unfavorable conditions for healing, and that the typhoid fever is still in progress and must be recovered from, in addition to the shock and traumatism of the operation, and in addition to the peritonitis. That healing takes place in the ulcerated bowel when sutured is easily proved by the post-mortem examinations made in the fatal cases operated upon, as well as by the mere fact of recovery in the cases that have pursued a favorable course. That the operation itself adds to the danger by consuming the patient's limited stock of vital energy through shock, traumatism, and the damage done by anesthetics is not to be gainsaid. But I maintain that laparotomy, performed as I shall describe, does not necessarily kill by itself, and that it is not more dangerous *per se* than other operations occasionally and successfully performed in the course of typhoid fever and other febrile diseases. It is not the operation that destroys life; it is the violent suppurative and putrefactive peritonitis set up by the feces poured out into the abdominal cavity. The quantity of feces escaping is the less important, because even a small amount is sufficient, by virtue of the multiplication of the mixed varieties of bacteria in the exudate, to fill the belly in a few hours with quarts of stinking, virulent pus. A remedy for perforative peritonitis in typhoid fever, outside of mechanical removal of the feces and gas from the abdominal cavity, mechanical closure of the hole through which it escaped, and provision for constant mechanical removal of the peritonitis-exudate, is, in the present state of our knowledge, rationally inconceivable.

Shall laparotomy be performed in all cases? This inquiry, in its categorical form, admits easily of a negative reply. It is only when we come to set down hard and fast rules for discrimination that differences of opinion arise. Thus, in a paper discussing this point before the American Surgical Association in 1888, J. Ewing Mears drew the conclusion that surgical interference is not justifiable when the fever is at its height; and, secondly, that in mild cases, when perforation occurs at the end of the third week, laparotomy may be performed. With these conclusions Dr. B. A. Watson agreed. Dr. Bontecou, who had twice operated, dissented, and held that the indication for laparotomy is imperative.

To be brief, however, the horns of the dilemma are—the one that the patient will almost certainly not recover without the operation, the other that the patient may recover with the operation. We are therefore not any longer in a position to reject laparotomy, except when the patient is actually in a moribund state. Considerations of policy are to be set aside by placing the responsibility upon the shoulders of the patient or his friends, while the thought of a broken record of recoveries from laparotomy is unworthy of honorable consideration. Hoelscher,[1] who studied the records of 2000 lethal cases of typhoid in the Munich Hospital, states that no deaths from perforative peritonitis are recorded as occurring in the first two weeks of the disease. Hence all the perforations occur either at the height of the disease (in the third week) or during deferves-

[1] Potain: Gaz. des Hôpitaux, 1891, lxiv. 621.

[2] Hoelscher (Münchener med. Woch., 1891, xxxviii. 43) found 114 deaths from perforation in 2000 deaths from typhoid fever.

[3] Progrès Médical, 1890, 2e sér., xii. 572.

[1] Münchener med. Woch., January, 1891, p. 43.

cence. We may therefore count that in case of recovery from the peritonitis the patient in some of the cases will have to pass through one-half of the entire course of the disease. The patient whose recovery is here recorded went through a typical course of typhoid fever, which ended two and a half weeks after the operation.

Hence it would seem that the stage of the disease, though perhaps slightly modifying the chances of recovery, does not in the least degree alter the responsibility of the physician. If the perforation occurs early, the patient's strength to withstand the peritonitis has not been exhausted by the disease; while if the accident takes place later, the patient, when he has survived the peritonitis, has but little of the typhoid to combat.

Collapse is a contra-indication to operation only when it is apparent that the condition itself is the immediate forerunner of death. Reaction must usually be sought before the operation is begun; but we must remember that hot flushing of the abdomen will often revive the patient.

The physician's duty, when facing such convictions, is manifestly clear. In taking charge of every case of typhoid fever, he is imperatively obliged by conscience to be ready to assume or to transfer to another the responsibility of laparotomy in case of perforation—just as in cases of croup he must, if necessity arise, be ready to mechanically admit air into the lungs. Furthermore, in view of the fact that early laparotomy may cut short the peritonitis, it is equally his duty in every case to inform the nurse of the symptoms of perforation, in order that, should the accident occur, he may be called instantly.

The diagnosis of intestinal perforation in typhoid fever may be very easy or very difficult. We have not time to discuss it fully; it must suffice to mention the chief symptoms that occur in typical cases. The presumptive evidence is in favor of a diagnosis of this accident when typhoid fever can be clearly diagnosticated and positive symptoms of perforation are present. Sudden, violent, abdominal pain, usually in the ileo-cecal region, is more conclusively diagnostic when it is of a cutting or tearing character, and when violent peristalsis, imprudence in diet, or improper posture has given an opportunity for local, mechanical injury. Examination within the first two hours will usually disclose tenderness as one of the chief distinctive features. But absolute disappearance of liver-dulness is to be regarded as a more crucial test, indicating the presence of free gas in the peritoneal cavity. This sign may be absent on account of the fact that only fluid matter has escaped from the bowel, or because, though gas has escaped, the abdominal walls are not separated from the liver on account of old adhesions. If much free fluid has escaped, or if peritonitis-exudate is present in quantity, it may be demonstrated by percussion, with the patient in different positions. Tympanites, if not already present, will soon follow the onset of peritonitis. The drawn, anxious face of the patient is covered with cold perspiration, and, as a rule, further evidences of shock are furnished by cold extremities, subnormal temperature, and a small, rapid pulse. When reaction takes place, the temperature rises, and the pulse increases in frequency, becoming, at the same time, quick and wiry. The signs of peritonitis soon increase in number, the knees are drawn up, the abdominal walls are tense, the tenderness and pain are great, and vomiting, often stercoraceous, is usually observed. Rarer symptoms are sometimes noted. Thus, Tschudnowsky heard in one case, on auscultation, a gurgling, amphoric murmur, synchronous with respiration, which was thought during the life of the patient and was found at the autopsy to be due to gas and fluid running in and out of the opening.

It is most important to make a diagnosis before peritonitis has become violent and general, since every minute of delay adds to the danger to life. And I would especially insist that while the presence of general peritonitis increases our obligation to operate, it is unnecessary and wrong to wait for symptoms of inflammation before opening the abdomen; for absorption of the intestinal contents through the peritoneum is probably alone sufficient to destroy life. It should further be borne in mind that while preparations are being made for laparotomy, under the most favorable circumstances requiring from thirty to sixty minutes, the patient may begin to exhibit more positive symptoms of the occurrence of the accident.

CASE I.—Miss S., aged thirty-one, height five feet six inches, weight one hundred and forty pounds, was seen for the first time by Dr. John Fisher, June 24, 1891. The patient, who had previously enjoyed perfect health, had been ailing with headache and chilly sensations for a week. Two days previously she had had slight chilly sensations; the temperature at the time of the first visit was 103°, the pulse 112 per minute, and the tongue dry. A diagnosis of typhoid fever was made. Small doses of antipyrin relieved the headache, and slightly reduced the temperature. The patient was kept on fluid diet. On the sixteenth day the temperature seemed normal, and at the end of the third week she began attending to light domestic duties. After having been apparently devoid of fever for fourteen days, the thermometer not being used, she had a chilly sensation on July 17th. On the following day, Dr. Fisher found a temperature of 104°, a pulse of 120 per minute, severe headache, and much prostration. Dr. Fisher diagnosticated[1] a relapse of

[1] There was no evidence of dysentery or other bowel trouble.

typhoid fever, and instituted the same treatment as before. On the seventh day of the supposed relapse, the bowels not having moved for thirty-six hours, an enema of warm water was given. This, in a few hours, was followed by two passages and by a third at four o'clock A.M. of the eighth day. At five o'clock she was attacked suddenly with great pain in the ileo-cecal region, followed by a cold sweat, coldness of the extremities, and an excessively pinched and anxious expression of countenance. Dr. Fisher saw the patient at seven o'clock, and found a temperature of 105.5°, with a quick, wiry pulse of 126. The pain almost ceased soon afterward, without the administration of anodynes. Dr. Fisher recognized the symptoms as those of intestinal perforation. On seeing the patient with Dr. Fisher at nine o'clock, I confirmed his diagnosis by consideration of the following points:

First. The history of the case pointed indubitably to the existence of typhoid fever.

Second. The mechanical explanation of a perforation was supplied by the fact that active peristalsis had been excited by the enema.

Third. The symptoms of anxiety, pain, and shock were typical.

Fourth. The objective symptoms already noted were supplemented at that time (four hours after the accident) by a rising temperature (106°), and an increasing pulse-rate (132), plus the typical signs of peritonitis, viz., tympanites, tension of the abdominal muscles, and tenderness upon pressure over the ileo-cecal region.

On account of the lack of the friends' consent, the operation could not be begun until 2.40 P.M., when I opened the abdomen. The incision, in the median line below the umbilicus, opened the peritoneum through an extent of about two and a half inches, which afforded ample room. No gas escaped (the liver-dulness had not been altered), but more than a pint of fluid feces and exudate, mixed with flocculi of lymph, was removed. On gently pulling out coils of small intestine in the direction of the ileo-cecal valve, numerous ulcers—one or two of them almost perforating—were seen.[1] Flocculi of lymph over the surface of the inflamed bowels indicated the points where the peritonitis was oldest and most violent. That the peritonitis was general was demonstrated by the facts that all the coils seen were injected and dull-looking, and that the fecal matter was freely circulating in the peritoneal sac. When two or three coils had been drawn up and examined, the opening was found. It was irregularly circular, and about two millimeters in diameter. While the coil was held up (it being the only part of the intestine now exposed), the feces were carefully sponged off with sterilized gauze, and the opening closed with three longitudinal rows of interrupted Lembert sutures. The gut walls were so thick and so brittle from edema that three rows were thought necessary to insure strength. I did not look for other perforations in this case, because it seemed that the woman had a remote chance of recovery if she could be quickly put to bed. Consequently, not more than two and one-half feet of intestine altogether were exposed. The abdominal sac was now thoroughly and carefully washed out with nearly half a wash-boilerful of hot, sterilized water. The omentum was carefully drawn over the injured coil of intestine, and sutured to the mesentery. A large drainage-tube was passed to Douglas's cul-de-sac, and the remainder of the abdominal wound closed. The patient was much exhausted at the close of the operation, but was not in collapse, although the pulse was small and rapid, and the temperature high. On the following morning, at 9 A.M., the abdomen was enormously distended, and everywhere tender, and the patient looked moribund. Enemas of an ounce each of magnesium sulphate, glycerin, and water had been given three times, beginning two hours after the operation, once with a double dose, without effect. At eleven o'clock, however, the bowels began to move, and she had ten or twelve watery passages, after which she began to improve. The tympanites diminished, the pulse improved, and the amount of fluid aspirated from the tube was much diminished. The temperature remained at 103° for four or five days, when the symptoms of peritonitis began to disappear. The tube being withdrawn, the wound healed, and the symptoms of typhoid, running a normal course by a typical defervescence, ended in two and one-half weeks. The patient is now enjoying perfect health.

CASE II.—A. S., Bohemian, twenty-nine years of age, entered Cook County Hospital, June 12, 1891. She was stupid and dull, presenting all the classical symptoms of typhoid. No previous history could be obtained. The course of the disease was typical and regular until the morning of June 28th, when the patient got up and walked unobserved to the bath-room. She was taken back to her bed and immediately seemed to be in great pain. When seen by the house-physician the tense, rigid, distended abdomen, with loss of liver-dulness, pointed to perforation. Her general condition was that of collapse, the pulse being rapid and thread-like, and the skin cold and clammy. On being transferred to the surgical department I concurred in the diagnosis and opened the abdomen, seven hours after the perforation occurred. The peritoneal sac was found filled with thin, liquid feculent matter. The patient becoming rapidly worse despite stimulation, the operation was not completed. The patient died a few minutes later. At the autopsy an oval perforation was found in the ileum, 18 inches above the *caput coli*. The visceral peritoneum around the perforation was adherent for three-fourths of its circumference, the remaining portion having probably been loosened by the traction occasioned in walking. A second ulcer was found opening into a small abscess-cavity within the peritoneum. Adhesions shut it off completely from the general serous sac.

CASE III.—John Connell, thirty-five years of age, walked into the Cook County Hospital, October 30th, at 5 P.M. His temperature was 102°; pulse

[1] These ulcers were so numerous and so characteristic, as seen through the translucent bowel, that they must have been of comparatively long standing. I am strongly of the opinion that the temperature, especially of afternoons, had not been normal before the apparent relapse.

120, being small, soft, and irregular. The patient looked pale and haggard; his eyes were sunken; his abdomen was moderately distended, rigid, and extremely sensitive to pressure all over. His mind was dull. A diagnosis of probable typhoid fever was made. Fourteen hours later it was found that the liver-dulness was absent, and as the patient was in collapse a diagnosis of perforation was made. The patient being transferred to my service, the abdomen was opened and a perforating ulcer found about 12 inches above the ileo-cecal valve. The opening was closed by a double row of Lembert sutures. The abdominal cavity was filled with fluid feces and exudate. The peritoneal sac having been washed out and drained, the patient was put to bed in fair condition and lived fourteen hours. The autopsy showed general peritonitis. The perforation had been completely closed.

The *statistics* of the operation are as follows:

1884 (Sept.). Mikulicz: 4 cases, with one recovery, though unfortunately the diagnosis is doubtful.

1885. Lücke: resection, death.

1886. Escher: 1 case, recovery; but the case is regarded by Louis as one of appendicitis.

1886. Greig Smith: 1 case, doubtful diagnosis, death.

1886. Bartleet: 1 case, death.

1887. Bontecou: 1 case, death.

1887. Morton: 1 case, death.

1889. Bontecou: 1 case, death.

1889. Senn: volvulus and perforation, 1 case, death.

1889. Hahn: 2 cases, death.

1890. Kimura: 1 case, death.

To these 15 cases are to be added that of Taylor,[1] 1891, and the three reported here, making in all 19 recorded laparotomies, with four recoveries. The case of recovery of Mikulicz was stated by the operator to be of doubtful diagnosis. That of Escher was probably a perforation from appendicitis. Taylor's case should not be counted, as it was operated upon ten days after the onset of symptoms, and is, furthermore, not demonstrated to have been a typhoid perforation. If we include all the doubtful cases, the present recovery is, as appears from the literature at command, the seventeenth case and the fourth recovery. If we include only closely diagnosticated cases it is the twelfth case and the first recovery.

The *technique* of the operation, which has for its object three chief ends—closure of the perforation, cleansing of the peritoneum, and the institution of drainage—must be modified to meet the obvious primary considerations of minimum consumption of time, minimum manipulation of intestines, and minimum administration of anesthetics, together with maximum accuracy in closing the perforation and maximum care in the toilet of the peritoneum. The incision should be median, should lie at first below the umbilicus, and should at first be from two to four inches long, depending upon the thickness of the abdominal walls. If found desirable, its length may at any time be increased with the scissors. In the majority of instances the perforation is within two or three feet of the cecum, usually in the ileum, rarely in the colon. The perforation should first be sought by inspecting the presenting coils of the small intestine. In some cases (in two of my own) the perforation was found in this way without drawing out more than two feet of intestine. After examining these few coils, the appendix and small intestine, beginning at the cecum, must be carefully and completely examined on account of the great probability of finding the opening in one of them. The coils must be carefully drawn out with the finger tips, all stretching and forcible dragging being specially avoided for fear of tearing new holes through the ulcerated walls. When a small coil has been examined, it should be quickly and gently replaced. It must be remembered that quantities of "plastic lymph" usually cover the bowels where the peritonitis is oldest. They will often guide the operator to the opening, sometimes obviating the necessity of a systematic search. Occasionally the perforation will be found wholly or partly hidden by such a mass. If the operator has begun at the cecum he should continue to search successive coils of the small bowel until the perforation is found, or until the duodenum is reached. The colon may next be examined. Success in this operation will, however, rarely be obtained when so much manipulation has been resorted to. But, fortunately, it will be but very rarely required. The use of the test for perforation by gas-insufflation will not be resorted to, because in peritonitis with paretic bowel-walls the gas is difficult to remove; because it may itself make openings in the bowel, and because the intense artificial tympanites may interfere with respiration.

Once the perforation has been found, its treatment demands much care. In one recorded case, that of Lücke, the intestine was resected, but this can but rarely be required, since as a rule the perforation is only one or two millimeters in transverse diameter. It is indicated when the bowel is extensively ulcerated so that stitching is impossible. Orth tells us that the ulcers are almost always on the free border of the intestine. In this case the gut should be held up by an assistant and the opening quickly closed by a double row of interrupted Lembert sutures. The ulcer should not be trimmed. It does no good to trim it, because the frayed edges are turned inward and the trimming is a disadvantage as it takes time. The line of sutures should

[1] Lancet, 1890, i. 961.

be parallel with the long axis of the bowel. Interrupted sutures must be used because the intestinal walls are so edematous and soft that continuous sutures tear out in places, loosening the whole line.

When the first opening has been satisfactorily closed, shall we search for another? It would be erroneous to make a protracted search for a second opening, if one had been fortunately found, since, as a rule, only one opening exists. Still, as most perforations occur near the ileo-cecal valve, it would be advisable to examine the bowel near the cecum, especially if the first opening, by occurring in that region, rendered easy such an exploration.

The perforation having been closed, the coil of intestine in which it occurred is gently held by an assistant at one end of the wound until the peritoneal sac is carefully cleansed. This should be done preferably by means of a thick stream of sterilized salt solution, six-tenths of 1 per cent., at a temperature of from 105° to 112°. In emergencies boiled water will answer. The wound-edges should be held up and the abdomen freely and frequently flushed until the washings are clean. This part of the work is essential and can be accorded as much time as is necessary, especially since the action of the hot solution is stimulating and tends to prevent shock.

The coil of bowel that has been held by the assistant during the irrigation is now again examined to see that the stitches are in place and that the lumen of the tube is not dangerously diminished. The omentum is now drawn down over the coil of intestine and without tension fastened to the mesentery. Dr. F. B. Robinson has informed me that in his experiments on dogs he found that, unless the omentum is fastened by two sutures placed at its margin, it has a tendency to roll up. The hint may be taken in the disposal of the omentum over the coil of intestine in which the perforation has occurred.

Drainage is best secured by means of a large glass tube passed to the lowest part of the pelvis. The outer end of the tube is so arranged that it can, without disturbing the patient, be easily kept dry by suction every half hour. The nurse must be carefully instructed how to perform this important duty.

If the patient is not in a state of collapse, a rectal injection of an ounce each of magnesium sulphate, glycerin, and water should be given to prevent peritoneal exudation by producing a few watery passages.

The anesthetic should be chloroform, on account of its rapid, easy action, its slightly detrimental effect upon the lungs and kidneys, and its tendency to excite but little vomiting. Administered to full anesthesia until the perforation is found, it may be given in less quantity while the intestine is being sutured. A skilful assistant will, after giving a hypodermatic dose of morphine, conduct the entire administration with only a few drams of the drug, watching the steps of the operation to see when the different degrees of anesthesia are required.

The relation of the after-effect of the operation to the typhoid fever must be looked upon as a subject for serious study. Yet the operative danger is deeply overshadowed by that of the peritonitis, which we must expect to prove fatal in very many cases, even when rational treatment has been carried out. It is only by rapid, skilful, but above all by very early interference, that we can hope to materially reduce the death-rate from perforative peritonitis in typhoid fever.

Conclusions.

1. There is no rational treatment for perforation in the course of typhoid fever, except laparotomy.
2. The indication for laparotomy when perforation occurs in typhoid fever is imperative.
3. The only contra-indication is a moribund condition of the patient.
4. Collapse is often at least temporarily relievable by hot peritoneal flushing.
5. The stage of the fever is not to be considered as an indication or as a contra-indication for laparotomy.
6. The severity of the typhoid fever is alone not a contra-indication.
7. Early laparotomy offers the most hope.
8. The symptoms of peritonitis should not be awaited before operating.
9. In taking charge of all typhoid fever patients, it is the physician's duty to be ready, in case of perforation, to perform laparotomy.
10. The published statistics of laparotomy for this condition are strongly in favor of operation.
11. The technique, though not complicated, demands much thoughtfulness, acquired dexterity, great rapidity, and thoroughness.

ERYSIPELAS AND ACUTE SUPPURATION IN THE MIDDLE EAR.[1]

BY H. V. WÜRDEMANN, M.D.,
OF MILWAUKEE, WIS.

IN a thorough search of the literature of the subject at my command I can find but little mention of erysipelas in connection with ear disease. With the exception of two "traumatic" cases, reported by Roosa,[2] occurring after a mastoid operation (which were probably due to this procedure), and that of dermal erysipelas of the auricles, nothing can be found. The latter complication is not

[1] Read before the Rock River Medical Society at Neenah, Wis., July 28, 1891.

[2] Roosa, St. John: Dis. of the Ear, 1885, pp. 521, 522.

uncommon, cases being sometimes seen in general practice.

The text-books generally speak of an extension of the cutaneous lesion to the larynx, and one of them[1] refers to the implication of the pharynx. Such authors as Bosworth,[2] Seiler,[3] and Gottstein,[4] make no mention of its arising in the pharynx or nasal membranes, and all works that I have consulted are silent upon its extension to or implication of the middle ear. Charles W. Allen,[5] in an able article upon the treatment of the disease and a report of fifty cases, does not refer to any of these complications. This writer states: "It is probable that every case of facial erysipelas arises from some local solution of continuity in the skin or adjacent mucous membranes. There is probably no such thing as idiopathic erysipelas. We simply call some cases 'idiopathic' or 'genuine' when we fail to find the point where the micrococci have entered." Now, the following cases would ordinarily be termed "idiopathic," but in the first the mycotic process probably originated in the pharyngeal walls, as a result of an operation; in the last case an initial lesion may have been caused by the act of picking the nose; and in the second, possibly the point of entrance was an abrasion from a pipe or cigar, as the patient acknowledged that he was a heavy smoker, and the disease began on the mucous surface of the lower lip:

Case I.—A bookkeeper, twenty-nine years of age, applied to me for treatment of his left ear, February 20, 1890. I found the tympanum filled with a serous secretion, which could be easily cleared away by inflation. After a few treatments he was discharged as cured, but again appeared April 29th, with pharyngitis and slight earache. A post-pharyngeal abscess was diagnosticated and incised, liberating three or four grams of pus. The pharyngeal tonsil, being hypertrophied, was subsequently removed by guillotine-forceps. Some relief was obtained by the operation, but two weeks later he returned with earache, with the drum red and inflamed. On the next day the membrane was bulging, and I performed paracentesis, releasing bloody pus from the cavity of the tympanum. The pain remained so intense that an opiate was administered, the patient ordered to bed, and leeches applied in front of the tragus. On examination of the pharynx its walls were found greatly tumefied, and of a dusky-red color. Ice was given the patient to suck, and boric acid and cocaine spray applied to the pharynx. The ear was dressed antiseptically.

On the morrow the left nasal cavity was swollen shut, the temperature 103° at my morning visit, and 105° in the evening; pulse 101. Erysipelas was suspected, as the anterior nares were dusky-red, and in the morning, when Dr. W. H. Washburn (the family physician) was called, the diagnosis was corroborated. The roseola now spread from the nostril as a focus over the entire face, swelling the eyelids, extending to the scalp, neck, and the auricles of both sides, within four days. At this time the temperature ranged from 102° to 106°, and the pulse was weak and rapid. The man retained little on his stomach, was delirious, at times having maniacal excitement and at others being almost comatose. Several consultations were held with other physicians, but the supportive and stimulant treatment instituted by the family physician was continued without much change. The ear was cleansed regularly, and dressed with boric acid powder. On the fourth day the pus was very thick and offensive, and continued so for a week or more. May 20th was the critical day, the fever suddenly abating, leaving the patient very weak. One relapse of erysipelas occurred from the 25th to the 29th. The patient gradually rallied, the otitis pursuing the usual course. The ear stopped discharging at the end of the sixth week, and the perforation closed. On June 28th the watch could be heard at 100 cm. from the ear (normal, 150 cm.) Since that time the patient has had several attacks of aural catarrh and pharyngitis, but no suppurative otitis.

Case II.—A mill-owner, fifty-three years of age, was seen in consultation with Dr. W. F. Miller, January 5, 1891. This was on the sixth day of an attack of facial erysipelas, that began on the mucous membrane of the lower lip. Two days previously earache had set in, and the pain was intense. The pharynx was inflamed, and the nasal passages almost occluded. The erysipelas involved the entire side of the face, and had been on the scalp, but had somewhat receded. The drum ruptured spontaneously, and some pus was discharged. The pain continued, and the mastoid became red and tender.

A small perforation could be seen in the membrana flaccida. As the patient was suffering from retention symptoms I made a free paracentesis in the membrana vibrans, which let out considerable thick secretion. The pain still continued, and morphine was given and leeches applied. Cocaine drops were ordered for the ear. The secretion remained thick and creamy for over a week. Antiseptic treatment was advised and used by the attendant throughout the case, and four weeks after the paracentesis I was informed by the physician that the patient had left town for his home in Montana, with the ear apparently well. The attack of erysipelas ended by lysis, with no relapses.

Case III.—A widow, twenty-five years of age, was seen in consultation with Dr. T. H. Hay, April 11, 1890. She was convalescing from a severe attack of facial erysipelas, which had already relapsed once. The disease had arisen at the right nostril, and had spread over the face and neck of the same side. There had been a case of erysipelas in the neighborhood which the patient had visited a few days before her present illness. She acknowledged the habit of "picking" the nose. On examination

[4] Gottstein, J.: Die Krankheiten des Kehlkopfes, Wien, 1888.
[5] Allen, Chas. W.: "Treatment of Erysipelas," Amer. Journ. of the Med. Sciences, July, 1891.

the nasal passages were found swollen and the pharynx reddened. There had been sore-throat for some months; ear-trouble had appeared one week previously to my visit, the drumhead bursting spontaneously, setting free a large quantity of pus, but not giving much relief from the intense pain. The discharge was thick and profuse, and the mastoid was tender. Leeches and antiseptic treatment were used in the treatment of the ear. No erysipelas was seen at this time on the skin, although the temperature was from 100° to 103°, and the pulse rapid and feeble. A few days later the tip of the nose was again red and swollen. The patch gradually extended over the cheek, but at the end of four days had disappeared. The temperature then dropped to the normal. When the patient was seen May 17th the hearing-distance for the affected ear was normal, and the drumhead restored.

It will be noted that the three cases exhibited the ear complication at the beginning, middle, and end, respectively, of the erysipelatous attack. In all, the inflammation was very violent, differing from the ordinary purulent process in severity, and in that the discharge was thick and creamy from the first, maintaining its consistency to the end. The patients were all dangerously ill, and had excessive pain, which was not readily relieved. The secretion of Case I. was examined under the microscope, which revealed an abundance of pus-corpuscles with many epithelial masses. Under a higher power many cocci were visible. In my mind there is no doubt but that the suppurative complication was in each instance a true erysipelatous inflammation at the beginning, modified by its environment, propagated by an extension of the specific disease from the nose and pharynx through the Eustachian tube to the middle ear.

ON THE EVACUATION OF SPINAL ABSCESSES WITHOUT DRAINAGE.[1]

BY G. A. WRIGHT, B.A., M.B. OXON., F.R.C.S.,
SENIOR ASSISTANT SURGEON, ROYAL INFIRMARY, MANCHESTER, ENG.; SURGEON TO THE CHILDREN'S HOSPITAL, PENDLEBURY AND MANCHESTER.

IT would be hard to find a surgical problem more difficult to solve than that of the best method of treating abscess arising from tuberculous disease of the spine. There are surgeons who never open a spinal abscess, and trust to one or another mode of treating the carious spine, in the hope of the abscess becoming quiescent or drying up. Others open abscesses only when they are on the point of bursting; others use aspiration, repeated twice, or more often, if the cavity refills; others open without draining by the old valvular incision; others open and drain, without doing more. Others again open and drain after washing out the cavity more or less thoroughly. Some open an abscess where it approaches the surface; others seek it at the nearest accessible point to the bone lesion. Treves, taking a rational view of the condition, sought to remove the cause of the abscess by reaching the carious focus and removing the dead or hopelessly diseased bone. Barker and others have dealt with the abscess cavity by careful cleansing and removal from it of all caseous and tuberculous material, as far as possible, with an attempt at obliteration of the abscess-cavity by immediate union of its walls. Other methods have also been adopted—hyperdistention of the sac, injections of various kinds, and so on. The very multiplicity of methods shows the inefficiency of any one to meet all cases. The ideal treatment would, of course, be a combination of Treves's and Barker's methods—the removal of the focus of disease to which the abscess is due, together with the removal of the contents and wall of the abscess-cavity. Unfortunately it is only in a very small minority of cases that this is practicable. As a rule, it is quite impossible to reach and clear away the carious focus in the spine. On the other hand, as, with efficient treatment, the bone-disease frequently becomes healed and the caseous material is detached and thrown off into the abscess-cavity, we may hope by thorough removal of the contents of that cavity to obtain a good result in a certain proportion of our cases, and this without leaving behind a possible source of future infection, such as after any of the other methods of treatment.

Barker's method must therefore be considered as the most scientific and practicable method of dealing with these difficult cases. Failure is due either to the fact that the disease in the spine is progressive, or to imperfection in the operation. The whole of the morbid material may have been removed from the abscess-cavity, and yet more may descend the (usually) narrow track leading from the diseased bone into the wider abscess-sac below. In such cases, even if the abscess has been obliterated after the first operation, it will sooner or later refill. The right treatment in such cases, I believe to be, to repeat the operation, just as in the first instance, and I would not hesitate to repeat it a third time, or oftener, if necessary. Therefore, if after the first operation a sinus forms and persists, it should be carefully scraped out again as soon as it is clear that sound healing will not occur; if left, tuberculous infiltration of the walls of the sinus is likely to take place. I have not entered into a detailed description of the operation; it is sufficient to say that a large opening should be made and the walls of the sac carefully scraped away with Volkmann's spoon or some other instrument, and well rubbed out with artificial sponges or similar material. The cavity should then be well washed out with an antiseptic lotion, and iodoform in suspension or solution, in-

[1] Read at the meeting of the American Orthopedic Association held in Washington, September, 1891.

jected. The excess of fluid should be squeezed out, the wound closed and dressed with firm pressure to keep the walls in contact, and, so far as possible, the cavity obliterated. If all goes well, no change of dressing is required for a week or two, and then if the case is successful, the wound is found healed.

Mr. Mayo Robson appears to have had considerable success in the treatment of these cases by repeated aspiration and injection solely of iodoform solution, but this cannot be looked upon as so perfect a method as Mr. Barker's, inasmuch as infectious material is far more likely to be left behind. While I believe that the principle of Barker's operation is the best, an examination of the notes of my cases shows that in most instances it has failed. The failure has been due not apparently to any septic condition, but simply to the fact that, as already pointed out, the whole of the disease has not been removed. My conclusions as to the treatment of spinal abscesses are:

1. The first essential is *rest*, in its surgical sense, to the spine.

2. When efficient rest has been provided, an abscess, unless it is increasing, should be left to itself for a period of not less than a month.

3. If the abscess increases and is evidently going to open spontaneously, or, if there is acute suppuration going on, the abscess should be dealt with by Barker's method, provided thorough asepsis can be assured.

4. An abscess that remains stationary for more than two months, or thereabouts, should be dealt with by Barker's method, provided that throughout the period *rest* to the spine has been secured.

5. Receding abscesses should be left alone.

6. Residual abscesses, if stationary or advancing, should be dealt with by Barker's method, and will nearly certainly be cured.

7. Refilling of an abscess or persistence of a sinus after evacuation should be dealt with by a repetition of the operation so soon as it is evident that repair will not take place, *i. e.*, usually in a month.

8. If there be a doubt about the real maintenance of asepsis, either from want of training on the part of the surgeon or his assistants, nurses, friends, etc., the abscess should either be left alone or dealt with by aspiration and injection of iodoform.

(I may refer to Mr. Barker's paper, *British Medical Journal*, February 7, 1891; to that of Mr. Mayo Robson, *British Medical Journal*, April 25, 1891; and, in the same number, to some cases of my own bearing on this question.)

The University of Moscow has received two hundred thousand roubles (one hundred thousand dollars) from an anonymous donor, for the establishment of a clinic of diseases of the skin and syphilis.

CLINICAL MEMORANDA.

A CASE OF MALFORMATION OF THE RECTUM AND IMPERFORATE ANUS.

BY J. W. SNOWBALL, M.D.,
OF PLAINFIELD, N. J.

THE child, a male, was born Monday, June 13, 1891, by breech presentation, the labor lasting about two hours and a half. At birth the child was apparently robust and perfectly formed, but on the following day the nurse called attention to the fact that there had been no movement of the bowels, and upon making an examination the anus was found to be imperforate. The external sphincter was formed, giving the anus its normal appearance, but protruding through it and attached all the way around to its internal margin was a small pouch of skin; this was clipped off and it was then seen that a very small opening existed into which a probe could be passed for about half an inch. This opening was enlarged a little, and the case was allowed to remain in this condition for two days longer, or until Thursday, in order to see if any pouching would take place. In the meantime the urine was closely watched for meconium, to determine whether there existed any communication between the bladder or urethra and the rectum; none was found, nor was there any abnormal opening visible. No further pouching at the anus took place, and the general condition of the child remained much the same.

Dr. W. J. Swinton was now called in consultation, and it was decided to attempt to reach the rectum and if possible bring it down and attach it to the anus. Accordingly an incision was made through the anus in an upward and backward direction for nearly an inch and a half. Dense tissue was encountered all the way, but no bowel was found. The results of colostomy were then explained to the parents, and they decided against it, preferring that the child should perish rather than go through life with an artificial anus.

On Friday and Saturday the child had several severe convulsions. I gave it small, frequently repeated doses of sodii bromidi, spts. frumenti, and tinct. opii camph. No more convulsions occurred and the only perceptible change in the condition of the child was its gradually increasing weakness, until Wednesday the 24th ult., when the abdomen began to swell, but this subsided in a day or so. On the following Wednesday a well-marked peritonitis again appeared and the abdomen became very much swollen, tense, and discolored. This continued until death. On Saturday fecal vomiting occurred and was repeated at intervals until death. No change in the appearance of the anus occurred and there was no pouching or discoloration at any point that would indicate that nature was endeavoring to find a rent. Death from asthenia and peritonitis occurred July 8th, twenty-three days after birth.

With the assistance of Dr. James Wood, an autopsy was held four hours after death. The rectum was found to end abruptly in a cul-de-sac just behind the bladder and a little less than two inches from the anus, with which it was connected only by dense connective tissue through which there was no opening.

Prior to the birth of the child there had been scarlet

fever in the family, but the mother had suffered with nothing more than a sympathetic sore-throat. The child had a bright scarlet rash on its body at birth, which disappeared on the second day, and was followed by a general and profuse desquamation.

OPERATION FOR HYDROCELE.

BY R. J. CHRISTIE, SR., M.D.,
OF QUINCY, ILL.

THE following method of operating for the radical cure of hydrocele, will, I think, be found to have certain advantages. It is particularly applicable when carbolic acid is used, but other fluids may be used by the same means. I have used carbolic acid only, as that agent is much less painful than others and quite as efficient.

Only two instruments are required—one being an aspirator and the other a hypodermatic syringe. The latter should have a capacity of thirty minims and a needle of largest caliber. After properly cleansing the scrotum, the hypodermatic needle is pushed well into the hydrocele and the wire passed into the needle and beyond the point to prevent choking of the needle and jagging by its point. Keeping the needle securely in the sac, the fluid is then drawn off with the aspirator or trocar. Having withdrawn the aspirator-needle, attach the hypodermatic syringe, filled with pure carbolic acid, to its needle, and inject from ten to thirty drops; clasp the tissues around the needle with the thumb and finger, withdraw the needle quickly, distribute the acid by gentle manipulations into all parts of the sac, envelop the scrotum in borated cotton or gauze, suspend the testicles, and the operation is completed.

If it is thought desirable, in order to prevent pain, cocaine may be injected through the aspirator-canula and allowed to flow out before the acid is injected, but the carbolic acid itself acts very quickly as a local anesthetic.

The acid should not enter the needle before it is ready to be injected, else it might coagulate the albumin and stop up the needle.

The only chance for septic contamination is in the passage of the instruments through the tissues, which can, of course, be avoided by sterilization.

The advantages of this procedure are as follows: In all cases where there is a doubt in diagnosis the needle removes it. It accomplishes the injection without any danger of infiltration. The quantity thrown in is definite to a drop. The method is thoroughly aseptic.

TWO UNUSUAL CASES.

BY JAMES MITCHELL, M.D.,
OF MADISON, W. VA.

A SWALLOWED SILVER HALF-DOLLAR PASSED BY THE BOWEL.

ON the 22d of April I was called in great haste to see E. G., a female, seventeen years old, who a short time previously, while amusing herself by holding a half-dollar in her mouth and at the same time talking and laughing with some friends, had swallowed the coin. I found the family much excited, while the young woman herself was intensely alarmed. She pointed to the place where she thought the erratic half-dollar had found lodgment. The breathing was accelerated, but there was no dyspnea; neither was there pain or soreness at the point designated. Careful manipulation failed to detect anything in the throat. The girl was able to swallow a glass of water without any difficulty.

I informed the family that, beyond all doubt, the coin had already passed into the stomach where it would do little or no harm, and that there was some hope that the coin would be evacuated by the bowel. Three days later the last event transpired.

WORMS IN THE AUDITORY MEATUS.

On the 17th of October, 1891, W. B., a stalwart colored man, between twenty-five and thirty years old, entered my office complaining of pain in his ear, which he ascribed to the presence of a worm. Blood and pus were oozing from the ear, inspection of which disclosed the presence, deeply within the meatus, of a very lively white worm, which I succeeded in removing by means of a grooved director, and the procedure was repeated until I had removed four worms. The worms when removed were about half an inch in length, but when placed on a shingle they stretched out to an inch or more. They appeared none the worse for the rough handling they had received, for they continued in active movement, crawling like the earth-worm, but with much greater celerity. They were perfectly white, except for the head, which was small, black, and hard. I have never before seen any worm like them in the human ear or elsewhere, nor can I find a description corresponding to them in any of my books.

HOSPITAL NOTE.

REMARKABLE CASE OF VOLUNTARY CONTROL OF MUSCLES.

BY JOHN H. BRINTON, M.D.,
PROFESSOR OF THE PRACTICE OF SURGERY AND CLINICAL SURGERY AT THE JEFFERSON MEDICAL COLLEGE.

[*Clinic of the Jefferson Medical College Hospital, Oct. 31, 1891.*]

BEFORE dismissing the class, I wish to bring before you C. E. H., aged thirty-four years, married, Pennsylvanian, an iron-moulder by trade. Since boyhood he has possessed the power of individual contraction of many muscles, and of apparent dislocation, or subluxation, of certain joints. For the last two and a half years he has given public demonstrations of these muscular contractions about six or eight times daily, but has limited the joint-displacements to once a day.

When directed, the man contracted the *platysma myoides*, first on one side and then on both. The "risus sardonicus" was marked, and the elevation of the superficial fascia was demonstrated, so that the pumping effect on the veins coming from the head, as pointed out by Hyrtl, of Vienna, became manifest. The *sterno-cleido-mastoid* muscles were then contracted first on one side and then on both simultaneously, in their clavicular and sternal origins. The bellies of the muscles, and their insertion, were brought into strong relief, and the triangulation of the neck was distinctly shown. The *pectoralis major* and *minor*, and the *latissimus dorsi* were

equally brought out, and the axillary cavity exhibited, with its anterior and posterior limits hard and rigid. The slips of origin of the *serratus magnus* were made to present like the teeth of a saw.

The *deltoid* and *biceps flexor cubiti* were next shown; the long and short heads of the latter were marvellously distinct, and the tendon of insertion, with its aponeurotic slip to the forearm fascia, was made to stand out. When the forearm was fixed, a wonderful contraction or wave of motion could at will be transmitted along the biceps belly from below upward. The heads of the triceps extensor were also well shown. The voluntary action of the *forearm muscles* was equally pronounced. The *palmaris longus* and the *carpal flexors* responded perfectly, and conraction of the spiral fibers of the *supinator longus* and *supinator brevis* produced a remarkable effect. The action of the muscles of the *lower extremity* was in like degree conspicuous, especially that of those inserted into the patella. The heads of the *quadriceps extensor* were relaxed at will, thus permitting free lateral motion of the patella, which could be made to assume a very oblique and approximately vertical position.

A varicose condition of the *internal saphenous vein*, throughout its entire course on the thigh and leg, could be instantly brought about by some voluntary effort, which at first sight seemed inexplicable. Above the knee the vein was greatly increased in size, and below on the leg, it became enlarged, tortuous, and distended with blood, exactly as in an ordinary aggravated case of varicose veins of the leg. The column of blood seemed very large, and communicated a purring thrill when felt. This varicosity did not seem to be the result of the contraction of any of the muscles of the groin. The man said that "the under-skin of the thigh felt tight," and referred the muscular sensation to the outer side of the thigh. On examination, great muscular tension was detected over the outer side of the thigh and hip with external rotation of the trochanter, and fulness anteriorly over the head of the femur, dependent probably upon partial subluxation produced by enforced action of the *glutei* and possibly of the *tensor vaginæ femoris* muscles. As this varicose condition was evidently likely to become a permanent one, a discontinuance of the distending practice was strongly advised.

By fixing the hand, the head of the humerus could seemingly be dislocated backward. An apparent luxation of the head of the femur on the dorsum of the ilium could also be produced by strong muscular effort, the limb being shortened, adducted, inverted, and the sole of the foot carried across the instep of the oppo-ite foot This latter sign was more marked than in the ordinary iliac luxation. It evidently depended upon a synchronous partial inward dislocation of the ankle. Careful measurement showed that the trochanter rose about one inch above Nélaton's line, not nearly so much as it should have risen had the luxation been veritable and complete. By Allis's test, the thigh was lengthened instead of being shortened. It was, therefore, evident that the luxation was partial, and that the femoral head rested on the upper and external portion of the acetabular lip, and was held there by great muscular effort.

In like manner it was manifest that the apparent luxation of the head of the humerus backward was incomplete, and was caused by similar voluntary muscular action. The dislocations of the *patella* were lateral and incomplete, and were nearly vertical. A complicated twist of the knee-joint was produced by manual force, the exact anatomical relations of which it was difficult to determine. At the ankle-joint a partial internal displacement could be developed at will. Imperfect motion could also be established at the junction of the manubrium with the body of the sternum.

The production of the displacements at the larger joints, the man states, is invariably accompanied by a sharp, twitching, nervous feeling, which extends up the spinal column to the base of the brain, and which is often followed by severe headache. In the development and reduction of these displacements he is conscious of the ligamentous and muscular strain, and can feel and hear the sliding of the bones, the sound of which can also be heard and the jerk seen by those around him, as you, gentlemen, can bear witness. The reduction can be readily accomplished, provided he is allowed to concentrate his mind upon his muscles, and is not disturbed by questions or otherwise interfered with. On one occasion, in attempting some abnormal movements at the articulations of the lower jaw, he really did produce a complete bilateral luxation, which he could not replace, which remained unreduced for two hours, and which was then reduced by a surgeon.

This man also possesses the power of slowing, almost to cessation, the radial pulse. This he accomplishes by voluntarily pressing the head of the humerus upon the lower part of the axillary artery and by general muscular compression of the arm-vessels. When this is done upon the right arm, the left radial pulse, as well as the femoral beat, is greatly diminished. The action of the heart is much slowed, and the beats become very feeble and indistinguishable. Auscultation shows the first sound of the heart to be slightly booming and muffled; otherwise the heart is normal.

The man has stated to me that he can at will arrest the flow of urine in full stream, and that during sexual congress he can for the time being hold or prevent, and also instantaneously interrupt the escape of semen, which must, therefore, pass backward into the bladder. If this be so, it evinces a remarkable control over the cut-off muscles of Wilson and Guthrie, and possibly over those of the bulb of the urethra. He has no voluntary control over the cremaster muscles.

The examination of the muscular movements and articular displacements in this case have been made with the coöperation of my colleague, Professor Keen, and that of the circulatory phenomena with the co-operation of Professor Hare.

MEDICAL PROGRESS.

A Case of Pneumothorax and Pneumopericardium.—LUNDIE (*Edinburgh Medical Journal*, September, 1891) reports the case of a clerk, twenty-two years old, who one day while at dinner, in apparently perfect health, was suddenly seized with severe pain in the left scapular region and shortness of breath. When seen, a few days later, the expansion of the left chest was deficient and the percussion resonance was heightened. The usual area of cardiac percussion-dulness was wanting.

The breath-sounds were feebly heard—in some places not heard at all. There was no elevation of temperature and the frequency of the pulse was but slightly accelerated. Under treatment, recovery progressively took place. Five weeks after the first occurrence, pain in the left side of the chest again set in. When the patient assumed the dorsal recumbent posture, the cardiac impulse could not be seen or felt, and the usual area of cardiac percussion-dulness was resonant; but when the patient, was erect, the impulse was felt and there was dulness over the lower portion of the sternum. On palpation a thrill was felt in the precordia. On auscultation, irregular, tumultuous tinkling sounds were heard, more intense with the systole. The explanation of the phenomena is that, in the first attack, pneumothorax resulted. In consequence of pleuro-pericardial adhesions that existed, the heart was, with the lungs, displaced backward. In the second attack, pneumopericardium developed. The only assignable cause for the entrance of air into the pleura and pericardium is rupture of the adherent and delicate membranes as a result of some unusual effort.

Operative Treatment of a Cyst of the Pancreas.—Albert (*Wiener medizin. Presse*, No, 43, 1891) recently presented to the Royal Society of Physicians of Vienna a man upon whom seventeen months previously he had operated for a tumor of the pancreas. Clinically, there was a tumor, as large as the uterus at the end of pregnancy, situated in the epigastrium and sending a process into the pelvis, the percussion-dulness of which posteriorly was indistinguishable from that of the liver and which was taken for an echinococcus of the liver. As, however, the stomach could be detected anteriorly to the tumor, a diagnosis of tumor of the pancreas was made and operation advised. When the abdomen was opened by a median incision and the transverse fascia divided, no translucent membrane was found; so that to enter the free peritoneal cavity, a second incision was made in the right hypogastric region, the tumor reached and punctured. After the cyst was evacuated, it was drawn forward, and a portion that appeared to protrude from the foramen of Winslow was removed. It did not seem advisable to remove the entire tumor, on account of the high mortality (50 per cent.) of such operations. For some time after the operation, a saccharifying and peptonizing fluid was discharged through the wound, progressively diminishing in quantity. The case was the third of tumor of the pancreas operated on by Albert.

Scleroderma.—From clinical observations in three cases and a post-mortem study of one, Dinkler *Deutsches Archiv für klin. Med.*, Bd. xlviii., H. 5 u. 6) maintains that scleroderma is a disease *sui generis*, characterized at the outset by firm swelling and at a late stage by cicatricial-like atrophy of the cutis. The swelling is frequently preceded by vasomotor disturbances. Pigmentation and desquamation may take place, but are not distinctive. Scleroderma may be diffused or circumscribed. The disease process is not restricted to the skin; it may appear in the brain and in striated muscular tissue. The etiology of the disease is obscure; the affection may appear spontaneously or it may follow acute or chronic injuries. It is anatomically characterized by hyperplasia of the connective tissue and by vascular changes. The disease of the vessels involves only individual arterial branches and corresponds to periarteritis, mesarteritis and endarteritis. Clinical observation and anatomical investigation render it probable that the disease is dependent upon an inflammatory process especially involving a varying arterial distribution. The prognosis is dubious. Treatment must be constitutional, conjoined with the application of the constant current and warm baths.

Death from Pyemia as a Result of the Sting of a Fly.—Paltauf (*Wiener klin. Wochenschr.*, No. 35, 1891) has recorded the case of a woman, thirty years old, who was stung on the right eyelid by a fly. On the following day there were considerable swelling, redness and pain in the right temporal region, with fever, and to these were added cerebral symptoms. On the second day manifestations of collapse appeared, with heart-failure; death ensued on the morning of the third day, little more than forty-eight hours after the fly-sting.

At the autopsy, in addition to the conditions observed during life, there were found multiple phlebitic thrombi and abscesses in the texture of the right temporal muscle, thrombi in a radicle of the cavernous sinus and in the sinus itself, an excess of fluid in the pleural cavities, and multiple, softening, hemorrhagic and purulent thrombi in the lungs. There were also parenchymatous swelling of the kidneys and liver and acute enlargement and softening of the spleen. The pus of the phlebitic abscesses in the temporal muscle, of the pulmonary infarcts and incipient abscesses, and the fluid of the spleen contained many cocci, which on culture proved to be principally staphylococci aurei together with staphylococci albi.

Purified Tuberculin.—Koch (*Deutsche medicin. Wochenschr.*, October 22, 1891) has announced the results of investigations conducted in an endeavor to isolate the active principle of tuberculin. By treating the crude product with absolute alcohol, and then with 60 per cent. alcohol, and finally drying, he was able to obtain a light-gray powder representing about one-half of the active principle. From the large proportion of ash to which it gives rise, and from its variability of reaction to numerous tests, the product is thought not to be an absolutely pure one. It is readily soluble in water and feebly soluble in alcohol. Preserved in glycerin, it retains its activity for months From its chemical reactions purified tuberculin is considered to belong to the group of albumins. It differs from the albumoses, which it most closely resembles, and from the toxalbumins, in its resistance to high temperatures. It differs from the peptones in that it is precipitated by iron acetate. It is possible that it may belong to a distinct group of albumins that includes also the products of other pathogenic bacteria. The physiological effects of the purified product, as observed in guinea-pigs and in man, are identical with those of crude tuberculin.

Actinomycosis of the Peritoneum, with Recovery after Operative Treatment.—Kern (*Corresp.-bl. für Schweizer Aerzte*, September 15, 1891) reports the case of a gardener, twenty years old, who had an attack of typhlitis,

which moderated under rest in bed, liquid diet, and the application of ice-bags and cold in other forms; but it was six months before material improvement set in, dull pain in the right iliac fossa, however, persisting. As time wore on, diarrhea developed, a sense of induration in the lower half of the right side of the abdomen became perceptible, and progressive emaciation appeared. Subsequently multiple fistulæ formed in the anterior abdominal wall, giving vent to fetid, yellowish pus, containing numerous grayish-green granules, as large as pin-heads, which, on examination, proved to be actinomyces-masses. Irrigation with saline solutions and with iodoform emulsion proving futile, the various sinuses were laid open, all suspicious surfaces curetted, and the thermo-cautery applied. Ultimately complete recovery ensued. Examination of the contents of several carious teeth that the patient possessed had yielded negative results.

Congenital Muscular Wry-neck.—PETERSON (*Zeitschr. f. Orthopäd. Chirurg.* (i, 1, 1891), from a study of the subject of congenital, muscular wry-neck, has arrived at the conclusion that there is no evidence that wry-neck has ever developed from rupture of a normal flexor or extensor of the head during birth. Clinical experience in the sequelæ of tears of muscles, as well as the negative evidence of experiments in animals, is against such an etiological relationship; while the occurrence of intra-uterine shortening of a flexor or extensor of the head has been demonstrated. Clinical observation and experiments in animals have shown that permanent approximation of the points of origin and insertion of a growing muscle is followed by shortening. The intra-uterine development, the preponderant involvement of the right side, as well as the frequent occurrence of wry-neck in cases of pelvic presentation and of difficult labor, are readily explicable by an abnormal condition of the amnion, and require no further explanation. Stromeyer's dictum of the traumatic origin of wry-neck has not been sustained. The accoucheur cannot be held responsible in any case of congenital wry-neck.

Extirpation of the Gall-bladder, with the Establishment of a Communication between the Duodenum and the Common Choledoch Duct.—In operating upon a woman forty years old, with calcular obstruction of the cystic duct, SPRENGEL (*Deutsche medicin. Wochenschr.*, Sept. 3, *1891*) mistook the cystic duct for the common duct, and the common duct for the intestine. By expression the calculus was forced from the cystic into the common duct, and it was thought that the biliary passages were free. The symptons continuing, however, the abdomen was again opened, and two calculi were found, one in the cystic duct, and the other at the transverse fissure of the liver. On account of the former the gall-bladder was removed, and the cystic duct was ligated; the second calculus was crushed. To overcome the obstruction in the common duct an artificial communication was established with the duodedum. Three months later the patient had recovered, and was free from symptoms.

The Diuretic Action of Fresh Thyroid Juice.—In a case of myxedema, FENWICK (*British Medical Journal*, October 10, 1891), in the course of grafting the thyroid gland of a sheep, split the gland and, before placing it in position, rubbed into the subcutaneous tissue some of the glairy secretion that oozed from the cut surface. On the following day, the temperature of the patient had risen from its habitual subnormal level to the normal, and the quantity of urine had increased from twenty to fifty ounces per day. In a second case of myxedema, thyroid juice was injected hypodermatically, with similar results. In healthy persons no such results were observed.

Fenwick expresses the view that the current theory of the action of the diseased thyroid gland is incorrect and that the condition of myxedema is dependent upon a perversion of the renal function.

Cirsoid Aneurism of the Foot.—At a meeting of the Royal Society of Physicians of Vienna, BILLROTH (*Wiener medizin. Presse*, No. 43, 1891) presented a corrosion preparation made from the amputated left foot of an hysterical woman, fifty years old, who had complained of pain in the member. The foot was edematous. On deep palpation over the malleoli, decided pulsation could be detected, and on auscultation an aneurismal bruit was to be heard. By firm pressure, defects in the fibula were recognized; on removal of the pressure, pulsation became perceptible. A diagnosis of pulsating sarcoma in the bone was made and the foot was amputated. The corrosion preparation showed, however, that both malleoli were occupied by convoluted plexuses of blood-vessels surrounded by masses of round cells. In the course of a short time similar manifestations appeared upon the right foot, so that a revised diagnosis of cirsoid aneurism was made.

Subcutaneous Injections of Cocaine in Trigeminal Neuralgia.—MALHERBE (*Gaz. méd. de Nantes*, No. 11, 1891) has reported two cases of obstinate trigeminal neuralgia that, having resisted the ordinary means of treatment, finally yielded to subcutaneous injections of a third of a grain of cocaine hydrochlorate. The injections were made at the point of the greatest pain, at first twice a week, then, as the intervals between the paroxysms were prolonged, every ten days and more. One of the cases was in a woman, seventy years old, who for nineteen years had suffered with severe neuralgia of the left mental and buccal nerves. The second case was also in a woman, fifty-four years old, who for five years had suffered with neuralgia of the right infra-orbital nerve.

The Dermatoses of Musicians.—STERN (*Münchener medicin. Wochenschr.*, October 20, 1891) has recorded cases of sycosis in violin-players that developed in the left submaxillary region as a result of the mode of supporting the instrument. In a flute-player an eczema of the chin and lips developed from the use of an instrument with a wooden mouthpiece. Under appropriate treatment the condition was remedied, and on the substitution of an ivory mouthpiece did not return. In trumpeters Dr. Stern has observed various abnormalities of the lips as a result of impact against the mouthpiece.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment. When necessary to elucidate the text, illustrations will be provided without cost to the author.

Address the Editor: GEO. M. GOULD, M.D.,
1004 WALNUT STREET,
PHILADELPHIA.

Subscription Price, Including Postage in North America.

PER ANNUM, IN ADVANCE . . . . . $4.00.
SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, NOVEMBER 21, 1891.

THE UNTRUSTWORTHINESS OF THE LAY PRESS IN MEDICAL MATTERS.

UNLESS the writing be a verbatim quotation from a medical journal it is quite impossible for an educated physician to finish the reading of an article on a medical subject in a non-medical journal without a smile either of contempt, of amusement, or of both combined. A strange fatality seems to attend the filtration of medical facts through the lay editorial and reportorial mind. Not long since, the editor of one of the most popular and respectable magazines, with puzzling injudiciousness, allowed a professional humorist the use of his columns to prove that the quintessential nonsense and mummeries of medieval therapeutics had been extinguished solely by the power of so-called homeopathic rationalism and science. By reason of this exquisite illogicality the humor of the sketch to discriminating minds was greatly but unconsciously heightened. In a recent number of one of the best of English magazines, an author and the editor evidently thought that they were firing at the slow-going medical profession a discovery of vast importance as to the resuscitation of asphyxiated persons. What was new in the discovery was not true, and what was true was by no means new. Had we space we could adduce from recent journals of otherwise good reporting ability a score of examples of most egregious and not infrequently amusing misrepresentation. We complain, so far, of no intentional misinformation, but wish only to emphasize the fact that with the best ability and intention the result is ludicrously inaccurate and the mind of the ordinary reader is filled with half-truths and untruths that perpetuate the proverbial and frightfully inaccurate jumble of opinions as to medicine held by the ordinary individual.

If we descend from the better class of carefully edited serials to the preposterous Sunday newspaper and the outrageous advertising sheets supplied Master Demos, we are at once confronted with a farrago of unmedical travesties of medical knowledge quite beyond adequate description and worthy vilification. Here begins an ignorance that is far more than culpable and a misrepresentation that is at once venal and shameless.

Even in many of the best papers the power of the patent-medicine man, the World's Therapeutic Institute, and the advertising agent is supreme. The profitable advertisement closes the editorial mouth or opens it with a promptness that is comparable only to that of a rigid mechanism responding to a pre-ordained stimulus. The most striking exemplification of this has lately occurred. From one boundary of the United States to all the others almost every newspaper of this broad democratic land has been repeating as news and howling as editorial judgment the echoings of a certain hired advertiser's agent of the patent-medicine fraternity, denouncing and abusing the poor druggist who should dare to offer his customer any preparation other than the "patented" cure-all the poor over-advertised dupe of a customer had asked for. The "substitution evil" has been cursed and spat upon with all the wrath of all the money of all the patent-medicine syndicates of all the Americas. What are the facts? A set of sharpers compound some secret mixture, good or bad, of drugs and syrups, and relying upon the gullibility of people, purchase the press with an odd hundred thousand dollars' worth of advertisements, in order to reap millions. The booby dupe calls at the drug-store for the cure-all. The druggist cannot make a cent on the patented and advertised article, so completely has the advertiser got him in his grip. But the druggist knows the ingredients of the mixture, and knows the advertised article is sold at an enormous profit to the advertiser. He is equal to the emergency and mixes

his own unpatented medicine, truthfully guaranteeing it in every way as good as that of the patentee, and with a fair profit to himself he can sell it at half the price of the advertised and patented article. In a commercial sense he is doing perfectly right, and everybody but the owner of the secret article must wish the druggist well in his hard lot in thus fighting fire with fire. But in hounding the druggist as a scoundrel the general press has shown most superbly how its opinions in medical matters are anything but useful to the community. Could a single one of these guardians of public morality be counted on to help tell the world what a disgrace to civilization the entire vile patent-medicine business is?

The query arises as to the possibility of setting this right—of the possibility of so stating medical truths that the common intelligence may be able to understand them, and of the duty and responsibility of medical men in thus moulding and clarifying the lay mind about these things. Other departments of science have their plebificators, their professional popularizers of knowledge, and in every other sphere attractive handbooks and simple expository treatises are continually multiplied, which, without distortion and mystification, put even the most unlettered *au courant* with the latest discoveries and the most abstract of scientific truths. Why is it that that which pertains most vitally to the welfare of each and every person is left untouched and the unprofessional mind allowed to grope in a gloomy twilight of fancy, prejudice, and ignorance? The continuance of this condition of the lay mind is the essential and almost sole reason that quackery, medical superstition, and medical sectarianism are of such prolific growth. Ignorance and misinformation are the manures of these sad weeds.

Among many there are three principal methods whereby the profession may counteract the malicious influences at work:

1. A persistent endeavor on the part of each of us to have modern and scientific physiology made a more prominent part of the teaching in all schools and colleges. Wherever we can, we should try to influence school boards, educators, teachers, and trustees of educational institutions, both primary and higher, to make anatomical, physiological and hygienic courses of study a necessary part of the curricula.

2. Medical men should write for the newspapers, and should compile elementary manuals that may popularize medical knowledge without mutilating and rendering it absurd or erroneous. We are well aware of the fearful danger lurking in this advice: the license thereby given the schemer to advertise his professional ability and service—a danger that in the present state of professional greed and public indiscrimination cannot be too sharply emphasized and prophesied. But it is not an inobviable danger, and its checks and preventions will, with growing intelligence and morality, be speedily found.

3. The noble and marvellously effective new method of general education, known as the University Extension system, should be seized upon and made use of by the medical profession to extend in the minds of all a correct knowledge of the body and its diseases. The instrument seems as if made to our hand. Professors in medical colleges, teachers of physiology, hygienists, even the humblest practitioners of medicine, have inexhaustible stores of correct observation and knowledge for which humanity is humbly waiting and asking, and which to it would be of inestimable value.

KOCH'S FURTHER STUDIES UPON "TUBERCULIN."

NOTWITHSTANDING the more or less adverse turn taken by the wave of public and professional sentiment concerning the experiments of KOCH upon the treatment of tuberculosis, he properly continues his work in this line, apparently oblivious of all criticism. The latest of his contributions[1] upon the nature of tuberculin, and the method for purifying it, serve to shed considerable light upon the subject.

In this publication KOCH states that tuberculin is an extract prepared from the tubercle bacillus itself.

One of the drawbacks in the preparation of tuberculin, says KOCH, has been the difficulty in obtaining a sufficient amount of material upon which to work. The method of growing the bacilli on solid media until they accumulate in amount sufficient for the extraction of their active principle required so much time that it became necessary to employ other means. KOCH finds that the bacilli can be obtained in much larger quantities by cultivating them in ordinary nutrient veal broth to which from 4 to 5 per cent. of glycerin has been added. The cultivation is to be conducted at a temperature of 38° C., and in vessels that permit of a large surface-area of fluid. When grown in this way the organisms develop very quickly in the form

[1] Deutsche med. Woch., No. 43, Oct. 22, 1891.

of pellicles that float upon the surface of the fluid, and in from six to eight weeks the culture may be said to be "ripe," *i. e.*, ready for the further steps in the process of extracting tuberculin from it. When ripe the cultures grown in this way are to be evaporated over the water-bath at a temperature of 100° C., until they are about one-tenth of their original volume. They are then filtered under pressure through filters of unglazed porcelain or silicon. The filtrate represents crude tuberculin, the form in which it has been employed since its introduction.

The advantage that this method possesses over the original plan for obtaining tuberculin is that from the same number of organisms a much larger amount of active principle can be obtained.

In the original method the bacilli were grown upon the surface of a solid medium, from which they were scraped and extracted in glycerin. In the present method of cultivation in a fluid medium the extraction goes on all the time that the organisms are growing, so that the fluid in which they are developing contains tuberculin in comparatively large quantities.

After extraction by this means the bacilli are robbed almost entirely of their active poisonous principle, the poison having been dissolved in the fluid.

The latest contribution of KOCH presents also an account of experiments made with a view of obtaining tuberculin in a pure state, for the purpose of becoming more intimately acquainted with its true nature. The impure, crude extract was subjected to a number of methods of chemical analysis before a plan was found by means of which it could be freed from coloring and extractive matters and salts, and the active agent alone obtained. Without going into the details of the various methods, it will suffice to state that by subjecting the impure extract to the action of 60 per cent. alcohol, a pure white flocculent precipitate was obtained that, when dissolved in glycerin, presented all the characteristics of the crude extract, but in a more concentrated degree.

Pure tuberculin thus obtained is in its action upon man about forty times as energetic as crude tuberculin, and for guinea-pigs about fifty times as powerful.

The action of purified tuberculin was tested by KOCH upon four of his colleagues, and in all the reactions were in general analogous to those following the use of the crude extract under the same conditions.

An interesting observation in the course of these experiments was a rise in temperature corresponding with the increase in dose. For example:

By subcutaneous injection—

2 mg.	caused a rise in temperature to	38.2° C.
3 "	"	38.7°
4 "	"	39.0°
5 "	"	39.2°

In all of these cases the condition of the individual operated upon returned to normal within about twenty-four hours after the injection.

The result of closer study of the constitution of tuberculin led to the conclusion that it belongs to the class of albumins, though it differs in its behavior with different reagents from both toxalbumins or albumoses and peptones.

According to elementary analysis pure tuberculin has the following composition (PROSKAUER):

	First analysis.	Second analysis.
Carbon . .	48.13 per cent.	47.67 per cent.
Hydrogen . .	7.06 "	7.18 "
Nitrogen . .	14.46 "	14.73 "
Sulphur . .	1.17 "	1.14 "

THE NECESSITY FOR AN ADEQUATE SYSTEM OF CATTLE-INSPECTION.

THROUGH the efforts of the Director of Public Safety and of the Board of Health of the city of Philadelphia, twenty-one dealers in cattle, butchers, and venders of meat have been arraigned and held to answer at court for selling or exposing for sale diseased cattle or unwholesome meat. The diseases from which the cattle suffered were actinomycosis and tuberculosis. The meat condemned as unwholesome was obtained from calves slaughtered when only a few days old.

Actinomycosis, as defined by ZIEGLER, is a progressive inflammatory affection, set up by a certain fungus—the actinomyces—attended with the formation of granulations and fibrous tissue, and with suppuration, attacking human beings, cattle, and swine, and communicable by inoculation. It was first described in the form in which it appears in cattle, in 1877, by BOLLINGER, and in the same year by ISRAEL as it appears in man. Since then the subject has received considerable attention at the hands of numerous writers.

The fungus enters the body through abrasions of

the mucous membrane of the mouth and pharynx, the respiratory tract and the digestive tract. In cattle the disease locates itself primarily in the jaw, and most frequently in the lower jaw.

It presents itself as a tumor resembling a sarcoma, and, from the swelling it produces, is known among cattle-dealers as "lump-jaw." Both ISRAEL and PONFICK have transmitted the infection to lower animals by inoculation from man, but no direct relationship between the disease as occurring in the lower animals and as met with in man has as yet been clearly established. While it is probable that man and the lower animals become infected from some common source, it is possible for the former to be infected by the latter. Cattle suffering from actinomycosis should unquestionably be condemned, and their carcasses destroyed. The fact that a number of cases of actinomycosis have been detected as the result of a limited search indicates that the disease is by no means uncommon.

In the course of the investigation it was further discovered that large quantities of immature veal are constantly being placed on the market. Veal only a few days old is generally watery and flabby, and is difficult of digestion. It is liable to occasion gastric irritation, and on this account should be considered unwholesome as food.

The investigation demonstrates the utter helplessness of the people without a system of vigilant inspection, and the necessity for the institution of means to afford protection against practices dangerous to the public health.

SOCIETY PROCEEDINGS.

PHILADELPHIA ACADEMY OF SURGERY.

Regular Meeting, October 5, 1891.

DR. WILLIAM HUNT, PRESIDENT, IN THE CHAIR.

DR. THOMAS G. MORTON read a paper, entitled "Gunshot Wound of the Thigh; Ball Found in and Removed from the Neck of the Femur; Recovery."

James T., twenty-three years old, was shot with a revolver, the ball entering the left thigh below the groin; two unsuccessful attempts were made to find the ball. Four days later, when admitted to the Pennsylvania Hospital, the patient was able to bear weight upon the injured limb, and motion in the joint was free, showing that there was no solution of the continuity of the bone. The bullet-wound, which was two inches to the inner side of the great trochanter, was inflamed and a considerable amount of fetid pus exuded from the opening. The temperature was 101°. A probe passed in deeply at a right angle to the femur came in contact with bone.

A five-inch incision led to a deep pus-collection. The track of the bullet being opened, the neck of the femur, into which the ball had penetrated, was exposed; but there was no fracture in continuity. With chisel and gouge the track in the neck of the femur was epened to the extent of an inch or more, and the ball was found so firmly imbedded that it was with difficulty displaced and extracted. The excavated track in the bone, as well as the wound of the soft parts, was curetted and cleansed, and a rubber drain inserted.

Convalescence was uneventful, although the wound was slow in closing. The ball was conical and weighed 136 grains. (Patient exhibited.)

From an examination of the histories of cases of gunshot wounds during the Crimean war, the war of the Rebellion, and elsewhere, Dr. Morton had been unable to find any similar recorded case. Hennen, in his *Principles of Military Surgery*, London, 1829, reports, page 158, as follows: "I have seen balls lodged in almost every part of the trochanters, neck, and head of the bone, and yet the most accurate examination during life did not lead to a discovery of the situation."

DR. MORTON read a second paper, entitled "Chronic or Relapsing Appendicitis: Removal of the Appendix in an Interval between Attacks."

Jacob K., twenty-nine years old, eight months previously had an attack of severe abdominal pain lasting several days—the pain being principally in the right iliac region, with the usual symptoms indicating appendicitis. Four months later he had another attack, for which he was admitted into the Pennsylvania Hospital; in a short time was discharged, apparently quite well. A few weeks subsequently he had another attack of pain, but the symptoms were not so severe as to confine him to the house.

About a month previously he first noticed a small lump in the appendix region, on account of which he was, a few days later, admitted to the medical ward of the Pennsylvania Hospital. Temperature, pulse, and respiration were normal; there was no pain at the site of the tumor, which was apparently as large as a pigeon's egg; it was immovable, hard, and oval in shape. The appendix was judged to be enlarged and in a chronic inflamed condition, and as it was liable to become perforated at any time, on account of its retained contents, its removal was advised.

The usual operation was performed, the only difficulty experienced being hemorrhage from division of the epigastric artery. There were no evidences of recent inflammation; the appendix was enormously enlarged, dark-red in color, and so firmly bound to the cecum by old lymph-adhesions that great difficulty was experienced in detaching it from the cecum sufficiently to place a ligature beyond a large, foreign body that it contained. A glass drain was introduced, and the usual dressings were applied.

On examination, the excised appendix was found to have exceedingly thick walls; its mucous membrane was in folds and evidently ulcerated; it contained a large oval concretion resembling an ordinary uric-acid calculus.

The concretion measured an inch in length, and an

inch and a half in circumference; its distal extremity was smooth and rounded, and moulded to the shape of the distended organ; the other end was rough from irregular deposit.

DR. MORTON also read a report of a case of "Perforative Appendicitis; Removal of the Organ; Recovery."

Joseph T., twelve years old, was admitted into the medical ward of the Pennsylvania Hospital, suffering from acute appendicitis, with threatening, if not actual, perforation.

Six days previously he had freely eaten of fruits, and had considerable pain; four days later, after lifting a heavy can of water, he "felt something give way inside, and had a sharp pain." After this the symptoms became progressively worse.

On admission, he had marked local peritonitis and general abdominal pain. In the subsequent six days the symptoms in no wise improved; although there was no tumor or hardness, and the appendix region was not tympanitic, yet the local pain, the sweats, and the slight chilliness indicated pus-formation, and the appendix as the source of the trouble.

A lateral abdominal incision was made; on reaching the cecum the appendix was found glued to it; pus was not discovered until the appendix was separated, when an immense abscess was found, into which the sloughing appendix had emptied its contents; the cause of the ulceration was a large, oval, fecal concretion firmly held in the gangrenous extremity of the appendix. The abscess contained several ounces of fetid pus, and had dissected its way backward to the iliac bone. The appendix was ligated close to the cecum and removed; two drains were introduced. Convalescence occurred without interruption.

DR. T. S. K. MORTON presented another appendix, removed a few days previously, that contained a large concretion, the exact nature of which had not yet been determined. He added that so much has been said about cherry-stones, orange-seeds, and similar bodies forming the nuclei of concretions found in the appendix, that in every case it should be clearly demonstrated that the formation is either a true foreign body or else a fecal concretion.

The appendix demonstrated was removed from a man who had had relapsing attacks during a period of six years, completely undermining his health. He presented the manifestations of acute septicemia, with all the signs of violent appendix trouble. The operation was promptly performed. The appendix was found gangrenous, and the foreign body was discovered. The appendix was removed, and the abscess-cavity washed out and packed with gauze. In the subsequent ten days there was no symptom of any trouble; the man remained perfectly comfortable.

Among the curious bodies that have been found in cases of appendicitis, Dr. Morton mentioned a lumbricoid worm, which was found in a perityphlitic abscess without apparent perforation of the appendix or cecum. It must have escaped from the appendix at some time, the perforation afterward closing.

DR. T. G. MORTON added that in a recent case of perforative appendicitis, a globule of solder, supposed to have been taken with some canned tomatoes, and which had evidently caused the perforation, was found in the abscess-cavity.

DR. JOHN B. ROBERTS stated that Dr. Owens, of Chicago, had related to him a case in which a gelatin capsule was found in the appendix.

DR. O. H. ALLIS made some extemporaneous remarks, in which he endeavored to illustrate a point in the management of cases of supra-pubic operation. In such cases soiling of the clothing by the discharges is sometimes exceedingly annoying! Dr. Allis reported the history of a case in which a year previously he had cut for stone. He performed the lateral operation, and found a soft stone of considerable size. The opening closed immediately, so that it was necessary to draw off the water three hours after the operation; no water ever passed through the wound. The patient remained remarkably free from trouble for about six months; then he began to suffer with irritation of the bladder as before, and he again suspected the presence of stone. The searcher failed to detect a calculus, the examination occasioning a good deal of pain. Dr. Allis then determined to perform the supra-pubic operation; this was done about a year after the first operation. Some small pieces of stone were found in the bladder behind a large prostate. These were removed, and the patient did well after the operation, but a strong odor of urine emanated from the clothing of the patient. After shaving the hair about the opening, Dr. Allis washed the skin with chloroform, then smeared a small amount of liquid-rubber cement over the skin around the opening, and finally stretched a piece of rubber dam over this. The rubber was kept in close contact with the skin for a few minutes, when it adhered perfectly and remained adherent for two or three days. The edges of the dam were then folded up over a piece of absorbent cotton, and in this way the man was kept perfectly free from soiling. In this case it was desired to have the opening remain; the bladder was washed out, the patient assuming a position on the hands and knees, so that the enlarged prostate would not interfere with the discharge of fluid. In this way, during the first month a number of portions of stone, some of considerable size, were washed out. The man has since gotten out some pieces himself. This same application might be of service in cases of breast-surgery in which the patients are much annoyed by the soiling of the clothing.

DR. ALLIS made some further remarks on "Digital Removal of the Entire Prostate." He related a case of enlargement of the prostate in which he performed a supra-pubic operation, removing the entire gland. The patient recovered from the operation, and died about six weeks later from some pulmonary or cardiac complication. After making the supra-pubic opening, Dr. Allis cut through the mucous membrane over the prostate with his finger-nail, and then carried his finger down between the gland and the mucous membrane, dissecting this out in two portions. The masses removed were exceedingly large, and there was very little hemorrhage. The specimen revealed no remains of the prostate gland. The physician who had attended the patient had used the catheter, which would sometimes pass readily into the bladder, and sometimes not. On passing his finger down to the prostate, Dr. Allis found what appeared to be an opening through which a catheter passed, enter-

ing a canal at the base of the gland and emerging at its posterior portion. The catheter could be felt by passing the finger in the opening in the upper part of the gland. The structure of the gland was densely fibrous, and to a certain extent it was lobulated.

Dr. Allis further related that he had performed four supra-pubic operations in each of which there was a certain amount of gangrenous condition about the opening, which subsequently granulated satisfactorily. In every instance the wound was packed from the bottom, with capillary drainage from the first.

DR. T. G. MORTON stated that he had seen cellular sloughs after supra-pubic operations, but not the condition referred to by Dr. Allis.

DR. W. W. KEEN stated that the method described was a very ingenious and a very useful one, and should be widely known. It is by far the best method that he knew of for the control of the annoyance from discharges. It, however, has a wider application than simply in supra-pubic operations. It can be used in any operation in which there is discharge of fluid.

DR. W. JOSEPH HEARN reported a case of hytadid cyst in a man, forty-two years old, a shoemaker, a native of Hungary, who had been in the United States a year. Five months before presenting himself the man had observed a nodule, about as large as a marble, in the right buttock. The mass was painful on pressure and seemed to elude the grasp. It grew with considerable rapidity. On examination a large swelling about as large as three oranges was found on the left lateral aspect of the buttock; on palpation an indistinct crepitus was elicited; there was a sensation as of fluid beneath the deep fascia. The site of the greatest fluctuation changed from time to time in the course of the examination. The skin was not edematous or discolored. The man felt a sense of tension over the femur, great pain on motion, and tenderness on pressure. He gave a history of digestive troubles, was sallow, persistently constipated, and had a coated tongue. Under the belief that there was an abscess the man was etherized, and an incision was made in the buttock. Beneath the gluteal muscles a cyst was opened and a large quantity of serum, together with detritus and daughter-cysts, evacuated. The original incision was enlarged, the cavity curetted, washed out with a solution of corrosive sublimate, and drainage-tubes inserted. For two weeks the wound was irrigated daily with a solution of corrosive sublimate, considerable masses of the cyst-wall being discharged at each washing. Three weeks after the operation there were no evidences of disease remaining.

This case of hydatid cyst of the buttock presents many elements of interest. In the first place a mistake in diagnosis seems to have been anticipated by so distinguished a man as Sir Thomas Watson, who states that the diagnosis is usually made by operating on an abscess and finding an hydatid cyst. In the second place a curative result was obtained by simple incision and antiseptic irrigation, a proof that it is not necessary to remove the cyst-wall.

The next point of interest is the possible source of the disease. It is universally recognized that hydatids are the product of the ova of the tenia echinococcus, the dog usually being the host of the adult worm. The ova find their way with the food or drinking-water into the stomach of man, where they lose their covering and are set free to pursue their wanderings until they find a place of permanent abode.

The patient in question did not keep a dog nor was he accustomed to eating pork or raw beef; but he was exceedingly fond of salad, eating it in large quantities, without taking the trouble to wash it. Bartholow some years ago observed that lettuce is liable to become contaminated with the excrement of the dog, and thus capable of giving rise to hydatid disease. Hydatid cysts are common in Iceland, but rare in the United States.

DR. HEARN also reported a case of "Nephro-lithotomy." The patient, a male, twenty-nine years old, had an attack of "gravel" at ten years of age, but had no further trouble until two years before he came under observation, when he had a severe attack of pain in the region of the right kidney—so severe as to confine him to bed and require the hypodermatic employment of morphine. Following this, he had four or five severe attacks, passing some blood with the urine in each attack. The pain would come and go very suddenly. There was intense pain on pressure both in front and behind the kidney. The man was unable to work, and an exploratory incision was made one inch below the rib, the capsule of the kidney being opened with a knife. On opening the kidney with the finger and enlarging the opening with the knife, a stone was distinctly felt. The stone was so adherent that it was almost impossible to remove it. During the operation the patient lost a large amount of blood. Had it been anticipated that the stone was so firmly lodged, special provision could have been made and the operation need not have been so prolonged. The hemorrhage was so severe that it was thought it would be necessary to remove the kidney. The shock following the operation was most profound; but, as is peculiar in these cases, however profound the shock, it is remarkable how quickly the patient recovers. The man recovered nicely, and in four weeks left the hospital perfectly cured. As soon as the stone was removed the wound was packed with iodoform gauze, and the bleeding at once ceased. After the operation the man passed bloody urine—an evidence that the ureter was patulous. The stone weighed 140 grains.

DR. HEARN reported yet two cases of vesical calculus. One patient, L. B., fifty years old, for eight or ten years had been complaining of aggravated cystitis. Examination disclosed the presence of a stone imbedded in the folds of the mucous membrane. Because the stone was so large the supra-pubic operation was performed. It was not possible to distend the bladder; it would not hold an ounce of water. The stone was apparently adherent to the bladder, and was dislodged with difficulty. The incision was one and a half inches in length. The man did well. There was no sloughing at all, and he went home in two months. Dr. Hearn stated that, if he again should find it necessary to make so large an opening in the bladder, he would suture it, with the exception of an opening large enough to admit a catheter. The procedure would promote recovery. The stone weighed 970 grains.

The second patient was a colored man, sixty-eight years old, who had for four years complained of pain in the supra-pubic region. With this there were frequent

micturition and the usual symptoms of stone in the bladder. When the sound was passed, it seemed as though there was one large stone. A short supra-pubic incision was made, and a small stone removed. It became evident that there were several stones present. In all, five were removed. Their combined weight was 243 grains. The man left the hospital perfectly well ten days after the operation, a demonstration of the advantage of a small incision into the bladder. Dr. Hearn stated that he had been opposed to the supra-pubic method, but he was much gratified at his experience with it. He considered the operation easy of performance.

In the discussion, DR. JOHN B. DEAVER stated that in a case operated upon by him a persistent fistula followed nephro-lithotomy, so that it became necessary to perform lumbar nephrectomy. Both operations were successful—complete recovery ensuing. The question that arose was whether the fistula communicated with the kidney or with the ureter. At the second operation the kidney was found intact, the site of the incision having granulated and the contour of the organ having been restored. The fistula communicated with the ureter immediately below the pelvis. The ureter was probably injured during the primary operation. Dr. Deaver added that he had performed nephro-lithotomy in two other cases, both of which recovered without any trouble. He did not agree with Dr. Hearn with reference to shock. In neither case was there any considerable shock. Not much blood was lost, which would have an important bearing upon the degree of shock.

Dr. Deaver thought that Dr. Hearn's method of proceeding in extracting the stone was much better than that which he had adopted, and that which is generally adopted—namely, tearing into the kidney with the finger or grooved director. It is probable that if, in the case especially referred to, a free incision had been made and the stone removed, there would have been less likelihood of a fistula following.

Dr. Deaver related that a short time previously he had operated upon a man, seventy-five years old, who had a piece of catheter in his bladder. The man had for some years been in the habit of passing a rubber catheter, and, the instrument becoming brittle, a piece had broken off in the bladder. The catheter was removed through a supra-pubic opening; this was followed by a good deal of sloughing, which, in an old man in whom the vitality of the tissues is low, may readily occur.

Another question that arises in these cases of long-standing obstruction, with damming of the urine back upon the kidneys, is whether ether or chloroform is the safer anesthetic. Dr. Deaver believes that, under such circumstances, chloroform is the safer. He had recently operated on a man, seventy years of age, who was daily passing but nine ounces of urine, which contained an abundance of granular casts. In this case he administered chloroform, and no bad symptoms followed. The patient is now passing twenty ounces of urine daily. Dr. Deaver stated that, in his experience with supra-pubic cystotomy for drainage in case of large prostates in men advanced in life, those who die die from a slow form of uremia. That ether may cause congestion of the kidneys was clearly demonstrated a short time before in a case of radical cure for hernia in a young man in whom the urine was perfectly normal. For some hours after the operation the man passed bloody urine and presented the symptoms of congestion of the kidney. If the normal kidney will thus suffer from the effects of ether, the abnormal kidney will probably suffer still more.

The PRESIDENT stated that a number of years ago he had written a short paper entitled "Are the Kidneys Active Eliminators of Ether?" Since that time he has on several occasions had the opportunity of applying a flame to the urine passed by patients undergoing etherization, with the production of a flash of burning ether. That ether thus passes off by the kidneys is a great element of safety in these cases. When there are evidences of renal disease, it may perhaps be safer to give chloroform.

Whether the kidneys eliminate chloroform also Dr. HUNT did not know, but the quantity at best must be very small. The case that first attracted his attention to the subject was a patient brought into the Pennsylvania Hospital with a recent accident-wound necessitating amputation of the arm. Ether was administered, but the pulse almost stopped; the etherization was discontinued, and the operation was postponed. In the afternoon the etherization was resumed, but the same effects occurred. Then the operation was performed without etherization. The patient presented the ordinary symptoms of what is called surgical fever. The urine was albuminous. The man died, and at the autopsy the kidneys were found absolutely disorganized by old disease. From this association Dr. Hunt was led to believe that probably the kidneys serve to eliminate the excess of ether and thus save patients from the injurious effects of the anesthetic.

DR. J. EWING MEARS stated that another point in connection with the administration of ether to elderly persons as well as to children that should be considered is the tendency of ether to induce irritation of the bronchial mucous membrane.

DR. L. W. STEINBACH stated that in his experience renal calculi are usually branched in outline, conforming to that of the calices of the kidney, and thus occasioning great difficulties in removal. Some three years ago, in a case upon which he operated by abdominal section, he found the difficulties in the removal of the stone insurmountable and was compelled to remove the entire kidney. There were several stones, and most of them were branched. He did not remember ever seeing a round stone come from the kidney.

In concluding, DR. JOSEPH HEARN added that he had seen two cases of exploratory incision into the kidney, without great loss of blood, in which the shock was profound, although the patient rapidly rallied.

It has long been recognized that ether is not safe when the kidneys are in such a condition that the anesthetic is not rapidly eliminated. In many cases of death occurring within twenty hours after operation ether has probably been the cause of the fatal result. Dr. Hearn expressed a preference for chloroform, and stated that he administered it often in private practice. It can be given safely, and is to be preferred whenever the kidneys are not in good condition. It is remarkable that more deaths do not occur in urgent cases in which there has not been time to examine the urine.

CORRESPONDENCE.

ROME.

Fourth Italian Congress of Internal Medicine.

THE fourth annual meeting of the Italian Society of Internal Medicine was opened in the "Aula Magna" of the University on October 19th, and continued four days. Some two hundred physicians were present, and although the attendance was smaller than was expected, it made up in quality what it lacked in quantity, for the ablest clinicians and physicians in Italy took part in the Congress.

The number of papers read was so large that it would take too much space to mention all; hence I shall only speak of the reports handed in and read by the members appointed last year.

The proceedings were opened by an eloquent and effective address by the President, Professor Baccelli, which was followed by the reports of Professors Rossoni and Forlanini on the "Pathology and Treatment of the Diseases of the Stomach." Professor Rossoni's report may be summed up as follows:

1st. The modern studies as to the quantitative variations of free HCl in the gastric juice in the various diseases of the stomach have not given decisive results in aiding the diagnosis of the diseases of the stomach.

2d. The conclusions reached by Hayem and Winter in their studies on gastric chemistry are premature. The creation of various "chemical" types of dyspepsia cannot have the importance that some have ascribed to it.

3d. The tendency manifested by the modern French authors to regard the various disturbances of gastric chemistry as morbid entities adds complications to practical medicine.

4th. Despite the progress in modern chemical and functional analysis of the stomach that has been made, the problem of the nature of dyspepsia has not yet been solved.

5th. It has not yet been satisfactorily demonstrated whether dyspeptic phenomena are dependent on chronic gastric catarrh or on gastric neuroses.

6th. The prevalent fashion of determining the chemical type of the dyspepsia leads to neglect of the study of the primary cause to which the dyspepsia is due.

7th. The classifications of gastric neuroses as found in modern works on the diseases of the stomach are useless.

8th. The gastric neuroses had better be described in treatises on diseases of the nervous system.

9th. Bouchard's doctrine of dilatation of the stomach is not clear, and neglects important researches as to the causation of gastric dilatation.

10th. The greatest advance in the treatment of the diseases of the stomach that has been made since the adoption of gastric "lavage" has been the surgical treatment of such grave organic diseases as carcinoma, round ulcers, stenosis of the orifices, especially of the pylorus, and gastric perforation. The results thus far obtained are extremely encouraging.

11th. The intervention of surgical skill in the treatment of organic lesions of the stomach imposes all the more strongly on the physician the duty (1) to make an early and accurate diagnosis; (2) to acquire himself skill enough to perform the various operations required.

12th. The new method of Marino and Sutto for the determination of free and combined HCl in the gastric juice is an excellent substitute for the method of Hayem and Winter as regards simplicity, exactness, and the time necessary to make an accurate analysis.

Professor Forlanini, who followed Rossoni, spoke at length of the chemistry and chemical analysis of the stomach and its contents, with its variations in the different forms of disease.

A prolonged and lively discussion followed these papers.

On the second day the proceedings were opened by the reports of Professors Albertoni and Silvia on "Auto-intoxications." Professor Albertoni's paper was too long to be done justice by a brief *rèsumè*, but Professor Silvia's paper, while not so comprehensive, presents the substance of the subject in such a way as to allow of the following conclusions being drawn:

1st. The healthy organism, like the diseased one, is a continuous manufacturer of poisons, as is demonstrated by the toxic nature of human excretions.

2d. The human organism does not suffer from the presence of these poisons while the eliminative organs perform their functions in a physiological manner, or else when a sufficient quantity of oxygen is present to transform the toxic substances into innocuous products.

3d. Auto-intoxication causes those morbid phenomena due to poisons produced by the organism itself, as a result of its functional activity.

4th. The causes of auto-intoxication may be deficiency or excess of function.

5th. Among the principal conditions due to auto-intoxication are those produced by alterations in the functions of the gastro-intestinal tract—hence many nervous disturbances associated with certain forms of dyspepsia, certain gastric fevers, cases of tetanus and of cramps sometimes accompanying dilatation of the stomach.

6th. Asthma, cases of transient epileptiform paralysis, and cases of neuritis may also be developed by auto-intoxication.

7th. Neurasthenia may sometimes, but not always, be attributed to it.

8th. Diabetic, carcinomatous, and gastric coma are also due to auto-intoxication. In gastric coma the poison is generated in the gastro-intestinal canal, while in diabetic and carcinomatous coma, as in pernicious anemia, it is probably generated in the intimate structure of the tissues.

9th. None of the bodies studied until now can properly be said exclusively to give rise to auto-intoxication: neither acetone nor acetacetic acid; the theory of acid-poisoning in diabetic coma cannot be accepted.

10th. Among the substances that may cause auto-intoxication are peptoxine, organic bases (ptomaïnes and leucomaïnes); products of the aromatic series, such as indol, phenol, aromatic acids, etc.; lactic acid, ammonia, sulphuretted hydrogen, acetone, etc.

11th. Fatigue, excessive mental work, insolation, and starvation cause auto-intoxication by the exaggerated and abnormal formation of some of the products named,

which cannot be rapidly enough eliminated or transformed.

12th. The diagnosis of auto-intoxication depends principally upon the demonstration of the presence in the urine, feces, sweat, and in the tissues, of substances recognized as toxic.. From this point of view we have acquired positive and important means of diagnosis by testing the urine for sulphuric acid, phenol, indican, acetone, ammonia, diamine, the alkaloids, and peptones.

13th. The treatment of the phenomena of auto-intoxication, in addition to prophylaxis, calls for two things: 1st, the transformation of noxious into harmless products; 2d, the elimination and neutralization of these noxious products.

14th. The first is accomplished by the inhalation of oxygen or compressed air; the second, as the case may be, by emetics, purgatives, diaphoretics, massage, or disinfection of the gastro-intestinal canal. In some cases alkaline remedies are found useful.

The discussion that followed the reading of these papers, in which the foremost Italian clinicians took part, was of extreme interest, but would make this report entirely too long. Those interested in the papers and discussion in full can obtain the *Transactions*, which will be issued in about two months.

In the afternoon session of the second day some twenty short communications were presented. On the third day the reports of Professors Patella and Mya on "Jaundice" were read. Professor Patella proposed the following conclusions:

1st. Neither the "hemafecal icterus" of Gubler, the "urobilin icterus" of Gerhardt, nor the "bilirubin icterus" of Tessier can be sustained.

2d. Hematogenous icterus does not exist.

3d. Nearly all the forms of jaundice seen clinically come under the hepatogenous form by resorption.

4th. The mechanism of the production of some forms of icterus is very obscure—that is, the reasons *why* and *where* this biliary resorption takes place.

5th. The physio-pathological conception of so-called catarrhal icterus, as maintained in the past, is no longer sufficient to explain the actual mechanism of its production.

6th. The actual state of our knowledge of the bacteria of the intestinal canal and biliary passages does not authorize us to accept without reserve the infective origin of catarrhal icterus.

7th. Chauffard's idea of its toxic origin—modified in accordance with the results of biologic chemistry and experimental studies on icterus—must be taken into serious consideration in catarrhal icterus, and especially in certain cases of infective jaundice.

8th. Catarrhal icterus can be considered the first link of a chain which, starting from it, reaches to grave and lethal icterus. A plural etiology—a true multiplicity of pathogenic possibilities—must nowadays be given to infective jaundice.

9th. The "morbus Weil," though belonging to this group on account of its clinical aspects, even in the absence of bacteriological or pathological demonstrations, merits, however, a special place, as etiologically specific. Is it bacteric or toxic?

10th. Our present knowledge of biliary infection is incomplete and imperfect.

A large number of papers were read during the afternoon session, with some heated discussions.

On the fourth day a few papers were read, and the President, Professor Baccelli, delivered an able address, in which he pointed out the growing importance and influence of these meetings, and closed by inviting all the members to accompany him on the following day on a visit to the "Policlinico," which is now being built.

A special meeting for the election of officers was held, at which the existing incumbents were all reëlected.

The General Council announced the following subjects to be reported upon at the next meeting, to be held in October, 1892: "Rheumatism," "Cerebral Localization," and "Aëro-therapeutics."

A PLEA FOR HIGHER MEDICAL EDUCATION.

To the Editor of The Medical News,

Sir: The following memorandum was sent with a patient by her attending physician to the resident physician of —— Hospital. I enclose the original for your instruction and delight.

Very truly yours, M. G. H.

NEWS ITEMS.

Dr. John H. Packard, of Philadelphia, has entirely recovered from a recent attack of severe illness, and is enabled to resume the duties of his practice.

Books and Pamphlets Received.

Four Operations for Appendicitis: Three Recoveries; One Death from a Very Small Concealed Abscess. By W. W. Keen, M.D.. Reprint, 1891.

The Climate of Southern California in Relation to Disease. By William A. Edwards, M.D. Reprint, 1891.

A New Method of Tenotomy. By W. W. Keen, M. D. Reprint, 1891.

A Further Communication on a New Method of Compressing the Subclavian Artery. By W. W. Keen, M.D. Reprint, 1891.

A Case of Fracture of, and Dislocation between, the Tenth and Eleventh Dorsal Vertebræ, with Presentation of the Patient. By Alfred I. Bouffleur, B.S., M.D. Reprint, 1891.

The Operative Treatment of Appendicitis. By Thomas S. K. Morton, M.D. Reprint, 1891.

Trap Siphonage and Trap-seal Protection. By James M. Denton, M.E. Reprint, 1891.

Manual of Physical Diagnosis: for the Use of Students and Physicians. By James Tyson, M.D. Philadelphia: P. Blakiston, Son & Co., 1891.

Bald Heads. By Albert E. Carrier, M.D. Reprint, 1891.

A Clinical Report of Operative Surgery, in the Service of William T. Bull, M. D. By William B. Coley, M.D. Reprint, 1891.

A Treatise on Practical Anatomy, for Students of Anatomy and Surgery. By Henry C. Boenning, M.D. Illustrated. Philadelphia and London: F. A. Davis, 1891.

Records of the Association of Acting Assistant Surgeons of the United States Army. Edited by W. Thornton Parker, M.D., Recorder A. A. A. S. Salem, Mass.: Salem Press Publishing and Printing Co., 1891.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM NOVEMBER 10 TO NOVEMBER 16, 1891.

HALL, WILLIAM R., *Captain and Assistant Surgeon.*—Relieved from Fort Schuyler, N. Y., and assigned to duty at Angel Island, Cal.

CLENDENIN, PAUL, *Assistant Surgeon.*—Promoted November 5, 1891, to be Assistant Surgeon with the rank of Captain, after five years' service, in accordance with the Act of June 23, 1874.

FISHER, HENRY C., *First Lieutenant and Assistant Surgeon* (recently appointed).—Ordered to Fort Riley, Kansas, for duty.

SHAW, HENRY A., *First Lieutenant and Assistant Surgeon* (recently appointed).—Ordered to Fort McKinney, Wyoming, for duty.

DUNLOP, SAMUEL R., *First Lieutenant and Assistant Surgeon* (recently appointed).—Ordered to Fort Sill, Oklahoma Territory, for duty.

KIEFFER, CHARLES F., *First Lieutenant and Assistant Surgeon* (recently appointed).—Is assigned to duty at Fort Sheridan, Illinois.

MERRIWETHER, FRANK T., *First Lieutenant and Assistant Surgeon* (recently appointed).—Is assigned to duty at Fort Adams, Rhode Island.

TEN EYCK, BENJAMIN L., *Assistant Surgeon.*—Is granted leave of absence for one month, to take effect about the 15th inst.

MEARNS, EDGAR A., *Captain and Assistant Surgeon*—Is relieved from duty at Fort Snelling, Minnesota, and assigned to duty at Fort Mackinac, Michigan,

WILLCOX, CHARLES, *First Lieutenant and Assistant Surgeon.*—Is relieved from duty at Fort Bowie, Arizona Territory, and assigned to duty at Fort Gaston, California.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING NOVEMBER 14, 1891.

GATEWOOD, J. D., *Passed Assistant Surgeon.*—Detached from the U. S. S. "Despatch," and granted two months' leave of absence.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U. S. MARINE-HOSPITAL SERVICE, FOR THE TWO WEEKS ENDING NOVEMBER 7, 1891.

VANSANT, JOHN, *Surgeon.*—To proceed to New Orleans, La., as Inspector, November 7, 1891.

MURRAY, R. R., *Surgeon.*—To rejoin station at Key West, Fla., October 30, 1891.

PECKHAM, C. T., *Passed Assistant Surgeon.*—To proceed to Memphis, Tenn., as Inspector, November 7, 1891.

GUITÉRAS, G. M., *Assistant Surgeon.*—To assume command of Gulf Quarantine Station, October 30, 1891.

DECKER, C. E., *Assistant Surgeon.*—Assigned to duty at San Francisco, Cal., October 30, 1891.

APPOINTMENT.

DECKER, CHARLES E, of Michigan.—Commissioned as Assistant Surgeon, by the President, October 27, 1891.

TO CONTRIBUTORS AND CORRESPONDENTS OF THE MEDICAL NEWS.

THE MEDICAL NEWS begs its contributors and correspondents to observe the following:

1. Contributors of original articles, lectures, clinical memoranda or hospital notes, will, upon publication of their communications, be liberally paid, either

a. In cash, or

b. In reprints (250).

It should be distinctly stated, either at the head of the communication or in the accompanying letter, which method is preferred.

2. Copies or abstracts of papers must not have been or must not in the future be furnished any other journal, or published elsewhere, unless the fact have been clearly stated prior to the acceptance by us of the article. *Without an understanding to the contrary, it is held to be a matter of simple honesty that communications sent* THE NEWS *are for its exclusive use.*

3. The rejection of a manuscript does not necessarily imply any adverse editorial judgment as to its literary or scientific value. There are many other reasons that often prevent the acceptance of a manuscript. It may, for example, be rejected because another and similar article upon the same subject has already been accepted and awaits publication; because it could not be published for so long a time that it would become unseasonable; because it would more appropriately appear in some other journal, etc., etc. We cannot undertake to explain the especial reason for not accepting a paper.

4. The probability of the acceptance of an article, as well as the likelihood that it will be extensively read, is greatly enhanced by its brevity. Useless introductions and more useless perorations are always well omitted. Expression should be condensed; not so much as to exclude or to render obscure important things, but sufficiently to economize the time of the busy and tired practitioner and save mental friction in clearly comprehending the article. The results of good thinking, good observation, or good work, can be given in few words—and, with certain rare exceptions, it is results that medical men want.

5. THE NEWS especially desires brief, crisp clinical memoranda and short, concise articles on living subjects—articles epitomizing observations and facts occurring almost daily in the practice of every practitioner. A vast deal of material highly valuable to medical science and to humanity is constantly lost because busy men feel that they have not the time or ability to write elaborate papers. This is wrong. Everyone has some peculiar experience, sees exceptional aspects and phases of disease, has peculiar abilities or methods of practice, comes repeatedly upon a highly anomalous, suggestive, instructive, or interesting case. If such cases were properly placed on record, medicine would be greatly advanced. THE NEWS desires to become the medium of such publication and record.

6. Communications should be prepared in compliance with the following suggestions:

a. Paper larger than 8 × 10 inches should never be used.

b. The paper should be good, white writing paper, not news or tissue-paper.

c. If possible, a manuscript should be type-written.

d. Only one side of the paper should be written upon.

e. A blank margin, at least one inch wide, should be left at the left-hand side of the sheet.

f. Communications should be written in black, non-copying ink.

g. Writing, and especially all proper names, should be distinct and plain.

h. A sheet on which many corrections, interlineations, etc., have been made, should be rewritten.

i. If possible, manuscript should never be folded or rolled.

7. Communications in reference to subscriptions, advertisements, or other business should be addressed to the publishers, MESSRS. LEA BROTHERS & CO., 706 and 708 Sansom Street, Philadelphia. Communications pertaining to the reading columns should be addressed to the Editor:

GEORGE M. GOULD, M.D.,

ORIGINAL ARTICLES.

CLINICAL REMARKS ON A CASE OF ACUTE MILIARY TUBERCULOSIS.

BY WILLIAM PEPPER, M.D.,

PROFESSOR OF THE THEORY AND PRACTICE OF MEDICINE IN THE UNIVERSITY OF PENNSYLVANIA, PHILADELPHIA.

MR. J. E. F., twenty-eight years of age, was admitted to the University Hospital on September 28, 1891. He was a farmer and had enjoyed good health until two years ago, when a horse fell upon him. He was in bed a few days on account of sprains and bruises from this accident, and three weeks subsequently had an irregular febrile attack, which was called "typhoid malaria." Unfortunately, we cannot be sure that this irregular fever was not symptomatic of some local trouble in the chest, resulting from the severe injury. He got better and enjoyed fair health until October, 1890, when, after a spell of influenza, he went back to work, but soon broke down and was not well afterward.

He had a cough all winter, with scarcely any expectoration; he had a sense of weight and of fulness in the left side and occasionally some pain about the lower part of the left chest. In May he had an acute exacerbation of pleuritic trouble, with sharp pain in the left side, and was confined to the house for a month. Almost every day he felt a sense of chilliness, followed by fever, but he rarely sweated. One year ago he weighed 160 pounds, but on admission to the hospital he weighed only 117 pounds.

From the time he was admitted to the hospital, on September 28th, to the date of his death, October 18th, he presented frequent and irregular febrile paroxysms. At intervals of one or two days the temperature would suddenly rise from 99½° or 100° to 102½°, 103°, or even 104°. This rise would occur in a few hours and would soon be followed by an equally abrupt fall, attended with only a moderate amount of sweating. These paroxysms were not at all controlled by large doses of antiperiodics. Repeated careful examination of the chest showed evidences of circumscribed pleural effusion in the lower part of the left chest, posteriorly. Elsewhere, both on the left and right sides, there was ample resonance on percussion, but the respiratory murmur was feeble and the vocal resonance and fremitus seemed less than normal. There were some small crackling râles over the lower lobe of the right lung, posteriorly. There was very little cough, and the only expectoration was a trifling amount of grayish gelatinous mucus. This was repeatedly examined for tubercle bacilli, but with negative results.

I may, indeed, anticipate here by saying that, on the very last day of life, a specimen was obtained that showed a few bacilli, but, of course, this was too late to be of any guide in diagnosis, as the microscopic results were not obtained until after the autopsy had been made. The heart's action was rapid, weak, and somewhat irregular. The apex-beat was feeble and diffused. There was a soft, systolic murmur over the body of the heart. The urine was normal, the liver was not enlarged, and the spleen was only moderately so.

In explanation of the paroxysmal fever, naturally the first and most hopeful suggestion that occurred was that a circumscribed empyema existed on the left side; but when, on October 3d, I tapped the chest, I obtained twenty-four ounces of clear, deep-reddish fluid that, under the microscope, showed many red blood-corpuscles, a few leucocytes, and small oil globules. Its reaction was slightly acid, the specific gravity 1016. On boiling, it almost solidified. Careful examination showed no tubercle bacilli.

The occurrence of hemorrhagic effusions in the chest is most frequently encountered in cases of malignant disease of the pleura; it is decidedly rare in tuberculosis. The absence of bacilli is to be specially noted. Of course, the character of this fluid did not help to explain the peculiar paroxysmal fever present. The possibility of ulcerative endocarditis was necessarily taken into consideration. No history could be obtained of cardiac disease, and the murmur present was soft and certainly not of organic nature. It is true that the spleen was somewhat enlarged, but there were no evidences of emboli and the urine was free from albumin or casts.

The patient's strength failed rapidly, the breathing became more and more rapid and shallow, the pulse very rapid and feeble, and death occurred on October 18th. The post-mortem examination revealed complete obliteration of the pericardial sac by old and dense adhesions that, of course, had interfered seriously with the action of the heart. There was no organic disease of the valves, so that it was clear that the murmur heard over the heart had been functional and dependent upon irregular or defective ventricular action. The left chest presented extensive lesions of old pleurisy with dense layers of organized and false membrane that had recently become the seat of miliary tubercles. Both lungs presented throughout the most typical lesions of acute disseminated miliary tuberculosis. The minute nodules were separate and remained in their recent gray, translucent condition. Everywhere they were separated by alveolar structure. At the lower extremity of the small intestine there was an area of fungous ulceration almost encircling the bowel and extending fully two inches up from the ileo-cecal valve.

It is difficult to say what was the initial lesion in this interesting case. Not improbably it was the pleurisy on the left side, which may have resulted from the accident, and which had been the cause of the irregular fever that was called "typhoid malaria." There had been very little cough, considering the long-standing extensive lesions in the chest, and expectoration was almost entirely absent up to the last. The ulceration of the intestine seems to have caused no diarrhea; there was no history of looseness, and while he was in the hospital the bowels were rather constipated.

There are many impressive lessons to be learned from the case. Not the least important is the extreme caution with which our new and exquisitely delicate means of diagnosis are to be employed. The very fact that one has an instrument of precision disposes to unlimited confidence in its operation. This is right when the observation is made with care, and when it gives positive evidence in the affirmative. It is very different when it gives negative evidence. Thus, had the examination of the sputa shown tubercle bacilli, the diagnosis would have been cleared up at once. There was a temptation to attach too much importance to the repeated failure to detect bacilli. An ophthalmoscopic examination should have been made, but this was overlooked. In not a few cases of acute malarial tuberculosis I have derived great assistance from finding retinal tubercles. This same caution must be observed in the use of many of our new, delicate diagnostic tests. It is eminently true of the chemical examination of the contents of the stomach.

The heart murmur, taken in connection with the enlargement of the spleen and the absence of bacilli from the pleural liquid and from the sputa, raised the interesting question of the possible existence of ulcerative endocarditis. One meets with the same paroxysmal type of fever in this disease, but the heart symptoms are usually more marked than they were in this case, the spleen is larger, evidences of septic embolism are common, and in particular the urine nearly always shows albumin and casts. Everyone knows how obscure are the physical signs in many cases of acute miliary tuberculosis. The lungs will present innumerable minute nodules disseminated throughout their tissue, and yet prior to death there may have been good percussion resonance, absence of râles, and at most a marked feebleness of respiratory murmur, with some impairment of vocal fremitus and resonance. But then, as in this case, the disturbance of breathing is out of all proportion to the demonstrable lesions, and this of itself should excite suspicion. It is true that, in this case, the matter was complicated with the existence of the pleural effusion on the left side and the adherent pericardium. This seemed to go far in explanation of all the symptoms except the paroxysmal fever. The influence of pericardial adhesion in causing a cardiac murmur without valvular lesion was well illustrated.

Upon the whole, the case seemed a most interesting and instructive one as an illustration of acute tuberculosis, with a great enhancement of the difficulties of diagnosis that often surround that fatal malady. The date at which the rapid tuberculous development took place in this case cannot be determined, but everything indicates that it was quite recent.

THE ETIOLOGY OF STOMATITIS APHTHOSA.[1]

BY F. FORCHHEIMER, M.D.,
OF CINCINNATI, O.

THE term aphthosa, as old as Hippocrates, has caused more confusion than any other in the nomenclature of diseases of the mouth. Even at the present day, so much or so little may be included in the term aphtha that, for the sake of precision in diagnosis, the word should either be entirely dropped or its meaning so clearly defined that there can be no reasonable room left for error. Without going into the subject historically, which I have done elsewhere, it will be well to state here that the aphthous form of stomatitis referred to is that disease first defined by Bohn. To Bohn belongs at least the credit of first having published the views of other authors besides himself, which finally culminated in making a precise clinical picture of stomatitis aphthosa. If we could adhere to this, and it seems both feasible and practicable to do so, we would have a definite term for a clearly defined clinical picture. If, on the other hand, any ulceration of the mouth, any small loss of substance in the mucous membrane, is called an aphtha—as has been done and is being done—we shall never arrive at any exact conclusions.

Stomatitis aphthosa is a disease characterized by general and local disturbances—the general disturbance in the form of fever and other constitutional symptoms, the local disturbance as an eruption of aphthæ. The aphthæ (and in this I differ somewhat, though not essentially, from Bohn) are to be looked upon as vesicles modified by the locality in which they appear, *i. e.*, the mouth. They are also changed by the action of moisture, being constantly bathed in saliva from the irritated mouth. When, as is not infrequently the case, the eruption also appears upon the skin around the mouth, there can be no doubt of the nature of the eruption; and if, as I have shown latterly in one case, applications of warm water are kept up constantly, the history of these vesicles will be the same

[1] Read at the meeting of the American Pediatric Society, held in Washington, September, 1891.

as that of those within the mouth. In brief, then, we would call stomatitis aphthosa a vesicular eruption in the mouth, with certain constitutional symptoms.

The cause or the causes of this disease have eluded detection. Without disregarding the opinions of others, there is always one special pet view on this subject. Perhaps the greatest number of authors are agreed in ascribing this disease, like all others, to those glittering generalities that are so well known to all of us in connection with the etiology of children's diseases. The one calls it struma, the other scrofula, the third malnutrition, the fourth tuberculosis, and so on *ad infinitum*. I am not prepared to say that unhealthy children are more predisposed to this disease than healthy ones. Whatever our theoretical views may be regarding the vulnerability of children otherwise affected, my observation has led me to believe that the general condition of a child, so far as we can see, has nothing to do with an attack of stomatitis aphthosa. That there is an individual predisposition, I firmly believe; in what this consists I do not know. Children in the best of health will sometimes have an attack without apparent cause. Teething, as well as everything else, has been accused of producing this trouble. It can hardly be out of place to say that this view is simply based on the *post hoc ergo propter hoc* method of reasoning. If we were to accept everything that follows or accompanies the coming through of teeth as being produced by dentition, we had better close the book, so far as the etiology of disease for the first three years of life is concerned. It can be proved beyond a doubt that aphthæ are not tuberculous, therefore not scrofulous or strumous. There is a rare form of tuberculous stomatitis, so rare that every case ought to be recorded; but, so far as I am able to learn, it has nothing in common with the trouble we are now discussing. It is quite certain that no evidences of tuberculosis have been found in all the bacteriological investigations made by others, as well as by myself. As usual, "catching cold" has been charged with the cause of this disease. So little that is positive can be said in this direction that the less we say the better.

After these general causes are disposed of, the most common belief is probably that aphthæ are always due to a deranged stomach. This is a very natural view, because, as a rule, aphthæ are associated with some derangement of the alimentary canal. The routine practice is about as follows: ulcers in the mouth—positive indication for rhubarb, calomel or hydrargyrum cum creta. A careful examination of each individual case will prove that the child was ill before the sore mouth came on—that, as it were, the gastro-intestinal symptoms represented a sort of period of invasion for the disease. No one would for a moment believe that the eruption of scarlatina comes from a deranged stomach, although of all diseases it is most frequently preceded by vomiting. Errors of diet are so common in childhood that it is almost impossible to exclude them in searching for the causes of disease. I have seen three children in the same family have an attack of aphthous stomatitis: in the older two, errors of diet could be taken into consideration; in the third, as he had taken nothing but sterilized milk, this was impossible.

Yet we are constantly confronted with the statement that the child's stomach has been deranged for the last few days, and that now the ulcers have appeared there certainly must be some connection between the two. It is almost impossible to conceive of the mucous membrane of the mouth being affected by continuity from that of the stomach; the nervous connection is a very remote one; but the clinical fact remains as already stated. If the alimentary canal is primarily the cause of the trouble there is but one explanation, and that is that a something is excreted by the saliva that causes these ulcers to be formed. But, for various reasons, the mechanism is not so simple for aphthæ; it might be given as an explanation of the existence of those small follicular ulcers so common with some patients, and would possibly be satisfactory; in aphthous sore mouth there is another factor that seems absolutely essential.

For the last ten years the view has been gaining ground that stomatitis aphthosa is the manifestation of the foot-and-mouth disease in cattle. This view was first brought forward by Sagar in 1764 and has been corroborated by many observers in various parts of Europe. (See Bollinger: *Ziemssen*, vol. iii, p. 581.) Hertwig (1834) was the first to prove the connection by direct experimentation; he and three other physicians drank infected milk, and all three were attacked by stomatitis aphthosa; in Hertwig's case the eruption also appeared upon the hands and feet. These results were verified by Jacob in 1846. On the other hand, a great many authors, of whom Cnyrim is the last, have had occasion to give their evidence on the other side of the question. It must be confessed that the number of observers who have been able to verify this connection is steadily increasing, and that the view itself is being more generally accepted. This would place the affection in the class of infectious diseases. Admitting that this view is correct for Europe, according to my information from veterinary surgeons and their literature it could not be true for this country. Foot-and-mouth disease is an exceedingly rare disease in this country—indeed, it is claimed by some that no well-authenticated case is on record. From the report of the United States Treasury Cattle Commission, 1883 (*Amer. Vet. Rev.*, vol. vii), I learn that an invasion

of foot-and-mouth disease swept over northern New York and New England in 1871. In 1883 diseased cattle were landed in New York by two ships (the "France" and the "Nessmore") employed to carry cattle, and the cargo, which was returned to the other side, became infected on board, as the period of incubation seems to be only thirty-six hours. This and other previous experiences (see a long correspondence, *Report Department of Agriculture*, "Diseases of Animals," Washington, 1881) gave rise to the idea, held in Europe, that the foot-and-mouth disease may originate in this country. In 1884 Dr. A. A. Holcombe (*Vet. Review*, vol. viii) reported an epidemic in Kansas, but ill-effects in human beings are not mentioned. In the same year Geo. H. Bailey, D. V. S., reported an epidemic in Portland, Maine, brought in by Hereford cattle. These are the only records of epidemics in this country that I have been able to find; it is claimed by veterinary surgeons that no case has ever originated in this country, and by some, as has been stated, that no well-authenticated case is on record.

However this may be, I have taken the trouble in every instance to look into the milk-supply, and have questioned the surgeon in attendance at the dairies from which the milk-supply has been obtained, always receiving the answer that there never had been a case of foot-and-mouth disease in Cincinnati. Infection would be the most rational explanation for the causation of the disease, and in order to determine whether there could be a contagium vivum, I have had the aphthæ examined bacteriologically, all precautions being observed and all the various methods being employed. The result, when positive, was to show the presence of pus-producers, and of nothing more.

Dr. Eugene Fränkel (*Virch. Archiv*, Bd. cxiii, 111) describes the process as a pseudo-diphtheritic one (Weigert), practically agreeing with Baginsky (1884), who found microörganisms, cocci, and a few bacilli. Fränkel examined three cases bacteriologically, in two of which he found the staphylococcus pyogenes citreus (Passet), and in the other the staphylococcus pyogenes flavus (Rosenbach). He hastens to the conclusion that these organisms are the cause of the disease, although he has never succeeded in producing any lesions by inoculation in lower animals, thus disregarding one of the most important evidences as to the pathogenic nature of an organism.

If we accept the view of the causal relation of foot-and-mouth disease and stomatitis aphthosa, and if we reject such a connection for this country, we are left the choice of two conclusions: either we do not have stomatitis aphthosa, or the disease may be produced by more than one cause.

In regard to the first assumption—the non-existence of the disease in this country—I believe everyone will agree that we see as well-defined cases here as can be seen anywhere in Europe. I am sure that I have seen as well-marked aphthæ in my own clinic as I have abroad. The variety of the low forms of life found shows, either that we have not found the pathogenic form, or that their invasion is a secondary process, due to the existence of a soil made fertile by the aphthous process. In foot-and-mouth disease any abraded surface may become affected, so that both a local as well as a general infection must be accepted; whether both causes be the same cannot be proved at present. Cases are on record in the human being, in which, upon the drinking of infected milk, the eruption also appeared upon the hands (Hertwig). In these cases the eruption must certainly have been due to general and not local infection. In the absence of pathogenic forms, we must look for some chemical agent that can be carried into the circulation, producing an eruption upon the mucous membrane as well as upon the skin. Purely theoretical as this may seem, it has been accepted by dermatologists for many skin diseases (eczema, herpes), and only awaits conclusive proof in the isolation of these bodies, which will become possible with the further advances in animal chemistry.

Now, taking for granted that a chemical body, formed in foot-and-mouth disease in cows, carried by the milk, produces stomatitis aphthosa in the human being; that we have stomatitis aphthosa in the absence of this foot-and-mouth disease, the inevitable conclusion must be that more than one cause can be found for this disease. Possibly, when bacteriological methods will have become still better developed, a lower form of life may be found as the first cause of this disease; but for the present this view seems untenable, especially as it has been proved that inflammation may be caused by other agents than lower forms of life. (Grawitz, Buchner, and others.)

In addition, we must be reminded of the fact that aphthæ are frequently associated with other diseases: pneumonia, intermittent fever, gastro-intestinal disturbances, the acute exanthemata, etc., so that the position of multiple causes becomes very much fortified. It seems out of the question to accuse a local cause, although wounds and burns may produce lesions that cannot be distinguished from aphthæ. In this direction, therefore, there seems nothing left but the acceptance of some general causes as indicated. The question would arise: How do these causes produce lesions in the mouth?

It has always seemed to me that aphthæ were nothing more or less than the eruption of herpes. The reasons for this are as follows: If we make an artificial aphtha (Gerhardt, Bohn, and myself) by

any cause that would produce a vesicular eruption upon the skin, the lesion is identical with the one we find in stomatitis aphthosa. In a great many cases of stomatitis aphthosa we find herpes facialis, the eruption being continued from the mucous membrane to the skin; and lastly, the diseases in which herpes occurs most frequently are those in which we commonly find that form of mouth trouble. If we take a vesicle and develop it in the mouth, it will, as has been stated before, undergo the same changes as an aptha. In brief, then, the etiology of stomatitis aphthosa, in the great majority of instances, is to be studied as the etiology of herpes non-parasitica. Dermatologists regard herpes, especially herpes zoster, as a disease of nervous origin (Bärensprung, Kaposi, Sattler, and others); this would include the herpes secondary to other diseases, for no one can claim for the herpes facialis of pneumonia that it is a zoster—occurring, as it usually does, upon both sides of the face in children (Thomas). The same can be said of stomatitis aphthosa. It does not follow the course of any one nerve exactly, although in the majority of instances the eruption will be found along some branch of the fifth pair of nerves, especially the lingual. Verneuil (*Annales de Dermatologie*, 1885) states that herpes may be of traumatic origin. When a nerve is injured the eruption will appear at its peripheral distribution.

In those cases, then, in which we have been able to find the pathological lesion of herpes, it has been found to be some irritative change in the ganglion from which the nerve arises, or in the nerves themselves. Naturally, there must be a something that produces this lesion, and it would not be an unreasonable supposition to look for this something in the form of a body the result of bacterial activity, or of some faulty process in the digestive apparatus. A similar process, not exactly analogous, will be found in diphtheria, in which the Löffler bacillus produces the local manifestations and the toxine the remote ones. If we take the poison of foot-and-mouth disease, this will represent the toxine of diphtheria, already formed, which, absorbed from the intestinal tract, produces the general disturbances, and finally the aphthæ, as the result of irritative changes in the nerve-ganglia. This something, called ptomaïne by the modern French writers, does not require for its origin the presence of microbes. It may have its origin within the body, as the result of a perverse digestive process within the alimentary canal, the liver, or even during the process of reduction, within the circulation.

Parrott and Erb were the first to have claimed that herpes might be looked upon as an infectious process, and Hardy (1885), Delétang (1886), Landouzy (1883), and Feulard (*Dictionnaire Encyclopédique des Sciences Médicales*, 1888), have continued the theory, Feulard arriving at the same conclusions that I have here expressed.

Nothing more can be claimed for this view than that it is an hypothesis, with many things necessary to be proved before it can become susceptible of positive proof. The original poison must first become isolated, then detected in the circulation, and, finally, it will have to be proved that this poison is capable of producing aphthæ.

But if we grant the connection with foot-and-mouth disease—and at present this conclusion is the result of clinical observation only—it would seem that there is justification for the view already expressed. Although so much is left to be proved before this view can be accepted, we are, nevertheless, justified in expressing it, though purely the result of observations in the various forms of herpes and deductions from these observations.

The last etiological factor is contagiousness. Aphthæ will be found in several members of one family at the same time. I have had occasion to observe this in several instances. This is the only evidence that could be brought forward to prove the contagious nature of the disease. It would seem more natural, however, to claim that the same cause had been operating upon these various members of the same family, although the aphthæ will not appear on the same day in each individual. The latter fact could be readily explained by taking into consideration the varied susceptibility of individuals, and the quantity or quality of the poison introduced into each of these individuals.

In conclusion, I would sum up the results as follows:

1. Stomatitis aphthosa is a disease produced by some form of deleterious material in the circulation.
2. This material may have its origin in various processes, bacterial or otherwise.
3. It may, therefore, be of various kinds.
4. This material acts upon a nerve or nerves, or upon a nerve-center or nerve-centers.
5. It produces an herpetic eruption that is the aphthous process.

PARALYSIS FOLLOWING MEASLES.

Based Upon Forty-one Cases.

By HERMAN B. ALLYN, M.D.,
INSTRUCTOR IN PHYSICAL DIAGNOSIS IN THE UNIVERSITY OF PENNSYLVANIA; CHIEF OF THE DISPENSARY FOR DISEASES OF WOMEN AND CHILDREN, ST. JOSEPH'S HOSPITAL.

The influence of acute febrile diseases in the production of palsies did not escape the observation of some very early writers. Anyone that feels an interest in the historical aspect of the subject will be amply rewarded by consulting the series of remark-

able articles by Imbert-Gourbeyre.[1] James Lucas,[2] however, was the first, so far as I have been able to discover, to report, in sufficient detail to make it of use clinically, a case of paralysis following measles. The patient was a woman, twenty-three years old, and the palsy a paraplegia. An interesting fact connected with this case is that nine years previously the patient had developed the same symptoms following an attack of variola.

All writers on the subject are agreed in declaring that paralysis as a sequel of measles is very rare. Thus, Parrot told Landouzy[3] that he had never seen a single case, though for ten years he had had the opportunity of making observations in a hospital in which measles reigned *en permanence*. In Wallenberg's[4] series of 160 cases of cerebral palsy, 9 are said to have followed measles; but the number should be 8, for Bourneville's case is recorded twice (Cases XXIX and XXXII). Gowers has met with 7 cases, Rilliet and Barthez have reported 1, and Osler[5] and John Abercrombie[6] each 4. Altogether I have been able to find only 41 cases, one of which I observed myself.

Spinal palsies, as a rule, are much more frequent among children than are cerebral palsies. During a period of time in which 120 cases of the latter visited the Infirmary for Nervous Diseases in this city, there were nearly 500 of the former (Osler). But the large majority (about 35) of the cases of palsy following measles collected by the writer have been cerebral. This preponderance of cerebral over spinal cases may be more apparent than real—that is to say, it may simply have been my fortune, though I think not, to find more of the former than of the latter.

The clinical differences between cerebral and spinal palsies are well marked. In the former there is paralysis with spasmodic movements; the reflexes are exaggerated, but the electrical reactions remain normal, and wasting does not develop quickly or attain an extreme degree. In spinal palsies, on the contrary, the palsy is associated with rapid wasting, the reflexes are soon lost, and marked changes in the electrical reactions occur, while rigidity is absent.

The forty-one cases collected furnish sufficient data for a study of infantile palsy following measles.

The onset of the disease is abrupt. It is generally marked by a convulsion, or by a derangement of consciousness varying from simple drowsiness to coma. The latter appears to have been the mode of origin in my own case. There may be a single convulsive seizure or a series of seizures. In Bernhardt's[1] case convulsions occurred nearly every eight days for three months. In Bourneville's[2] case the initial attack of convulsions lasted seven hours, and the convulsions recurred two months later. Sometimes the convulsions are at first general, while the extremities of the affected side are rigid and contracted. This was the condition in Bateman's[3] case—the left side was paralyzed, and in the intervals of the convulsions the right extremities were in continual motion.

In a number of cases the disease develops without convulsions, or with convulsions so slight that they have entirely escaped observation. My own case is an example of this, and for convenience will be reported here.

A boy, thirteen months old, developed measles of moderate severity about May 13 or 14, 1890. As the eruption faded, catarrhal pneumonia manifested itself. When convalescent from the latter, on May 30th, between three and five o'clock in the morning, it was discovered that he was paralyzed on the left side. There had been no palsy during the preceding afternoon and evening, for he had been able to move both arm and leg perfectly. When seen on the following morning, the child was in a condition of partial stupor, and was turned partly toward the right side. The right eyelid could not be opened voluntarily. The pupils were contracted. The left arm and leg were flaccid and motionless; when raised they dropped like lead. The left foot was rotated outward and rested on its external border; the toe was pointed and the heel elevated. There was anesthesia of the affected side. When the features were wrinkled, the left side of the face remained motionless. There was slight elevation of temperature; the pulse was irregular in rhythm; the breathing was Cheyne-Stokes in character, but not noisy.

By the first of June, some contracture of the left fingers was noted, with beginning return of power. The child had begun to suck, the pulse improved, but the breathing remained much as it had been. From this time on, power slowly returned in arm and leg, but the contractures persisted, and the face continued paralyzed. At the present writing (November, 1891), the child shows considerable improvement, most marked in the facial palsy. There is increased power in both arm and leg, and absence of contractures. The nutrition of the child is in excellent condition, but it has an insatiable appetite, and its mental condition is not encouraging. Speech is much affected, the child being very slow in acquiring words, and articulation being poor.

In Scheper's[4] case, the onset was marked by coma, which persisted nearly for three days. When this dis-

appeared, the child (eight years old) was unable to speak. The sensorium was intact, and replies to questions were made by movements of the head. The child was unable to stand, but could move the limbs. Coördinated movements were impaired: the child could not take a cup directly to its mouth, but would carry it to the brow. In this case recovery was remarkably rapid—paresis rather than palsy existing. In fifteen days the patient began to talk, the voice being nasal and high-pitched; it could then also stand and take things better—improved coördination.

In Baxter's[1] case the onset was accompanied by delirium. Slight palsy was just perceptible at the height of the disease, but the palsy became more marked as the febrile symptoms abated, so that on the fifth day the child was totally incapable of moving any of the muscles of the right side. The muscles on this side were flabby, insensitive, and of a lower temperature than in health. In this case also recovery was rapid, being complete on the twenty-sixth day. Baxter believed the rapid recovery to be attributable to the administration of nux vomica.

Following immediately upon the convulsion or coma, palsy or paresis is detected in the muscles of the affected side, or, in the case of paraplegia, in the affected limbs. At first the affected parts are flaccid, and more or less anesthetic. If recovery is very rapid there may be no development of rigidity, with contractures. When the latter develop, sensibility has already become restored.

In cases of palsy of spinal origin, the onset is free from either convulsions or coma. In Perret's[2] case, the patient, after an ordinary attack of measles, believed himself well, when he suddenly perceived considerable feebleness of the lower limbs. For five days he could move his limbs in bed only with much difficulty, and it was absolutely impossible for him to stand erect. At no time was there pain in the affected parts. Retention of urine induced him to enter the hospital, where Perret saw him. Beyond a little pallor he presented the appearance of health. The reflexes were intact and so was sensation. He dragged the feet a little in walking, and they did not feel solid under him. There were no evidences of muscular atrophy. Nothing particular was noted regarding the arms. The patient had to be catheterized regularly, and there was occasional incontinence of feces. Speech was not altered; there was no nystagmus, no appreciable trembling of the head or limbs. Improvement was steady and rapid.

In ascending spinal palsy the onset is more gradual. In Bergeron's[2] case, the patient entered the hospital August 23, 1867. By September 1 the palsy began to be sharply defined. Muscular contractility in the lower and upper extremities was diminished, swallowing was difficult, the voice nasal. By October 14th, under tonics and electricity, the patient appeared to have improved, but on the next day he was worse and the palsy was ascending. On attempting to swallow, food passed into the trachea. Two days later it is stated that the lungs had lost their normal contractility, and that mucus accumulated in the bronchial tubes and throat. The sphincter ani was paralyzed, the face was pale, the pulse 136, the respiration 52. Death resulted from slow asphyxia.

Liégard[1] was more fortunate with his case. The patient, a boy, two years and three months old, developed measles, after having had an exhausting diarrhea for fifteen days. Between five and six weeks after the attack of measles began, palsy was first noticed by the mother. Nine days later the condition was as follows: In addition to great weakness of the upper and lower extremities, the head fell forward on the chest, from palsy of the muscles of the back of the neck. This symptom was manifest and had been gradually increasing for two days. Deglutition at the same time became more and more difficult; mastication also was interfered with. The skin appeared to be insensitive to puncture and to pinching. Improvement in the condition was gradual and steady. Less than three months after the palsy developed it is stated that the patient was as well as though he had never been sick.

The symptoms in Barlow's case[2] of early disseminated myelitis are interesting. The patient was a man, twenty-three years old. The eruption of measles occurred June 10, 1885, and by June 13th it had begun to fade. There was a slight systolic murmur at the apex; the pulse was 76. The only complaint on the part of the patient was of soreness referred to the sternum, since June 11th. At midnight of June 13th, the man was unable to pass his urine. The temperature rose the next evening to 103.8°, and on the next morning it was 103.2°. The patient was very drowsy, irritable when roused, and speedily again lapsed into drowsiness. The pupils were sluggish, the grasp of the hand was weak, the limbs were immovable, but sensation was preserved. There was no rigidity and no knee-jerk. The systolic murmur already spoken of persisted. The patient retched, but no actual vomiting occurred. On the morning of June 15th there was less drowsiness, but in other respects the man was worse; he could speak only in a whisper; the fixed pain in the breast-bone was still present; the urine was retained; cyanosis gradually developed, and death occurred at 9 P.M., June 15th, five days after the appearance of the eruption of measles.

As regards the type of palsy following measles, the paraplegic is said by Landouzy to predominate; whereas palsy of the velum palati and of the muscles of the neck is peculiar to diphtheria, while in intermittent fever the type is that of right hemiplegia with aphasia. Again, the more or less permanent paraplegias are seen, he says, especially as a sequence of typhoid fever and of dysentery, palsy following scarlet fever being cerebral more often than spinal and peripheral. I cannot confirm or disprove the accuracy of Landouzy's statements as to the other diseases mentioned, but he is wrong so far as measles is concerned. Here the type is certainly cerebral, and most frequently it is hemiplegic.

The paralysis usually appears during convalescence, and most frequently from the latter part of the first week to the close of the third week after the onset of the attack of measles. Of twenty-one cases that are reported in sufficient detail to give the information, eleven developed the symptoms of palsy between the fifth and the sixteenth day, while five more probably belong to this period from the fact that the palsy is said to have occurred "during convalescence" (three times), "on the twelfth day after the disappearance of the eruption" (once), and "at about the time of the disappearance of the eruption" (once). In the remaining cases, three developed convulsions on the second day of the eruption, one a month after the onset of the measles, and one in from five to six weeks.

The duration of the cerebral palsy depends upon the severity of the attack. In six cases it was between sixteen days and eight weeks. Disturbance of speech persists longer than the other evidences of the nervous lesion. In one case there was still such disturbance at the end of nine months, and in another case, aphasia lasted for two years. In Sympson's[1] case, a girl, three and a half years old, developed aphasia and right hemiplegia in connection with an attack of measles, and when thirteen years old speech was still imperfect and there was atrophy of the right extremity. It is evident that in many cases the lesions are permanent, and Bourneville's[2] case, which will be referred to later on, leaves no doubt that the future of the child is clouded by the possibility of epilepsy.

One case of spinal paraplegia (Lucas) is said to have lasted more than a week, and one of atrophic spinal palsy six months. In a case of cerebral paraplegia the duration is set down as from two to three weeks. Barlow's case of disseminated myelitis resulted in death in five days, and a case of ascending spinal palsy recovered in three months. In Bateman's case the patient survived the first attack, the dangerous symptoms subsiding in five weeks. Subsequently convulsions reappeared, and death ensued three months after the onset of the disease.

Our knowledge of the pathology of infantile palsy is far from complete, but much, nevertheless, has been learned through the careful observations of Gowers, Ross, Osler, Bernhardt, Wallenberg, and others.

So far as birth-palsies are concerned, it is certain that hemorrhage, frequently meningeal, is the cause of the palsy, and that difficult labor in many cases accounts for the hemorrhage. In the palsy following an infectious disease, however, the pathology is more obscure, for the great majority of the patients do not die in the attack, and when death occurs at a more or less remote period the morbid conditions found are secondary to a still unexplained primary pathological process.

Palsy following measles is not a mere coincidence. It is less frequent than palsy following diphtheria and scarlet fever, but it is universally admitted that there is a connection of cause and effect between the two. Strümpell has suggested that the morbid process is an inflammation, an encephalitis of the cortex, similar to that present in anterior poliomyelitis, or infantile spinal palsy. But as the palsy is in a number of cases complete, and yet of transient duration, it is difficult to believe that in these cases there has been inflammation. Encephalitis, nevertheless, should be considered one of the causes, for Barlow has reported one case of disseminated myelitis following measles, the diagnosis having been confirmed by autopsy with careful microscopical examination; and if myelitis can occur, why not encephalitis?

In cases in which organic heart-disease exists, embolism is a possibility. But heart-disease is rarely present, and Osler declares that the ten specimens in the museum of the Elwyn institution constitute evidence against the embolic theory.

The blood transmits the poison of measles to all parts of the system. The eruption is seen upon the fauces before it appears upon the body, and the catarrhal pulmonary symptoms are in all probability due to the presence of the eruption upon the mucous membrane of the respiratory tract. It may be that in carrying the poison the bloodvessels themselves become altered in their structure, so as to permit of extravasations of serum or blood. If the amount be very small and reabsorption be very rapid, we can understand how the palsy may be transient; or it may be that an inflammation of the arteries is set up, as a result of which the blood is withdrawn from certain areas. Osler suggests that a widespread arteritis might initiate a sclerosis, and, if suddenly developed, a porencephalus, and sclerosis and porencephalus are lesions found at autopsies in cases of

[1] Brit. Med. Journ., 1890, vol. i, 283. [2] Loc. cit.

infantile palsy. Gowers thinks the probable cause of the palsy is thrombosis of the cerebral veins and of the sinuses. While this occurs in infancy, I do not know of a case in which it has been demonstrated by autopsy in infantile palsy.

The fact that most of the cases of palsy following measles occur in about the second week of convalescence seems to indicate that a change has been taking place in the arteries, dating from the active stage of the disease, and that when this arterial change reaches a certain point, we have an apoplexy, a leakage of serum, or an occlusion of a number of arteries from general arteritis. In Barlow's case we may suppose that the specific poison of measles escaped from the bloodvessels, for the disseminated myelitis was present almost, if not quite, from the onset of the disease, which ran its entire course in five days.

From two cases that have come under my observation, I am the more inclined to believe that the poisons of measles and other eruptive fevers tend to destroy the integrity of the bloodvessels. In the first, a young man, twenty-three years of age, with phthisis of the left apex not far advanced, was suddenly seized with most profuse hemorrhage. In the course of forty-eight hours he must have lost two quarts or more of blood. Previously to the hemorrhage he was without fever, was gaining in weight, and stood a good chance of recovery. Considering the condition of the lung, I was at a loss to account for the hemorrhage. Following the latter, the temperature was continuously high, and on the eleventh day a copious eruption of measles appeared. The hemorrhage in this case appears to have marked the beginning of the incubation-period of measles, and the poison of that disease, added to the existing disease of the lung, was sufficient to determine a hemorrhage.

In the second case, a child, four years old, was seized on the third or fourth day of scarlet fever, when the rash was already much faded, with profuse hemorrhage, apparently from the lungs. When I saw the child the next day, no focus of disease in the lung could be discovered. About a year before this time the child had had disease of one lung, which I feared at the time was tuberculous, but it had recovered, and no pulmonary symptoms existed before or during the attack of scarlet fever.

On the other hand, it is possible that the specific poison of measles, bacterial or other, acts by exciting an inflammation in the cells of the motor area of the cerebral cortex, and in the ganglionic cells of the anterior cornua of the cord.

As, in the great majority of cases, the palsy occurs during convalescence, it might be supposed that this was simply a manifestation of profound muscular weakness resulting from an exhausting disease. This supposition, however, would not be supported by the facts. In most of the cases the attack of measles has been of mild or of only moderate severity, and nothing is said to indicate that the patients were in a depraved state at the time of the attack. In Perret's case, for example, the patient, a robust, very muscular man, became aware of his palsy for the first time when, cured of his measles, he essayed to get out of bed.

While the palsy following measles cannot be ascribed to exhaustion, there is reason to think that special susceptibility to nervous affections is a predisposing cause. In Lucas's case, the patient, on the ninth day of an attack of measles, had paraplegia with incontinence of urine and feces, and she had had precisely the same symptoms nine years before, following an attack of variola. Perret, moreover, is inclined to think that his patient's susceptibility to paralytic influences may have been brought about by his habit of drinking three quarts of wine a day.

The prognosis is good as regards life. In only four of the cases is death said to have occurred. One of these was a case of disseminated myelitis, and one a case of ascending palsy. From this alone it would appear that the spinal palsies are more fatal than the cerebral. But such a conclusion is probably unjustified. Deaths may have occurred later and not have been reported.

The severity of the onset indicates the severity of the lesion, and the rapidity of recovery indicates to a certain extent the degree of ultimate recovery. When the left hemisphere is involved, aphasia may be a symptom. It is usually one of the last symptoms to disappear, and in a modified degree it may be permanent. While the prognosis is good as regards life, yet, when the palsy does not disappear speedily and completely, the possibility of epilepsy and subsequent imbecility must be borne in mind. Epilepsy may be deferred several years. In Bourneville's case, the child had measles when six years old, and epilepsy developed when it was between eight and eleven years old.

Repeated convulsions increase the gravity of the prognosis, both as regards life and as regards recovery of power in the palsied members. It would appear that epilepsy is most likely to occur when convulsions have appeared at an interval, say, of several months from the initial attack.

The treatment of palsy following measles is naturally divided into that of the convulsions or coma ushering in the attack, and that of the results of the nerve-lesion. To control the convulsions the patient's head should be elevated and cold applied. The bowels should be opened by calomel, followed, if possible, by a saline laxative. The bromides and chloral are appropriate, and the latter may be given by the rectum. In coma much the same treatment

is suitable, but if there is reason to believe that the coma results from exudation, ergot and belladonna are to be preferred to the bromides and chloral.

As regards the paralyzed members, much can be done to keep up the nutrition of the muscles until the affected nerve-cells have recovered themselves, or until their function has been assumed by other cells. The limbs are usually colder than normal, and should be kept warm by a layer of cotton-batting. Daily massage is of very great service, and should be persisted in for months. Mothers are more likely to follow directions in this particular if they have something to rub in, and if a confidence on their part is expressed in goose-grease, it will be prudent to recommend it. Any unguent will do as well, but, of course, the rubbing and the manipulation are the most important factors.

Faradization of the affected muscles is also of very great service. To obtain the best results, both it and massage need to be kept up with the utmost patience and perseverance for many months. The leg and face usually recover first, the arm last and least.

The spastic paraplegias, such as existed in the two cases of Holmes Coote,[1] and in which there was an approach to the development of equino-varus, have been dealt with by orthopedic surgeons. My impression is that the results have not been encouraging.

The brain-lesions themselves, consisting as they do of sclerosis and porencephalus, offer very little to warrant surgical interference. In a few cases the sclerotic area may admit of removal. As in all chronic nerve-disorders, potassium iodide should be tried; it may be of some service if small doses are administered for a long time.

THE TREATMENT OF INGUINAL HERNIA.

BY ALEXANDER DALLAS, M.D.,
OF NEW YORK; CONSULTING SURGEON TO BAYONNE HOSPITAL.

ALTHOUGH numerous articles are constantly appearing on the subject, the treatment of hernia has not kept pace with the recent advances in other branches of surgery; and to-day there is no subject of like importance in which there is so little interest taken and consequent want of knowledge displayed by the body of the profession. It is still too much the custom among physicians to consign their ruptured patients to the tender mercies of the druggist or truss-maker, who is totally ignorant of anatomy, and whose only object is to effect a sale. To prove the correctness of these statements it is only necessary to examine the methods of treatment in use at the present time, and as these methods naturally divide themselves into the palliative or mechanical, and the radical or surgical, we will first take up the palliative. In the palliative treatment of hernia, trusses of various shapes have been used in all ages to prevent the protrusion of the gut, and, if possible, to effect a cure, and the appliances used to-day are virtually the same as those used a century ago. They are all constructed on the same general principle—a powerful spring, a large pad, and a strong strap, and keep up the rupture by the same means—brute force. The application of the retaining force in these trusses is wrong. When applied laterally, as by the usual method, it is used at a disadvantage, and greater pressure has to be employed, while the pad is bound to slip down until it rests upon the pubic bone. When applied from below upward the greatest pressure is at the lowest point, and the injury to the spermatic cord and vessels is intensified. The shape of the ordinary pad, too, is an anomaly, and its usual method of application is unscientific. Its convex surface, driven into the parts by the powerful spring, and kept in constant motion during walking, etc., bores its way into the hernial opening and actually enlarges it. Another equally serious objection to these trusses, and one which has been entirely too much overlooked, is the fact that, in every case, their point of greatest pressure is at and below the external ring, where there is only integument to prevent the pinching of the spermatic cord and vessels between the pad and the pubic bone. We freely admit the evils due to pressure upon the uterine nerves, and we should no longer ignore the equally serious and positive injury due to pressure upon the spermatic vessels, and which gives rise to well-marked symptoms. Recently flat pads and elastic belts have been introduced, but the flat pads only increase the pressure at their lower edges, and elastic belts intensify the injury by the constancy of their pressure.

Forced by these considerations, I have devised for my own patients a truss that appears to meet all requirements. It is light and cool. It rests upon the pelvis—an immovable support. There is no constricting band around the hips to cause atrophy of the muscles and interfere with every movement. There is, consequently, no excoriation to heal up, as the pad is not disturbed. The belt comes down along the flank, breaking the lateral recoil that causes the protrusion, and so acting as an auxiliary to the pad. The pad itself is small, somewhat diamond-shaped, with its surface slightly concave, the better to adapt itself to the convex abdominal walls. The pressure, applied from above downward, is slight and wholly over the internal ring. Running from the center of the face of the pad to its lower edge is a gradually-deepening groove that prevents compression of the vas deferens and spermatic vessels and nerves.

[1] Hardy et Behier: Path. int., iv, 1880.

But there are cases of hernia in which palliative treatment is not sufficient, and in which more radical measures have to be resorted to. Sometimes the hernia is so large or so painful that the patient is disabled; while, in other cases, an operation is desired by the patient or undertaken at the suggestion of the surgeon. For these cases many operations have been devised by different operators, but we are virtually reduced to the consideration of what may be called the American operation. Introduced by a prominent surgeon, and adopted by his followers, it soon became the rage, and, for the time being, has displaced other and better methods. Naturally, we look for points of excellence in it beyond those of the others, but we fail to find them. In performing it all the safeguards that Nature throws around the canal are cut away and packed together in a heterogeneous mass, leaving only a thin layer of fascia and the peritoneum. On this fascia grow granulations which it is claimed form an unyielding cicatrix strong enough to resist protrusion. Now, in other parts of the body we are taught that cicatricial tissue rapidly disappears under pressure and motion, and we direct our treatment accordingly. (We see a proof of this also in the frequency of hernia after laparotomy, and, should a recent suggestion of Tait's be carried out, the number will be largely increased.) And yet we are asked to believe that this particular cicatrix, subjected to incessant pressure and motion from its very inception, will remain firm and unyielding. Is it any wonder, then, that we see so many cases in which the cicatrix has become so thin that the movements of the intestines can be seen through it, with a protrusion so large that no ordinary truss can hold it, and with a sensitiveness so great that no pressure can be tolerated? The victim of this operation always reminds one of the man in the parable, in which we are told that "the last condition of that man was worse than the first." Fortunately, there are better operations than this, but whatever method be adopted, the surgeon should be able to guarantee his patient that, whether successful or not, his condition will not be made worse than it was. The operation that I believe will give the best results with the fewest drawbacks is as follows: Make the first incision along the pubic bone, commencing at the symphysis, and extending outward from three to four inches; then carry a second incision upward at almost right angles to the first, and parallel with the inguinal canal. Dissect up this triangular flap of skin freely, and turn it back, and the whole field of operation is exposed. (Occasionally it may be necessary to make a third incision down over the scrotum.) Dissect down to the sac in the usual way, loosen any adhesions, push the sac well up inside the internal ring, and fasten it to the external portion of the internal ring with strong catgut sutures, bringing the sutures out above and tying them there. Then bring the pillars of the ring together with several sutures, check all oozing, put in a small drainage-tube, turn down the skin flap, and thoroughly coaptate the edges, and you have virtually a subcutaneous wound. The adhesion of the skin over and around the canal gives a firmness to the parts that they so much need; the sac acts as a pad to divert the protruding gut; the approximation of the pillars narrows the canal to its normal dimensions; the resiliency of the now closely adherent, unbroken skin helps in a measure to prevent further protrusion, while there is no external cicatrix to be irritated by the truss that it is always advisable to put on after the operation.

Midway between the palliative and radical treatment of hernia comes the old Heaton method of injecting into the hernial sac an irritant solution to excite adhesive inflammation. With ordinary precautions, and in properly selected cases, this is perfectly harmless and has given fairly satisfactory results. If the irritant be used in powder form the results are even more satisfactory.

When speaking of the indications for radical treatment I said nothing of strangulated hernia, a class of cases that figure largely in hospital reports, and give a high death-rate. All authorities claim that in a considerable proportion of these cases reduction is impossible and operative interference compulsory. This I no longer believe. In all the years of my practice, part of the time surgeon to works employing thousands of mechanics, amongst whom such cases are frequent, I have never had to operate for strangulated hernia, nor had I ever any trouble in reduction since adopting my present method. When called to a case of this kind I at once give an injection of morphine and atropine, to which latterly I add a little cocaine. I repeat this injection every ten or fifteen minutes until the patient is quite comfortable. Meantime I make him drink every five minutes from a half to a cupful of a mixture consisting of: Strong black coffee Oj, fluid extract of ergot ʒij–ʒiv, and occasionally a little strychnine. Generally, within a half-hour the rupture has become flaccid, and gentle taxis reduces it. I use no anesthetics or hot baths, or external applications, and have reduced cases when other physicians have failed. Of 545 recorded cases of strangulated hernia, 260 died. Of these 260 at least 250 could have been saved by the above treatment.

Professor Benedict, of Vienna, has been elected an honorary member of the Norwegian Society of Physicians, of Christiania.

Dr. C. Wedl, Emeritus Professor of Histology at Vienna, recently died at the age of seventy-six.

WIRING THE SPINOUS PROCESSES IN POTT'S DISEASE.[1]

BY B. E. HADRA, M.D.,
OF CHICAGO.

IMMOBILIZATION of the vertebræ by wiring their spinous processes to each other is a suggestion thrown out in connection with a report of the same procedure in a case of vertebral fracture. The spinous processes of the vertebræ are firmly held together, and when it is considered that there will be no slipping of the wire if the inter-spinous ligaments and the adjacent muscular structures are preserved, and that three or more vertebræ can be wired, it becomes evident that a resistant posterior brace—so to say—can be established, throwing the body-weight on it, and thereby relieving the vertebral bodies. A second gain is the separation of these latter from each other, or from the inter-vertebral cartilages, which, according to the laws of leverage, obviously must follow. The vertebral bodies will thus be prevented from pressing and rubbing on each other. If this be so, the question arises: Under what circumstances is this method called for? In my opinion, it should be tried as soon as any deviation of a vertebra is discovered. It then will not only do what I have claimed for it, but it will also better prevent permanent disfiguration than any other method, because it is more direct than any other. But if an abscess-cavity has already formed, the surgeon will have to decide whether or not its dimensions are too great to be filled up by new bone-formation. If the abscess-cavity is too large, it may be better to allow the diseased surfaces to come into contact and to unite by bony ankylosis with kyphosis. Under such circumstances the wiring will be out of place. Not so, however, if the destruction of the bodies and of the inter-vertebral discs is moderate. We may then hope for the reproduction of a sufficient amount of bone, and by holding the spine in a straight line we shall obviously enforce a desirable final outcome.

The proposed operation does not exclude other and later operations, such as draining, scraping, etc. As can easily be imagined, it may even become a very useful addition to them. For instance, it may greatly assist in keeping the drainage track patulous. Perhaps, also, before bony ankylosis has set in, moderate kyphosis could be reduced by careful extension and manipulation, and the gain afterward secured by wiring.

It is hardly necessary to point out the advantages the suggested method would offer over all others at our disposal. It would do away with all the annoyances of the apparatus, of the long confinement to bed, and of a number of other troubles connected with the usual treatment. But, as a matter of course, it has to be proved to be practicable, effective, and, above all, free of danger. I know from my one operation (though it was for fracture), and from experiments on the cadaver, that the wiring can be done with the greatest ease, so as to be within the reach of the average surgeon. In children the bones may not be strong enough to withstand the grip of the wire, but three or more processes may be included, and thus a greater resistance obtained. As to the direct danger of the surgical procedure as such, I think nothing is to be feared, as may be inferred from the short description to be given.

A median skin-incision is made over the objective spinous processes. I would advise making it rather too long than too short. Now, the long muscles on either side are longitudinally incised with as little laceration as possible, and held aside with retractors—just sufficiently to allow of a good view of the outlines of the spinous processes. Then, with a strong, curved needle carry the silver wire through the inter-spinous spaces above and below the processes to be wired, in a figure-of-8 fashion, as often as is deemed necessary. Then fasten the ends of the wire by twisting, and close the wound. In lumbar operations simple loops around the processes are sufficient, as the processes stand nearly horizontally, and slipping is therefore not to be expected.

Whether in old cases, with much contortion or kyphosis, when no bony ankylosis has taken place, a division of the ligaments will assist rectification or not, I am not prepared to state. I think the possibility that contracted ligaments can stand in the way of reduction cannot be denied.

Finally, it is well to remember that the needle must not enter too far away from the middle line; otherwise injuries to the nerve-trunks may be inflicted.

ORIGINAL LECTURE.

INCUBATORS—GAVAGE—INFANTILE SYPHILIS—HYSTERIA AND SPURIOUS WOMB-DISEASE—SCHUCKING'S OPERATION—OPERATION FOR LACERATED CERVIX WITHOUT ANESTHESIA—RECTO-VULVAR FISTULA.

A Clinical Lecture
Delivered at the Philadelphia Hospital, October 24, 1891.

BY BARTON COOKE HIRST, M.D.,
OBSTETRICIAN TO THE PHILADELPHIA HOSPITAL, AND PROFESSOR OF OBSTETRICS IN THE UNIVERSITY OF PENNSYLVANIA, PHILADELPHIA.

I PRESENT to you this morning a premature baby, born at least two months before term, and in such a feeble

state that we had to supply it with artificial heat. There are several ways of supplying artificial heat for these premature babies, but it is best accomplished by means of a specially constructed apparatus called an incubator. The one you see here was devised by a Frenchman named Auvard. It is a rather cumbersome arrangement, and would hardly be available for private work, although for hospital-practice it is very good. We can keep an even temperature in this incubator at almost any desired height up to 100°. In the treatment of babies born very prematurely the temperature should be kept between 95° and 100°. This child, although born two months before term, became somewhat acclimated by exposure for a week or two after birth, and so when it was brought into the hospital and placed in the incubator with the temperature raised to 100°, it seemed to suffer from the heat, as it was constantly bathed in perspiration. We now keep the temperature a little lower than 90°, and in that temperature the infant seems to be comfortable.

In the management of premature infants it is occasionally necessary, in addition to supplying artificial heat, to see to an artificial ingestion of food. Such infants are too feeble to nurse in the usual way, and their food must be put into their stomachs. We do this by means of a rubber-tube passed into the stomach, to the end of which is attached a funnel, into which the mother's milk, in dram doses, is poured. This procedure goes under the technical name of gavage. We have had some difficulty in securing human milk for this baby, and were obliged for a while to resort to artificial feeding; during that time the infant went down hill rapidly, and, if we had not secured a woman whose breast could be milked, it would have died. When it first entered the ward it weighed three pounds. Its weight increased five ounces at first, but fell to two pounds and fifteen ounces on the artificial food. We finally found a woman who was willing to allow us to milk her breasts for the child, and the weight began to go up. Since yesterday it has gone up half an ounce; to-morrow I expect to find the weight again increased, and we shall look for a steady rise in weight until the child presents as healthy an appearance as we could expect in any infant born at the natural time and reared in the natural way. As to the results of this treatment in general: In a six months' baby we get successful results in about 22 per cent. of the cases. A six months' baby is, of course, an extreme instance. In a seven months' baby we get success in a larger proportion—in about 38 per cent. of the children. These statistics are from Paris. It seems to me that we obtain somewhat better results at this age than are obtained in the Paris hospitals.

Before dismissing this case let me call attention for a moment to the construction of the two incubators most in use at present. The principle of this incubator is simple enough, although its construction is somewhat complicated. It is a double wooden box, one within the other; there is a compartment for hot water within the outer box and beneath the inner box. The water contained in cans should be almost boiling and changed about every half-hour. Within the inner box—that is, in the upper compartment—lies the baby. We keep a thermometer lying inside, so that we can tell whether the temperature keeps steady, and the child is protected from the external atmosphere by a glass lid perforated by a chimney.

The second incubator I show you here is made after the German pattern, devised by Crédé, of Leipsic: it is simply a double-walled bath-tub of tin or copper, with a space about two inches wide beneath the walls for hot water, which is renewed every four hours.

If exposed to the sudden changes of the atmosphere these babies would almost surely die. Their vital processes are so feeble that they do not furnish a sufficient amount of body-heat to maintain cell-action. We carry about with us a normal temperature of about 98° and over, because there are within our bodies cell-activity and cell-combustion that furnish us with this temperature in spite of any external changes in the atmosphere.

In private practice a specially constructed incubator is not usually to be procured. The physician must supply the premature infant with artificial heat as best he can; consequently he does not get as good results as are obtained in hospitals. My plan in private practice is to put the baby in the bath-tub which has been provided for it, after filling the tub half full of cotton-wool. A mass of cotton-wool is then placed over the infant, leaving a space for respiration, and between the cotton and the sides of the tub are placed a number of medicine or beer bottles filled with hot water. In this way one can keep up about the child a constant high temperature, if the hot bottles are renewed frequently enough. It requires, however, the constant attention of the nurse or other intelligent person.

I present to you next a case of infantile syphilis that, unfortunately from the clinical teacher's point of view, has done so well that it is not half as good a case for demonstration as it was a day or two ago. The skin-eruption has improved so rapidly under treatment that the case is no longer typical. There is, however, enough left on the back to show something of the character of the eruption, and the improvement demonstrates the good results of the treatment. As you notice, there is in this case a trace of the syphiloderm on the soles of the feet and palms of the hands. This is a characteristic situation for syphilitic skin-affections in young children. When I first saw this infant a week ago it presented a much more characteristic appearance, and the efflorescence had a peculiar copper color. I found that the child had been treated by mercurial inunction, a very common plan of treatment, but without much benefit. In addition to this, mercury was ordered internally in the form of calomel, beginning with one-twelfth of a grain twice a day, and the improvement has been wonderful. We have a very good substitute for calomel in mercury with chalk, which is not so aperient. The success of treatment in this case justifies Henoch's assertion that, with the internal administration of calomel, specific eruptions in infants can be, so to speak, wiped off the skin as one erases a chalk-mark on a slate.

Here is a patient of a kind that you will often see in your private practice. She presents a form of disease in connection with which you must be on your guard against a very common mistake. I shall develop her history before you to show you how easy it would be to make a mistake in diagnosis if too much reliance be placed upon a woman's statements and beliefs when she is possessed with the idea that she has "womb disease."

I shall read you her history as I obtained it yesterday. About a year ago she found that she was unable to work as well as before. After a little while she found it impossible to go up and down stairs upon her feet, and she was obliged to go up and down sitting upon each step. After a while even this mode of locomotion became impossible, and she spent the whole day upon the lounge. After about three months of this sort of thing she felt something "rip in her back," and with this symptom she had a profuse dark discharge from the vagina. In addition to these symptoms she had a great deal of abdominal pain, worse when she attempted to walk, so that she went to bed and has been there ever since.

She has been under the care of physicians in her own home, a town in the interior of the State, who have "doctored her for womb trouble." So long as she was treated for the womb trouble she felt perfectly well, but was still unable to walk. So soon as the treatment ceased the pains returned. She described the pains as neuralgic, or as "stitching" pains, in the lower part of the abdomen. This is the history in the main that this patient presented to me yesterday, and it is a very typical history indeed, with one exception. In my experience these women usually have the name of some definite disease of the genitalia, the symptoms of which they may describe with surprising accuracy, or they believe themselves the subject of some peculiar and impossible disease of the womb; for example, I saw yesterday in consultation a woman who said that she had a tumor of the womb, six inches long and two inches wide, which her former physician, a homeopath, had been removing inch by inch.

On examining this woman before you, I find her genitalia perfectly normal, with the exception that her womb is somewhat undersized. It is, as you will have already recognized, a case of pure hysteria with imaginary womb disease.

When a woman goes to a general practitioner with such a history, he too often jumps to the conclusion that there must be some uterine or ovarian disease. His inability to find anything on vaginal examination is ascribed in his own mind to lack of skill in making a gynecological diagnosis, which he is afraid to confess. Or perhaps some slight abnormality is discovered that the physician honestly believes to be the cause of the woman's troubles. Finally, the physician may be an unmitigated rascal who trades on his patient's gullibility and too great readiness to believe anything that is told her about her womb or ovaries. In any case the unfortunate patient is treated by the introduction of the sound and by applications to the endometrium, until she very likely acquires some inflammatory process about the womb, which permanently impairs her physical condition and prevents the repair of her nervous system. My experience with these nervous women who present symptoms of uterine and ovarian disease—and it has been considerable in the Orthopedic Hospital and elsewhere—leads me to the conclusion that the majority of them have nothing abnormal in the genitalia, except often an ill-developed womb. It is an interesting fact that many a case of ill-developed nervous system will show ill-development of the genitalia as well. There is a minority, however, in which the hysteria rests upon a basis of disease in the pelvic viscera. These cases are most distressing. Their hysteria will not, as a rule, improve until the pelvic disease is removed, but an abdominal section is a peculiarly dangerous operation in such women. A large proportion of them die from shock and sepsis, even in the hands of the best operators.

Women like this one before you, if you inquire carefully into their history, will almost always give you an account of some grief, some nervous shock or strain. That was so in the present case. The nervous system lacks vigor and resisting power often by reason of bad training from childhood, often as the result of heredity. Nervous strains that you or I could bear, crush these inadequately equipped individuals. The balance-wheel of their nervous system is destroyed, and their nerves run riot. There is not one of us that has not the impulses, perhaps ill-defined, of these hysterical creatures, but our reason and will-power restrain them. Every woman's attention is attracted to the genitalia by the recurring menstruation and by slight symptoms of pain or discomfort at intervals, and every woman must have felt at moments that there might be something wrong in the genital region. These fears, however, a clear reason and a strong will dissipate. Not so with the hysterical woman. Her attention, once attracted to a possible ill, dwells upon it until the unreal becomes subjectively the real. It is not by treating the imaginary complaint, but by dealing with the fundamental disorder that such a woman can be cured.

I have a patient in the wards upstairs whom I would like to bring before you, but to do this is at present inadvisable, because she is suffering from chronic diarrhea, and I do not care to risk exposure to the cold, so I will simply describe the case. She is a woman who has a complete prolapse of the uterus, in addition to the chronic diarrhea, and perhaps as a consequence of it. When she goes about on her feet the uterus drops altogether out of her body, carrying with it the inverted vagina and the bladder. Operations for the relief of these patients have long been the opprobrium of gynecology. The plastic operations for the contraction of the vagina are often failures. The same judgment must be passed upon operations for shortening the round ligaments, and upon stitching the uterus to the abdominal walls. Moreover, this last procedure is distinctly dangerous, and therefore unjustifiable.

A woman can live indefinitely with a prolapse of the uterus. It is uncomfortable, even distressing, but not dangerous to life; therefore it is not right, in my opinion, to operate for this affection when the operation entails a certain risk of life, and by no means insures relief. The conscience of the gynecologist is apt to be callous on this point, so that he should guard himself with care against yielding to the temptation of performing abdominal section on too slight grounds.

Three years ago an operation was devised by Schücking for chronic retro-displacement of the womb. This operation consists in passing a thread into the uterine canal, through the anterior uterine wall at the fundus, and through the vaginal wall at the anterior vault. This is accomplished by a concealed needle, which I exhibit to you. You see the instrument is a hollow uterine sound with a good curve and a long handle. Within

the sound is the needle, which, being threaded, is passed to the fundus uteri within the sound, and is then pushed forward by this little catch on the handle until it comes into sight at the anterior vaginal vault. The thread that it carries is drawn out a little so as to make a loop, through which is passed the ligature-thread. The needle is then withdrawn, and the instrument removed from the uterus. The ligature-thread will then be seen with one end hanging from the anterior vaginal vault, and the other end coming from the os uteri. If these two ends were tied together the uterus would be pulled into a position of anteversion, and even anteflexion. There would, however, be considerable cutting of the cervix and vaginal mucous membrane by the ligature, which must remain in place several weeks. To prevent this, the ends of the ligature are each passed through a button, and then either clamped with a perforated shot or tied. It is well to remember that a clamp-shot will not hold a stitch if there is much strain put upon it. You can clamp a shot upon a silkworm-gut or a silk suture with all your force, and still be able to pull it off with the greatest ease. This operation has been done more than two hundred times (two hundred and seventeen at the last report) in Germany, and a few times in this country by one operator, Dr. Boldt, of New York. After a thorough trial, which has proved its efficacy in backward displacement of the uterus, it has been tried lately for prolapse of the uterus. Five women have been operated upon with perfect success. In one the uterus was exceedingly large and totally prolapsed. In two cases I believe the patients have been field laborers, and have resumed their hard labor after the operation without suffering a recurrence o the prolapse.

Theoretically, the "vaginal fixation" of the uterus, as it is called, would seem to be a rational treatment for prolapse. As long as the womb is held anteverted its descent through the vaginal canal is improbable. And, moreover, the fixation of the fundus at the anterior vaginal vault to the connective tissues between the bladder and uterus by adhesive inflammation would seem to be an additional safeguard against descent. Clinical results, however, constitute the crucial test, and I shall watch the outcome in this case with great interest. The operation that I propose to do in a day or two has not, I believe, been done before in this country. I shall report the result to you after sufficient time has elapsed to enable me to judge whether the prolapse has been permanently cured.[1]

Our next patient has heart-disease in the shape of mitral insufficiency; she has been suffering with bleeding piles, and has in addition to her other troubles a very badly lacerated cervix. The cervix is split to the vaginal vault on both sides, and there are present local and reflex symptoms that are often associated with this condition. I have had her under general treatment with digitalis, on which she has improved considerably, and I have treated the hemorrhoids with suppositories of tannic acid, iodoform, and extract of belladonna, and with the ointments of galls and belladonna in equal parts. The woman is very much improved; the heart has become stronger; the disturbance of circulation has been diminished, and the piles have been much improved. The cervix remains, of course, as it was.

I have determined to operate on the cervix without giving ether, as I am afraid of an anesthetic in view of the heart-disease. The woman is perfectly prepared to suffer a little pain. There are many hospitals in which this operation is always done without an anesthetic, as the cervix is an insensible part of the body, and can be "insulated," to use a Teutonism, as no other part of the body can be, without extreme pain. The operation for a lacerated cervix is easy to perform, and ought not to consume much time.

I have evolved a technique of my own in this operation, as everyone does after a little personal experience. It is as follows: The lips of the cervix are seized with double tenacula made after my own pattern, and are widely separated; the area to be denuded is then marked out with two or three strokes of a knife. This area is then denuded on both sides by a few clips with Emmet's scissors; the entire denudation is completed in about two minutes. The stitches are next introduced, beginning at the upper angles of denudation, using for this purpose stout semi-circular needles. The two stitches below on either side are inserted with straight needles. As a rule, six stitches are quite enough, but it is well to have ready two more in case the tips of the cervical lips need more accurate apposition. The ligatures of silkworm gut are clamped with perforated shot, and just before each shot is run home a stream of water from an irrigator is directed upon the wound. During the ten days that this patient will lie in bed we shall proceed with the treatment of her heart-affection, and shall endeavor to relieve her internal piles. We shall try to send the woman out of the hospital in just as good a condition as possible, and there is no reason why she should not live in comfort for a number of years, if she can avoid hard physical labor, and can find some suitable occupation as, for example, that of a seamstress.

I have devised the following plan for carrying my gynecological instruments. I keep them in a metal box, which, when taken apart, furnishes me with two metal pans, very convenient for the antiseptic solutions used in preparing the instruments for operation. In private practice, the most convenient antiseptic fluid is boiling water, which I use as an antiseptic whenever practicable.

[1] The operation was performed by Dr. Hirst in the gynecological ward, following the plan described in the lecture. The Schücking needle was passed into the uterine cavity concealed in its tube. The uterus, seized by a tenaculum, was drawn down toward the vulva and well backward; the needle was then pushed through the entire extent of the uterine wall at the fundus until it appeared in the vagina; the thread with which it was armed was seized and drawn out so as to make a loop by which to carry a stronger thread back again through the uterus; this being accomplished, the end projecting from the os uteri was threaded in a needle and passed through the anterior lip of the cervix. The operator then took two perforated plates of lead, about a half-inch in diameter, and, passing the threads through the perforations, clamped them with heavy shot. In this way the uterus was fastened at the level of the anterior vaginal vault in a position of extreme anteversion, and to some degree of anteflexion. It is to be hoped that the operation will prove a success, as seems likely to be the case, for the first step in the prolapse is always the retroversion of the uterus. After the long axis of the uterus is brought in coincidence with the long axis of the vagina the descent of the uterus follows easily. All that can be seen after the operation is a couple of lead plates, one in the anterior vaginal vault, and the other on the anterior lip of the cervix.

As I denude the cervix you will notice that the patient scarcely winces until I approach the vaginal vault, where the tissues are more sensitive. You notice that I leave at least a quarter of an inch of undenuded mucous membrane down the center of each lip, internally, so that the restored cervical canal shall be of good caliber. I was once obliged to artificially dilate the canal after an operation of this sort performed by another surgeon.

Care should be taken not to cross the stitches; if this should be done the circulation below will be cut off, the tissues will slough, and the patient might suffer serious consequences. Six stitches are enough in this case. The cervix, you will observe, is restored to its natural conical shape, and there is no longer a gaping of the lips, with the exposure of delicate mucous membrane, which was never intended to be subjected to the constant irritation of exposure to external influences.

The woman has stood this ordeal remarkably well. She does not complain of the pain of cutting and stitching, but of the dragging down of the uterus. The main reason for giving ether in these cases is to secure greater relaxation of the vaginal canal and outlet, so that the operator can work conveniently and to the best advantage.

The next patient I present to you is a woman who gives us a history very similar to that of the hysterical patient whom I have just shown you. She is a girl, twenty-two years of age, who complains of pain all over the abdomen and insists that her womb is out of place. She claims that at times it falls out of her body. She is firmly convinced that she is suffering from some uterine trouble. I made an examination yesterday and found that she had a slightly retroverted uterus of a rather infantile type. There never could have been the slightest degree of prolapse. She made such a fuss about the examination and held herself so rigid that it was impossible to find out just what was the matter, if anything, beside a slight grade of retro-displacement. She lies in bed all day, refusing to get up; she will not answer questions unless we insist upon it, and she has that peculiar vacant, sad, introspective expression that is characteristic of melancholic patients. Her mind is fully made up that she has serious uterine trouble. I will be able to tell you in a moment whether she has anything worth complaining of or not, as we shall anesthetize her. On etherization I find that there is not a thing the matter with this woman's pelvic viscera. Her uterus is slightly retroverted, but this condition makes no real difference, for the uterus is of the infantile type which, as I have explained to you in studying the other hysterical patient, is so frequently found in hysterical girls. This is a case of hysteria, and the woman should be sent to the wards for nervous diseases. These women come to the receiving-ward here and give a distinct account of womb trouble that deceives the hospital-physicians just as it often deceives the general practitioner.

This woman, if she had money, would very likely go from physician to physician to be treated for her imaginary womb trouble, until in consequence of repeated intra-uterine examinations and applications, she might in reality acquire a septic inflammation of the pelvic organs that would permanently destroy her health.

I next exhibit to you the result of an operation I did here two weeks ago for a recto-vulvar fistula, the result of a kick upon the vulva inflicted by the woman's husband. There was a tear an inch or more in length, running across the floor of the vestibule, the edges of which I denuded and sewed up. Union has occurred in the angles of the wound, but not in the middle. The wound burst open for some reason or other nine days after the operation. Up to this time all the feces passed by the bowels, but on the ninth day the woman complained that the feces were again passing by the vagina. When the resident physician came to remove the stitches he found only five of the seven that had been inserted; on inquiry, he learned that the patient herself had pulled out two of them. From this history I presumed that she had been pulling on the stitches and is herself responsible for the imperfect result, although she tells me that she did not interfere with the wound until she felt the feces coming through the vagina. This is the first time I have failed of success in an operation of this kind, although it is quite common not to get complete union in one operation for fistula, and so I do not feel discouraged. In cases of very extensive vesico-vaginal fistula I almost always expect to operate two or three times. There is a woman in the hospital on whom I operated for a vesico-vaginal fistula large enough to admit three fingers that had resulted from pressure exerted upon the vaginal walls by a pessary that had been allowed to remain in the vagina too long. The first operation secured about an inch of union; I operated again and secured half an inch more, and the third operation cured the woman perfectly. A short time ago I performed a like operation on a woman who had a very extensive opening into the bladder, the result of a mismanaged labor. She had been in labor some three days when the physician in charge applied forceps and used great violence in the extraction of the child, which was dead. The perineum was horribly torn, and a few days after labor the urine began to dribble through the vagina. There had been a slough of the anterior vaginal wall in consequence of the prolonged pressure of the head upon it. The cause of the difficulty was a rhachitic pelvis that had never been discovered. In this case I closed the greater part of the opening in the first operation, but shall be obliged to operate again to effect a cure. There are cases on record in which women have been operated upon some sixteen or eighteen times. It is a consolation to know that a cure can be secured in the vast majority of cases with patience and persistence.

In the present case, as some of you may see, there is but a small opening left in the center of the former tear, which does not compare in size with the original opening, and which I am convinced will be successfully closed by the next operation. I shall advise the woman to go about on her feet for a few days before again operating and confining her to bed. It is my custom after these operations to keep the bowels freely opened every day. This I did after the first operation and shall do again, as I am convinced that the results are better than by the old plan of locking the bowels up for a week or more with opium.

Professor Borgsiekiewicz, of Innsbruck, has been called to the Chair of Ophthalmology at Gratz.

CLINICAL MEMORANDA.

THE USE OF TOBACCO IN INTESTINAL OBSTRUCTION.

BY W. D. JONES, M.D.,
OF RISING CITY, NEB.

I HAVE searched the literature at my disposal to secure the most reliable information regarding the therapeutic uses and applications of that much-abused weed—tobacco.

Almost every author of a materia medica or therapeutics gives tobacco only a passing notice of its applications, usually followed by so positive assertions regarding its dangers that the average student and practitioner dismisses the subject with fear and trembling.

While it is evident that, like most of our drugs, this must be used very cautiously and with a thorough appreciation of its application to proper cases, it seems that a great deal of the danger feared from its employment is groundless.

My observation and practical experience in the therapeutic applications of tobacco have been confined to its employment in the treatment of strangulated omental hernia, hepatic and renal colic, and fecal impaction of the large bowel. Properly and judiciously employed, I consider it one of the most efficient remedies of a palliative character available by the practitioner for treating cases of fecal obstruction of the intestines.

In a former number of THE MEDICAL NEWS I have specified its application, assisted by gravitation, in the treatment of strangulated omental hernia, with the report of a case. To be of marked benefit, it must be applied *ad nauseam*. Owing to the depressing nature of the drug, it should not be employed in cases of young children or in delicate adults.

CASE I.—I was called in consultation to see Mary R., a stout, healthy girl of fourteen summers, suffering from fecal impaction of the large bowel, complicated with an overloaded stomach, the result of having eaten a large number of rather hard apples.

The child was first seen in convulsions, for which she had received the usual course of antispasmodics, with morphine to relieve pain and apomorphine to produce emesis, with no result. I suggested the use of a tobacco enema, made by adding half a dram of good plug chewing-tobacco to half a pint of boiling water. Owing to the urgency of the case, this was cooled as rapidly as possible, and the entire quantity injected by means of a Davidson syringe with a long rectal tube. The enema was retained for about twenty minutes, when we had the satisfaction of seeing our patient under the pressure of a double evacuation, followed by immediate relief. The patient's recovery was uninterrupted.

CASE II.—I was called one morning at an early hour to see a strong and healthy laboring man, about sixty years old, with the following history: He had not had a free movement of the bowels for several days, and had been doing some hard lifting during the previous day; the bowels were tympanitic, with severe enteralgia, palpation being impossible on account of pain and tenderness. I gave him large doses of morphine with atropine hypodermatically and by the mouth, with copious warm-water and soap enemata, with no result.

I then administered an enema of tobacco—of a strength of one dram to a pint of boiling water, and allowed to cool to a proper temperature—by means of a Davidson syringe and a twenty-six-inch rectal tube introduced to its full length. The patient commenced to experience some relief from pain in fifteen minutes, and to suffer somewhat from nausea. In twenty minutes from the time the enema was given there was a copious fecal evacuation, with immediate relief, followed by a quiet sleep. No further attention was required, and the patient was able to be up and about on the following day.

Should I deem it expedient to use this method in the treatment of a delicate individual, I would fortify the patient against any undue depression that might follow the remedy by administering an ounce or two of good whiskey, with a half-dram of the aromatic spirits of ammonia, a few minutes prior to giving the enema.

Instead of the ordinary Davidson syringe, I would suggest the use of a long rubber tube attached to a suitable reservoir placed at a height ranging from four to ten feet.

CASE OF PREMATURE LABOR WITH OCCIPITAL HYDRENCEPHALOCELE.

BY J. W. WILLIAMS, A.M., M.D.,
OF PATERSON, N. J.

MRS. T., twenty-five years of age, a primipara, pregnant seven months, was admitted to the Paterson General Hospital January 14, 1890. True labor-pains, strong and frequent, had already begun. The position of the child could not be ascertained by abdominal palpation. The fetal heart-sounds could be indistinctly heard a little to the left of the umbilicus. The mother's abdomen was unusually large. Vaginal examination detected the os dilated and the membranes protruding in "glove-finger" form. The presentation was found to be a breech in the left sacro-anterior position. Although uterine contractions were forcible and frequent, but little progress was made at the end of four hours. The membranes were then ruptured, the amniotic fluid in excessive quantity coming away with a gush. About twenty minutes later the breech descended, and soon the body and arms were delivered; but here progress ended. The after-coming head resisted all efforts to deliver by traction, notwithstanding the fact that flexion of the head was complete and the size of the fetus small. Finally, after stronger traction, there was a sensation as though something had given way. The head was delivered suddenly, with a gush of fluid, and the cause of the obstruction was seen. This was a tumor arising from the occipital region and hanging down on the back of the child. The tumor was about the size of the child's head, although a large part of the fluid contents had escaped from a tear made at its base by efforts to deliver, and it is inferred that originally the tumor must have been at least twice the size. The tumor was covered by integument; hairy on its upper half. Examination showed the greater part of the occipital bone and two upper cervical vertebræ lacking. Through this gap had protruded the tumor-contents, which consisted of the cerebellum and greater part of the cerebrum and cerebro-spinal fluid. The remainder of the bones of the cranium and face were well

developed. The fetus was kept alive for half an hour by artificial respiration. It weighed eight hundred grams and was thirty-two centimeters in length. The mother recovered well.

ANTIPYRIN IN WHOOPING-COUGH.

BY AMOS SAWYER, M.D.,
OF HILLSBORO, ILL.

IN an epidemic of whooping-cough, three years ago, I depended entirely upon antipyrin, and effected a cure in from ten to twenty days, the shortest time being seven days, the average fourteen. My plan was to try to anticipate the paroxysm of cough by administering the remedy every three or four hours during the day, at the onset, lengthening the interval as the disease subsided.

In an obstetrical case, a two-year-old child, suffering with whooping-cough, slept in a bed of its own in the chamber with its mother. I advised the removal of the child before the baby was born, as well as that it be kept away from the other children until the time of danger had passed. The mother thought such precaution unnecessary, and the child remained in the room. Twelve days after birth the baby presented symptoms of whooping-cough, and for a few days it seemed that it would die from the violence of the paroxysms. After the administration of antipyrin in anticipation of the attacks, however, they gradually lessened in frequency and severity, until at the end of two weeks they ceased entirely.

I have administered many ounces of antipyrin to patients from a few days old to adult age without having witnessed an untoward symptom, possibly because, if it does not produce the desired antipyretic effect after the second dose (10 grains, repeated in an hour if necessary), I discontinue its use; or because I have been fortunate enough to escape coming in contact with a patient possessing an idiosyncrasy in this direction.

MEDICAL PROGRESS.

The Heredity of Hemophilia.—LIMBECK (*Prager med. Wochenschr.*, No. 40, 1891) presents the genealogy of a family for four generations in illustration of the hereditary transmission of hemophilia. The disease was first observed in the great-grandmother, who lived to be seventy-five years old. At sixty, severe epistaxis set in and continued at short intervals until death. The great-grandfather evinced no tendency to hemorrhage. These two gave birth to three children—two sons and a daughter. Neither of the sons, and none of the four children of the elder son showed any tendency to hemorrhage. The daughter, on the other hand, at puberty, began to suffer with profuse and sometimes protracted epistaxis. As a result of her marriage, fourteen children were born. Four of these died in infancy and childhood and a fifth at sixteen. To the epistaxis of the mother was added profuse post-partum hemorrhage, and she died at fifty after hemorrhage from the genitalia, mouth, and nose. The oldest child, a male, and his three sons presented no manifestations of hemophilia. In the second child, a female, profuse hemorrhage from nose and mouth had taken place since puberty. Her only child, a male, had since fourteen had severe and frequent epistaxis. A third child, a male, had had slight hemorrhages in youth but not in later life. His child was free from disease. The fourth child, a female, like her mother had bled from nose and mouth since her twelfth year. She bore four children. The first, a male, and the second, a female, suffered from occasional, severe epistaxis; the third, a male, had severe and frequent hemorrhages from nose and mouth; the fourth, a boy of five, presented no abnormal manifestations. The fifth child, a female, had been a profuse bleeder since her fifth year; she had aborted three times and had no living children. The sixth child, a male, had had frequent hemorrhages, particularly from the nose, since his eighth year; his son, a year old, had had none. The seventh child, a female of twenty-seven, and her son, had no hemorrhage. The eighth, ninth, and tenth children were males and bleeders. The eighth had presented decided symptoms of hemophilia since his seventh year and died at sixteen, it was said of cerebral hemorrhage. The ninth child was a moderate bleeder until his fourteenth year, but subsequently was free from hemorrhage. The tenth had had profuse hemorrhages between his sixth and eighth years, when they temporarily ceased, but after an interval of two years recurred.

Removal of a Fragment of Steel from the Retina by means of the Electro-magnet.—THOMPSON (*Lancet*, October 24, 1891) has recorded the case of a blacksmith who was struck in the left eye by a fragment of flying steel. Both eyes soon displayed evidences of irritation, with considerable impairment of vision in the left. Ophthalmoscopic examination of the injured eye revealed the presence of a foreign body in the retina, together with slight exudation and hemorrhage, and a number of fine, opaque striæ in the vitreous body. The patient being etherized, the original wound was reopened and the curved pole of an electro-magnet was introduced and passed through the vitreous in a direction corresponding to that apparently traversed by the foreign body. The second application was followed by the appearance of the bit of steel "in tow" of the magnet. The small bead of vitreous that presented was snipped off, the eye was antiseptically irrigated, and a compress was applied. In the course of a short time the manifestations of irritation subsided and vision become improved, though a slight patch of opacity remained upon the retina, and the field of vision was correspondingly limited.

Combined Pylorectomy and Gastro-jejunostomy.—JESSETT (*Lancet*, October 24, 1891) has reported the case of a married woman, thirty-eight years old, who had borne six children, but presenting no family history of carcinoma or tuberculosis. For more than a year there had been vomiting at irregular times, and there was constipation. Pain, emaciation, and debility soon followed. Some eight months previously to coming under observation, a few days after a twin-labor followed by puerperal fever, a small tumor was detected on the right side of the abdomen. A diagnosis of pyloric obstruction of a malignant character was arrived at, and pylorectomy in conjunction with gastro-jejunostomy, by means of bone plates, was performed. The course of the case subsequently to operation was most satisfactory.

The Medical News.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to The Medical News will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment. When necessary to elucidate the text, illustrations will be provided without cost to the author.

Address the Editor: GEO. M. GOULD, M.D.,
1004 Walnut Street,
Philadelphia.

Subscription Price, Including Postage in North America.

Per Annum, in Advance . . . . . $4.00.
Single Copies . . . . . 10 cents.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Philadelphia.

SATURDAY, NOVEMBER 28, 1891.

PHYSICIANS SHOULD DISPENSE THEIR OWN MEDICINES.

Because:

1. *Chemical and pharmaceutical science and art have reached such perfection that it is now possible and even convenient to do so.*

In former times, in order to get the physiological actions and therapeutical effects of a drug it was necessary to give large doses, the essential principle being mixed with large quantities of neutral or alien matters. The impossibility or inconvenience, therefore, of carrying with one an outfit of medicaments sufficient to meet any emergency that might arise, differentiated the professions of medicine and pharmacy, and created a dependence of the physician upon the druggist that at the present time, and under changed circumstances, is working injury to the medical profession. It is to-day possible to carry in one's vest-pocket a supply of concentrated alkaloids and extractives of all the chief articles of the modern materia medica amply large and sufficiently varied to cope with all ordinary cases of disease that one may be called to see. Pharmacological science has of late made wonderful progress, and the richness and diversity of the elegant preparations made by the best laboratories excite genuine surprise and praise. To hand the patient the day's supply of these marvellous little triturates, discs, pellets, tabloids, or alkaloids, is less trouble than to write a prescription.

2. *It saves the patient money and trouble.*

And why should we not desire to do this? To the vast majority of patients the question is one of great importance. The druggist's bill is doubtless small enough, but it is often unnecessary. Not only the very poor, but even those not poor, feel sufficiently the loss of time and labor incurred in the course of any illness; the worry and care are poignant enough without the unnecessary addition of the apothecary's charge. The interests of patient and doctor are closer than those of doctor and apothecary, and our solicitude for the patient may reasonably be extended to such pertinent things. The sacrifices of loved ones for their sick constitute one of the most pathetic of the many things that touch the heart of every sympathetic practitioner. It is but the simplest duty to spare them a useless addition to the burden.

The druggist must charge about the same for the filling of a prescription either for a small or large quantity of medicine. In acute diseases one kind of medicine is required for but a few doses, when a change is demanded. There is a rain of new prescriptions, much expense and trouble is caused the patient, and the accumulation of bottles of unused medicines produces malevolent suggestion and discontent. All this is different when the day's supply is given with the day's visit. The plan also adds but the slightest amount, or none at all, to the physician's expenses. These preparations are almost absurdly cheap. Even if no additional charge be made, the increased practice resulting would fully compensate the little and temporary increase of professional expense.

3. *The ordinary character finds it hard to pay for simple advice.*

The average person, and even many of the best of our patients, feel some resentment when called upon to pay for advice pure and simple. In matters non-professional everybody is so more than willing to give everybody else the article wholly gratis, that to many it seems like impertinence to ask payment even for the medical variety. The quack, with his unrivalled scent for the foibles of human nature, has profited by this fact, and even if he give only smells and oceanic dilutions of an essential principle, the medicine, or supposed medicine, is given—*with* the advice, and the patient is grateful for getting *something* for his money. Among

the little things that, as causes of professional success, we in our short-sightedness are prone to overlook, this little factor has doubtless been wondrously effective in biassing the minds of many patients for so-called homeopathy. Placebos and imagined therapeutics form the essential element of many a hoary and tattered medical joke, and the corresponding psychological fact must be well-rooted in human nature. It therefore obtains that even if no more worthy and weighty reason existed, one might gladly throw this innocent sop to Cerberus. But, happily, better reasons do exist.

4. *In emergency cases and in severe forms of acute disease time is saved and the disease more effectually withstood by the immediate administration of the needed remedy.*

Every practitioner knows that in many cases greater promptitude in the administration of the medicine would be a decided gain in the control of the disease. Doubtless many a critical stage has been passed in which life might have been saved had the needed drug been at hand and immediately given. The trip to the pharmacist and the *de novo* preparation of the compound by him (already prepared and in a hundred forms already present on the druggist's shelves!) waste valuable time. In country practice, especially, this is a very important consideration.

5. *The accidents of prescription-writing and of prescription-filling are lessened, while at the same time (with proper care and watchfulness over laboratory preparations) the efficacy and physiological effects of drugs are assured.*

It needs no mention of the self-evident fact that if prescriptions are not written, there will be no mistakes made in writing them, in reading them, or in compounding them. The frightful accidents almost daily happening, the sorrow, and the medico-legal misery consequent thereupon, would not exist. A physician would hardly make a blunder in giving the drug himself, and the possibility becomes almost *nil* when we recollect that the dose is parcelled out and labelled in the pharmaceutical workshop and with an accuracy unapproachable by the apothecary.

It would follow, that to have trustworthy assurance of standardization, solubility, etc., the medical profession should be able to certify to its members the preparations of certain manufacturers as reliable. At present there are a number of manufacturers whose products are beyond suspicion. A plan should be agreed upon by the two interested professions whereby the desired guarantee could be given, watchfulness secured, and the dangers of commercial avarice averted.

There would necessarily follow—and indeed, it should long since have been routine—that medical students should be instructed in the values and varieties of these preparations, and before graduation should become entirely familiar with them. The elder teaching of materia medica, the medieval pottering over botanical and laboratory trivialities must give way to civilized ways, and to the *knowledge of the use of finished products.* The pharmacologist and the chemist are noble allies and helpers, but they are not physicians, nor, if excelling in their work, have they time to be. Neither has the clinician the time to do their work. The professions are henceforth different. As to the drugs he uses, it is now no more requisite that a physician dig the roots and herbs, or execute the thousand chemical and pharmacological manipulative details required in the perfection of his preparations, than that as to his knives and forceps he should dig the iron, smelt and temper it, and learn the thousand technical details of the instrument-maker's art. With its infinite differentiation of function, civilization has rendered all this useless. The physician's task is to intelligently use the instruments (triturate, tablet, alkaloid, or surgical knife) furnished him by his friends and allies, the chemist, the pharmacologist, and the instrument-maker. If these shirk their duty there are speedy and effective ways of punishment.

And if commercialism is suspected of bribing the teacher, that too will come to a righteous ending.

6. *It will lessen the evils of hospital abuse, drug-store doctoring, the system of druggists' commissions to physicians, and of counter-prescribing.*

There can be no doubt that the wretched hospital-abuse—that encouraged parasite that is sucking the life-blood of his foolish host—is largely a product of this unnecessary exaggeration of the mechanics of treatment. Doctor and druggist are, in combination, "too much for" many poor souls that can so easily escape the charges of both by the debauching charity of their sentimental pauperizers. The young practitioner thus denied his legitimate *clientèle* by those who should be his helpers, may take a hint. He will secure the gratitude of his patients and increase their number by dispensing his own medicine.

The drug-store doctor can thus legitimize his

ways, and instead of turning his prescription over to his clerk to collect the fee by a double charge for the drug, he may charge for advice *with* medicine and not be ashamed to look at himself in the mirror.

"Division of the spoils" by druggist with doctor —more common, alas! than we like to know—would thus be checked, and probably the sponger of medical advice would get ashamed to pester the druggist and the soft-hearted physician.

It may perhaps be said that the plan is nowadays beneath the dignity of the aristocratically inclined modern physician. If that be the sole argument against it, the answer would be brief and pointed: Dignity to the dogs! The physician that in such matters thinks first of his dignity is a square peg in a round hole. He is out of touch both with his countrymen and with his fellow-practitioners.

It is by no means contended that the plan advocated can have an absolute and unexceptional realization. Judgment must modify all hard and fast rules. In cities where competent pharmacists and full supplies are close at hand, it may be preferable to continue the older method. But the city is a small part of the Country, and those desiring to adopt the plan suggested, may feel every warrant of good reason to justify their practice of it. It is both good morals and good medicine.

THE LESSON OF A MALPRACTICE SUIT.

The plaintiff in a suit for malpractice brought in the Philadelphia courts has been non-suited, and in order to bring out the moral of the story, we give some of its details:

On March 15, 1889, the plaintiff visited a market in West Philadelphia, and, accidentally stepping on a knife, the point was thrust through the tendo Achillis. She immediately summoned Dr. A. F. Chase, who, finding a narrow punctured wound with but little separation in the tendon, and no bleeding, carefully dressed the parts, with the foot extended so as to relax the gastrocnemius. Thinking that the case might get into the courts, Dr. Chase asked Dr. O. H. Allis to see the patient five days after the accident. The wound was then healed, with evidence of separation of the tendon of about a quarter of an inch.

The butcher before whose stall the accident happened was anxious to make all reasonable amends, offering to pay the woman for lost time and to meet the necessary expenses of the injury. This was not satisfactory, and suit was accordingly entered against him. Before the suit could be brought to trial he sold out his business and left for parts unknown.

The plaintiff then consulted her lawyer with reference to bringing suit against the market company. This, he assured her, would be useless, and, finding that suit was to be brought against the attending physician, the lawyer gave up the case.

About this time the plaintiff, desirous of getting outside medical testimony, engaged a carriage, was driven to a well-known hospital, was carried tenderly into the "out" surgical department, and, after the examination, was again carried tenderly back to her carriage, having, as she thought, gained some important medical testimony as to what would have been proper treatment of the original injury. She also engaged the hospital surgeon to attend her at her home. Unfortunately for her, but quite the reverse for the defence, it was observed that in the evening of the same day the plaintiff was seen to leave her home and walk to a neighbor's, apparently as if nothing had happened to her.

Fortified with additional medical testimony, counsel was again employed, and action brought against Dr. Chase in March, 1890. Witnesses were subpœnaed and every preparation made for the trial, but for some reason the case was continued. Again in April it was on the list, and again deferred, and finally, in October, 1891, the plaintiff was non-suited for non-appearance.

The point to be emphasized is one that occurs in nearly all suits for malpractice. Physicians hear and credit the statements of the plaintiff, and then freely state what should have been done at the time of the injury. Upon the testimony of the hospital surgeon the plaintiff felt she had a good expert witness, but when he learned the facts of the case, as presented by two competent medical witnesses, his remarks to the plaintiff were recognized as untrue and unjust, and their retraction would be necessary in open court. There is no doubt that the plaintiff learned that she could not depend on the surgeon of the hospital, and this fact, together with the difficulty she had experienced in getting another physician to serve her purpose, caused her to abandon the case.

It is to be regretted that medical men are so free to talk about cases of which they know nothing—

so free to mention their own successes in similar cases—so free to state what would have been the result had another course been pursued.

Had the butcher stood fire, there would have been no action against anyone else; but when both butcher and market company failed the plaintiff, then somebody else must be found that would not run away. The physician had then to suffer the annoyance of a suit, which, as in this case, though resulting in his favor, has always an annoying and even damaging effect.

DR. RHOADS'S METHOD OF LENGTHENING TENDONS, NERVE-TRUNKS, AND BONES.

IT has often happened that a discovery once made has been re-made by another, independently and at a later date. The classic example of this is the oft-quoted instance of DARWIN and WALLACE wholly unknown to each other, working out the same great theory of natural selection. In surgical procedures another illustration of the same fact has lately come to our notice. About three years ago Dr. J. NEELY RHOADS, of Philadelphia, hit upon the plan of lengthening contracted tendons by cutting transversely half through the tendon, then longitudinally to any desired extent, and finally finishing the division by cutting through the remaining half of the tendon on the side opposite that on which the original transverse incision was made, and at a point longitudinally removed from it. The desired lengthening of the tendon could thus be accurately determined and limited by allowing the severed longitudinal halves to slip on each other so far as wished, and these could then by sutures be fixed in position until healing took place. DR. RHOADS was prevented from performing this operation three years ago by his patient being suddenly seized with typhoid fever, and dying. The ingenious plan was explained to a number of surgeons at the time. DR. O. H. ALLIS at once adopted it as a commendable operative procedure, advised it to his classes at the Jefferson Medical College, and has a number of times successfully performed it.

Without knowledge of the above facts, on November 29, 1890, PROFESSOR W. W. KEEN, acting upon the suggestion of DR. WEIR MITCHELL, carried out the operation in a case of post-hemiplegic contraction of the flexors of the fingers.

The original plan of DR. RHOADS was not to limit the method to tenotomies, but he recommended, and still suggests, that it would be of equal service in lengthening nerve-trunks, and *especially* in lengthening bones, when, for instance, one leg is shorter than its fellow.

The method is so ingenious and of such possible usefulness that we desire to call especial attention to it, as also to do justice to the original discoverer.

It may be worth remarking that this method of operation may possibly be of service in strabismus operations, and would be a more accurate and a preferable method of performing "graduated tenotomy" of the external ocular muscles, if "graduated tenotomy" have any usefulness whatever.

When only a slight amount of lengthening is desired, the following modification of the method was also suggested by DR. RHOADS: Transverse incisions are made half way through and on opposite sides of the tendon, but not exactly opposite each other, leaving without complete division certain longitudinal fibers in the center to slip on each other, and thus gaining a slight addition to the entire length of the tendon.

CORRESPONDENCE.

CINCINNATI.

Advertising in the Newspapers; Quacks and Quackery; Prescribing Druggists; the Hospital Abuse; Diploma-mills; Cranks.

SELDOM does a ripple of excitemeut disturb the tranquillity of the staid old medical profession of Cincinnati. Everything goes as it comes, and little notice is taken of passing events—except by the daily papers. In this matter we are unfortunately becoming quite metropolitan. Few important surgical operations escape full description in the newspapers, and many quite trifling affairs occupy more space in their description than would be required to cover their *locus in quo*. The older men are displayed in the operations which they perform, and the young men who have not the operations appear in lengthy interviews upon diseases that, on occasion, they are eminently qualified to treat. Unfortunately, again, men worthy of emulation have been thus victimized by the press. One of our leading surgeons who positively and persistently refused to permit a reporter to witness an operation, and has always pursued this course, was maliciously and meanly attacked by one of those pests of journalism—a cheap evening paper.

One newspaper undertakes to tell the medical profession why they should advertise as do the "quacks." Well, it generally requires a lifetime for the average newspaper reporter—and the editor, too, if proprietary interests are concerned—to learn the distinction between an honest, humane physician and the blood-thirsty abortionist who so materially aids the worthy cause of debilitated journalism by cash contributions for squares and editorial comment. Hence the profession aforesaid cannot wonder at disinterested advice coming from such sources.

Owing to the ridiculously lax laws for the regulation of the practice of medicine in Ohio, this city has become the refuge—from adjoining States—of the "irregulars" of every description, and our profession complacently watches the sport. Quack follows quack, each remaining until his name and methods become familiar; then he silently steals away, or moves to another part of the city and begins business under another name. It is not probable that any effective legislation could be secured under present management. The retail druggists are far ahead of us in this regard. They not only regulate themselves, but dictate to the wholesale dealers, and would gladly assume the management of the entire medical profession of America. An effort was made a few months ago to render it unlawful for a physician to dispense his own remedies. Yet the vast majority of Cincinnati druggists prescribe indiscriminately and boldly. Quite a number of them also prepare and advertise their proprietary remedies—especially their sure cures for venereal diseases.

Fully 2000 persons are treated daily, free of charge, in our hospitals and free dispensaries. Yet of all this clinical richness, less than a tenth is in any manner utilized for the good of humanity, if we except that small but important part of humanity directly connected with the institutions referred to. There are still a few practitioners who have not become identified with hospitals or dispensaries, hence it is difficult to predict the future of clinical medicine; but to a casual observer it appears that we have a surfeit of medical charity.

Diploma-mills are just now attracting attention. The proverbial disagreement between knaves revealed at least one source of bogus diplomas, but it is doubtful whether any real good will come from the exposure. The title of the mythical institution was the Medical University of Ohio. Under this dignified name it holds a charter from the State. Proceedings are now pending to revoke the charter; but this measure will probably result in greater secrecy or a change of name. No punishment short of imprisonment will arrest the operations of these swindlers.

We have other chartered institutions whose standing is questioned. The American Eclectic College is not recognized by the Illinois State Board of Health. The College of Vitapathy is an institution which licenses its graduates to practice medicine, solemnize marriage, and otherwise monopolize the rights of the learned professions. Christian scientists—the so-called metaphysicians—have their victims, and there is an anomalous sect whose goddess is a woman alleged to impersonate the Saviour. She receives money and prayers, and cures by the laying-on of hands. Other concerns are believed to exist that either publish or act as agents for bogus diplomas, but they are fairly secure under the charters that they hold. Wisely did Plautus exclaim: "Little do you know what a gloriously uncertain thing the law is."

THE TRANSMISSION FROM PERSON TO PERSON OF DERMATITIS DUE TO RHUS TOXICODENDRON.

To the Editor of The Medical News,

Sir: For many years I was unaffected by the rhus poison, and assisted folks to rid their gardens of that pest by pulling the vine up root and branch, but in 1880 I was infected by the *rhus radicans* whilst clearing out my cemetery lot. The points I desire to note are these:

1. After leaving the cemetery, on my way home, having washed my hands thoroughly, I dressed the arm of a lady having a Colles fracture, and two days thereafter the eruption appeared on my arms and hands. The next day I saw the patient, *and she had the rash out fully*. A gynecological case seen on the day of my inoculation showed the same effect three days afterward, yet neither of these women could have gotten the trouble other than through myself.

2. Friction of the skin through the clothing at points far from the affected localities developed the rash soon thereafter, showing the disorder to be systemic as well as local. This I repeatedly found true.

3. Treatment prior to the eruption showing itself in those known to have been exposed does not appear to delay or prevent the attack.

4. I have found freshly home-made lime-water the best local application, and fluid extract of jaborandi and iron the preferable internal remedies. The jaborandi I consider a specific in this trouble.

In my own case, as a result of innumerable experiments, I found galvanism the best agent for relieving the excessive itching, but very great care must, of course, be taken in applying electrodes, by thorough washing and the use of absorbent cotton (to be thrown away) to prevent transfer to other victims.

Of all the *anacardiaceæ*, the *rhus pumilum* is the worst in its effect as a poison; the *rhus radicans* is the next, and the *rhus toxicodendron* the mildest, the *rhus venenata* being so infrequent a toxic agent as to merit little notice. No matter how severe the infection about the face, I never knew the eye to be injured, even when the lids were swollen to an immense size.

I called attention to some of these facts in a short paper in the *Philadelphia Medical Times*, in September, 1880.

Very truly yours,

Wm. R. D. Blackwood, M.D.

246 North Twentieth Street.

[We have received quite a number of letters from practitioners describing numerous instances of the transmission from person to person of the poison in question, but as the cases are mostly repetitions of the fact, with slightly varying circumstances, it is not thought necessary to publish a number of the letters. The Medical News, however, would express its recognition of the courtesies of its correspondents. Dr. Cantrell's report has served to bring out and emphasize a new or somewhat unknown clinical fact of considerable importance.—Ed.]

WASHINGTON AS A MEETING-PLACE.

To the Editor of The Medical News,

Sir: As a Kentuckian, I am supposed to carry on my journey a corkscrew and such other agencies and antidotes as shall best serve to protect me against the dangerous effects of water-drinking. As a Southerner I am presumably a semi-salamander, while my hot-bread-three-times-a-day dietetics (old Virginny style) will, I am sure, shock the esthetic table-habits of the Northern-*bred*. Since coming home from the Congress, sick, I

have read everything you have published in regard to the supposed cause or causes of the diarrhea that so many of us had. I am surprised at the opinion that the fault lay in the food. Men who revel in a high-game club diet and the like at home, went down under plain cooking there, while, irrespective of instances, it may be suggested to those who seem to have forgotten, that if bacteriology teaches anything, it is the efficacy of cooking as a sterilizing procedure. The afternoon of the second day I walked with several others from the Grand Army Hall to the Shoreham. We were hardly able, from prostration and a sense of suffocation, to make the final diagonal crossing at the hotel-corner. On interrogating the thermometer in the drug-store, it was found to register but a paltry 86°; this to one accustomed to live and labor in a summer atmosphere of 98° seemed inexplicable, but a question promptly answered by the single word *humidity* cleared the matter at once. In my opinion, humid, hot air from the Potomac flats, bearing disease-germs in its relaxing and prostrating blasts, despite studied abstemiousness on the one hand or vinous inclinations on the other, seems to have been the cause of the trouble. Speaking of eating and drinking at the Congress, Dr. Battey Tuke said to me: "I have attended all of the great Congresses and Associations of the world, and I have never seen so little junketing and so much work. I have learned more here than at any meeting I have ever attended."

E. R. PALMER.

LOUISVILLE, KY.

"THE PROTECTIVE" IN ANTISEPTIC DRESSINGS.

To the Editor of THE MEDICAL NEWS,

SIR: Dr. Benjamin's estimate of the value of the protective in wound-dressings, published in THE MEDICAL NEWS, October 31st, was interesting.

By those who favor its use it is said that this portion of the dressing assists, through its adhesive quality, in keeping the fresh edges of the wound approximated; and that by the same quality, when thoroughly sterilized, it excludes germs that necessarily persist in the deeper portion of the surrounding field from finding an entrance to the wound itself.

That such a result is obtained is very questionable, and that the protective does shut in the slight, unavoidable exudate and furnish an excellent culture-medium is equally unquestionable.

I am convinced that some form of protective is useful in addition to the ordinary dry, antiseptic, absorbent dressing, and for some years I have employed one that is familiar to surgeons in this vicinity as well as to others of your readers, I presume.

A single narrow strip of gauze—bichloride, iodoform, or what you please—is laid over the incision, giving a border of half an inch about the cut and stitches; over this is laid a thin strip of sterilized, absorbent cotton, with its border, in turn, one inch outside of the border of the gauze. The edges of the cotton are thoroughly pasted down with contractile collodion, the middle being left dry for the escape of exudate. By this simple contrivance the first purpose of the more familiar protective is admirably served—that is, the wound edges are well supported. Whatever virtue there may be in the tissue protective for excluding germs is certainly attained by the collodion dressing, with the advantage that the medium about the wound is less rich in fresh exudate.

The outside dressing of gauze and cotton is applied in the usual manner. Yours,

JAMES G. MUMFORD, M.D.

197 BEACON STREET, BOSTON.

HYPODERMATIC INJECTIONS IN DIPHTHERIA.

To the Editor of THE MEDICAL NEWS,

SIR: THE MEDICAL NEWS of some weeks back gave a report of Professor Seibert's treatment of diphtheria by injections of aqua chlori beneath the diphtheritic membrane. Some description was given of the peculiar syringe used.

I wish to report a use I have made, with considerable success, of the Seibert syringe, to wit: The employment of this syringe for the injection of strychninæ sulphas into the pharyngeal muscles in post-diphtheritic paralysis. Ten minims of a one-grain-to-the-ounce aqueous solution were injected daily.

The hypodermatic use of strychnine in this form of paralysis is, of course, a common measure; but the peculiar adaptability of the *Seibert syringe* for this purpose, and my own experience with it, prompt me to send this communication. Respectfully,

WM. S. BARKER, M.D.

ST. LOUIS, MO.

TOPICAL APPLICATIONS IN DIPHTHERIA.

To the Editor of THE MEDICAL NEWS,

SIR: I have found the following to be an efficient application in the treatment of diphtheria. It can be employed in all stages of the disease, without danger to the patient. It should be applied often and thoroughly, by means of a brush or cotton swab, until the diseased membrane entirely disappears. In connection with this remedy I give as much brandy as the patient will bear, and such other remedies as may be indicated.

℞.—Acidi borici	ʒj.
Acidi lactici	fʒj.
Glycerini	fʒjss.
Aquæ dest.	fʒijss.
Liq. ferri subsulph. . . .	fʒjss.—M.

This solution may be used in full strength or diluted with water, as each case may require.

Yours truly, GEORGE W. PECK, M.D.

OMAHA, NEB.

IDIOSYNCRASY.

To the Editor of THE MEDICAL NEWS,

SIR: An editorial in THE MEDICAL NEWS of November 14th, entitled "Idiosyncrasy," recalls to my mind an interesting case. In the spring of 1890 a young lady, after eating a fried codfish-cake, was seized with cholera morbus, extreme dyspnea, and an intolerable itching of the whole cutaneous surface. Some six hours afterward a general urticaria developed. The symptoms were intense for two days and mild for three days more. The mother said that some years before, the daughter, during convalescence from one of the diseases of childhood, had experienced a similar attack, but of milder degree,

after eating codfish-steak. Three weeks after the attack in which I saw the girl the mere odor of cooking fish induced a mild recurrence of the attack. Three months later she again became ill from smelling fish, since which time (now over a year) she has had no similar trouble.

Willoughby I. Wood.

Brooklyn, N. Y., Nov. 16, 1891.

REVIEWS.

A Manual of Hypodermatic Medication: the Treatment of Disease by the Hypodermatic or Subcutaneous Method. By Roberts Bartholow, A.M., M.D., LL.D., Emeritus Professor of Materia Medica, General Therapeutics, and Hygiene in the Jefferson Medical College of Philadelphia; Honorary Fellow of the Royal Society of Edinburgh; Honorary Member of the Société Médico-Pratique de Paris; Fellow of the College of Physicians of Philadelphia, etc.; author of a Treatise on the Practice of Medicine; of a Treatise on Materia Medica and Therapeutics; of a Manual of Medical Electricity, etc. Fifth edition, enlarged and revised. Pp. 529. Philadelphia: J. B. Lippincott Company, 1891.

The many pupils of Professor Bartholow, that have been guided by his teachings through the difficulties of medical practice will be gratified to learn that, since laying aside the cares of professorial work, he has been devoting his energies to a careful revision of his various works, so as to give to the profession the results of his careful scientific observations, his mature reflections and judgments. The present edition, the fifth, of his work upon hypodermatic medication is the first of the series to appear. In its enlarged and revised form it will be cordially welcomed by those that are familiar with the methods of hypodermatic treatment advocated in previous editions, since it contains a complete but well-digested summary of the existing state of knowledge in this department of therapeutics. There is no similar work that covers the same ground so thoroughly or so satisfactorily.

As stated in the preface, the book has not only been revised, but has also been enlarged by the addition of nearly two hundred pages of new material. All of the modern drugs that have been employed hypodermatically have received more or less consideration in proportion as they have been found therapeutically valuable by thoughtful clinicians. In recasting this edition, Professor Bartholow has arranged the remedies in accordance with the scientific classification adopted by him in his work on materia medica and therapeutics, and which is based upon their physiological actions; while objections may be urged against this classification, it is, nevertheless, on the whole, the best that has as yet been suggested, and if carefully studied will afford a clear insight into the true actions of drugs, their antagonisms and therapeutic uses.

Some thirty pages are devoted to a sketch of the history of hypodermatic medication; to a consideration of the methods employed in the administration of a remedy, to its local and systemic effects, to the characters of syringes and needles—small details in one sense, and yet upon their due appreciation depends the success largely of this form of treatment. Under each heading will be found the best methods of preparing drugs, and the various formulæ which have been found most efficacious, not only by the author but by clinicians throughout the world. The physiological effects which follow the injection are stated in a clear, concise, and thorough manner. The physiological antagonisms of drugs, a subject that Professor Bartholow has particularly elucidated, is explicitly pointed out. The therapeutical indications for the employment of the remedies by the needle are numerous and their value attested by the author's own vast experience and by references to the published experiences of other thoughtful observers.

As an illustration of the compleness of this edition, it may be stated that 20 pages are devoted to a consideration of mercury and its salts; 17 to iodine; 22 to pilocarpine; 13 to antipyrin; 71 to morphine; 73 to atropine and its combinations with morphine, physostigmine, and pilocarpine; 10 to hyoscyamine and hyoscine. It is unnecessary to mention the space devoted to the remainder of the drugs; suffice it to say that each receives careful consideration. Altogether it is the best work in the English language pertaining to this subject, and one that should be in the possession of every physician who wishes to be abreast of modern therapeutics.

Artificial Anesthesia and Anesthetics. By De Forest Willard, A.M., M.D., Ph.D., Clinical Professor of Orthopedic Surgery in the University of Pennsylvania, etc., and Lewis H. Adler, Jr., M.D., Instructor in Rectal Diseases, Philadelphia Polyclinic and College for Graduates in Medicine. 8vo., pp. vi, 144. The Physician's Leisure Library. Detroit: George S. Davis, 1891.

This little volume is a creditable *résumé* of our knowledge on the subjects with which it sets out to deal. Anesthesia and anesthetics are considered from all points of view and in all their various phases in a clear, concise, and orderly manner. Not a little value attaches to the work from the fact that the conclusions reached are based upon a not inconsiderable experience on the part of one or both of the authors. As is natural, those methods are commended as the best with which the operator has had the largest experience. The skill acquired by repeated manipulation makes the more familiar procedure the safer. The fact implied in these statements is exemplified in the selection of either ether or chloroform as the anesthetic. Of ether it is said that "it is the safest known agent for the production of prolonged narcosis." The conclusion of the Hyderabad Commission that "chloroform may be given in any case requiring an operation with perfect ease and absolute safety, so as to do good without the risk of evil," is held to be "a somewhat sweeping assertion." The fact that we wish to emphasize is that either chloroform or ether is comparatively safe as an anesthetic in the hands of one who is skilled in the use of the one or the other, and that the chances are that the surgeon will use that with which, by accident or association, he has become most familiar.

The book is well printed, the typographical errors few and unimportant. It can be profitably read by all that are interested in the subjects of anesthesia and anesthetics.

Minor Surgery and Bandaging, including the Treatment of Fractures and Dislocations, Tracheotomy, Intubation of the Larynx, Ligation of Arteries and Amputations. By Henry R. Wharton, M.D. Philadelphia: Lea Brothers & Co., 1891.

Dr. Wharton has written a book especially designed for students and younger practitioners, superior in many respects to others on this subject. The portions of it devoted to bandaging and fracture-dressing are particularly good. Full and accurate verbal descriptions of the mode of applying all the important bandages, and of the best modern methods of treating and dressing fractures and dislocations, are supplemented and rendered still more valuable by a number of excellent illustrations, most of them new. These have been photographed from life, and, with the improved methods now employed for reproducing such figures in a form suitable for book publication, they combine the advantages of clearness of outline and accuracy in portraying the various turns of the bandages they represent. Thus the methods of application of the various dressings are rendered more easy of comprehension than by verbal description.

The part of the work devoted to a description of the different substances and materials used in antiseptic dressings and operations and the mode of their preparation seems also excellent.

Among the descriptions of the various procedures employed in minor surgery, we hope, in a second edition, to see more special reference made to the treatment of felon, onychia, etc. A few words upon the drawing of teeth might also find a useful place in the book.

A complete index of fourteen pages, containing over 700 terms, brings the size of the book up to 497 pages.

A Manual of Practical Obstetrics. By Edward P. Davis, A.M., M.D., Clinical Lecturer on Obstetrics in the Jefferson Medical College; Professor of Obstetrics and Diseases of Children in the Philadelphia Polyclinic; Visiting Obstetrician to the Philadelphia Hospital; Physician to the Children's Department of the Howard Hospital; Member of the American Gynecological Association. With one hundred and forty illustrations, two of which are colored. 8vo., pp. 298. Philadelphia: P. Blakiston, Son & Co., 1891.

Books upon obstetrics have so largely multiplied that one may reasonably doubt if any immediate necessity existed for additions to the number. Good books, however, are always welcome, and will be given cordial reception. In this class belongs the manual of Dr. Davis, of which it is to be said that, though concise, it is clear in expression and accurate in statement. Within narrow limits a great range of subjects has been discussed with admirable skill and precision. The text makes easy and agreeable reading. The utility of the work is greatly enhanced by a large number of excellent illustrations. The descriptions of some of the plates might advantageously have been inserted. By an apparent inadvertence the list of illustrations is not paged; it would be well if the list of plates were also paged. The book may be cordially recommended to those who do not desire to use the larger and more voluminous works on obstetrics.

Handbook of Materia Medica, Pharmacy, and Therapeutics, Including the Physiological Action of Drugs, the Special Therapeutics of Disease, Official and Practical Pharmacy, and Minute Directions for Prescription-writing. By Samuel O. L. Potter, A.M., M.D. (Jefferson), M.R.C.P. (Lond.), Professor of the Theory and Practice of Medicine in the Cooper Medical College of San Francisco, etc. Third edition, revised. Philadelphia: P. Blakiston, Son & Co., 1891.

This, the third revised edition of Dr. Potter's most praiseworthy work, is a compendious compilation of the subjects with which it has to deal, arranged in a convenient manner and provided with a complete index that makes reference easy. The articles of the Materia Medica are arranged alphabetically, the pharmacology, physiological action, and therapeutical application of each being concisely given. A section is devoted to pharmacy and to the art of writing prescriptions. The section on Special Therapeutics comprises a list of clinical conditions alphabetically arranged, with the remedies recommended for each. The appendix contains a good deal of useful information on a wide range of subjects.

The work should prove useful as an aid in the study of a subject that is at best not easily comprehended.

Essentials of Bacteriology. By M. V. Ball, M.D, Phiadelphia: W. B. Saunders, 1891.

We can cheerfully recommend this little volume as containing an excellent condensation of recent bacteriological teachings, presented in a lucid style. The faults of the work are minor, and pertain principally to the arrangement. One objection we feel we should note: The method of drying cover-glass preparations. Thorough air-drying is of such importance in the proper homogenization of the matter spread on the glass, that the neglect of it causes more failures in staining than any other error, and it is bad advice to suggest drying over a Bunsen flame, even though the student be cautioned against excessive heat.

The amount of material condensed in this little book is so great and so accurate are the formulæ and methods, that it will doubtless be found useful as a laboratory hand-book.

Physicians' Ready Reference Account Book. Arranged by Gideon C. Segur, M.D. Pp. 300. Hartford, Conn.: The Plimpton Manufacturing Co., 1891.

This book is admirably adapted to take the place both of the visiting list and the cumbersome ledger of the physician. A single line on any page is sufficient to convey the desired information as to charges, credits, and balances for one month; charges and credits being entered in black and red ink respectively. Space is economized, as it is possible, if desired, to enter several accounts on the same pages.

The last fifty pages are devoted to short accounts, an extra column being here added for previous charges. In these accounts reference is facilitated by indexing the page and line. The book is, in short, as its name implies, a ready reference account book, the plan of keeping the accounts being of such a simple character

that a knowledge of bookkeeping is unnecessary. It is of convenient size and bound in half morocco. The price, $3.50, is moderate.

Obstetrical Nursing. A Handbook of Obstetrical Nursing for Nurses, Students, and Mothers. (Comprising the Course of Instruction in Obstetrical Nursing given to the Pupils of the Training School for Nurses connected with the Woman's Hospital of Philadelphia.) By Anna M. Fullerton, M.D., Demonstrator of Obstetrics in the Woman's College of Pennsylvania; Physician-in-Charge and Obstetrician and Gynecologist to the Woman's Hospital, etc. Second edition, revised. Philadelphia: P. Blakiston, Son & Co., 1891.

The simplicity of style and direct method of teaching are sufficient in themselves to recommend this little book. The matter contained in it necessarily presents little that is new, and the arrangement of the book differs in no respect from that of similar handbooks.

The chapter, however, on the Care of the Newborn Infant is clearly, as the writer states in her preface, "up to the present standard of our knowledge." This chapter is carefully arranged, and the tables descriptive of the analysis of human milk, the rules of feeding, and the various formulæ for the preparation of artificial food are of great value for their clearness and the opportunity they offer for comparison.

In the preface to the second edition the writer cites the usefulness to the physician, the nurse, and the patient, of her work. In attempting to meet such varied wants she has undertaken a serious task, but a careful study of the succeeding pages will convince the reader of the success which has attended her efforts in this respect.

The careful training and the unusual advantages for observation in this branch, and the natural insight into the requisites of good nursing on the part of the writer, contribute to make this the standard text-book on this subject.

NEWS ITEMS.

Insanity, Blindness, and Deaf-Mutism in Vienna.—At the end of 1890 a census was taken of the population of the Austrian capital, which showed that it contained 1,380,917 inhabitants, being an increase of rather more than 23 per cent. as compared with the enumeration made ten years before. The proportion of the sexes was 51.63 per cent. of females to 48.37 per cent. of males. The number of persons suffering from mental or physical infirmity was 3964, of whom 983, or 24.8 per cent., were blind; 980, or 24.7 per cent., were deaf and dumb; 1627, or 41.04 per cent., were idiots or insane; and 374, or 9.44 per cent., were cretins. Of the whole number, 53.13 per cent. were males, and 46.87 per cent. were females. The excess of males as compared with females, however, holds good only as regards cases of deaf-mutism, insanity, and idiocy; the cases of blindness are equally distributed between the sexes, and as regards cretinism, the fair sex leads easily, the respective percentages being 39.3 males to 60.7 females. On comparing these figures with those of the census of 1880, it will be seen that while blindness has diminished by nearly 10 per cent., and deaf-mutism has remained stationary, insanity and cretinism have increased by 32 per cent. This increase is greater in the female sex than in the male, in the proportion of 43.02 to 23.2 per cent. Of the 983 blind persons, only 21, or 6 per cent., were born blind; the causes of the condition are said to have been blennorrhea neonatorum (in 14 cases), smallpox (in 11), other affections (in 295), and injury (in 17). Of 381 deaf-mutes not inmates of public institutions, 127, or 33.3 per cent., became deaf and dumb after birth. Of the cretins, 63.4 per cent. are between ten and thirty years of age, and 31 per cent. can do ordinary household work.—*British Medical Journal*, August 29, 1891.

Mortality According to Occupation.—At the recent Congress of Hygiene and Demography, Mr. Ogle presented statistics as to the comparative mortality among those between twenty-five and sixty-five years old engaged in the various occupations in England. The death-rate among clergymen being the least, this was taken as a standard of comparison. The following table presents the comparative mortality:

Clergymen	100	Wool-workers	186
Gardeners	108	Armorers	186
Farmers	114	Tailors	189
Husbandmen	126	Hatters	192
Papermakers	129	Printers	193
Grocers	139	Cotton-workers	196
Fishermen	143	Clerks	199
Cabinetmakers	148	Physicians	202
Lawyers	152	Quarrymen	202
Brushmakers	152	Bookbinders	210
Mechanics	155	Butchers	211
Tradesmen	158	Glassmakers	214
Woollen-drapers	159	Plumbers, painters, etc.,	216
Miners	160	Cutlers	229
Shoemakers	166	Brewers	245
Commercial travellers	171	Omnibus-drivers	267
Bakers	172	Wine-merchants	274
Millers	172	Bass singers	300
Upholsterers	173	Potters	314
Masons	174	Miners	331
Smiths	175	Hotel-waiters	397
Laborers	185		

Tuberculosis in German Prisons.—Cornet (*Zeitschrift für Hygiene*, x, 1891) has estimated that, in the past fifteen years, 45.82 per cent. of all deaths among males, and 49.33 per cent. among females, in prisons, were due to tuberculous disease. Below the age of twenty there was no material difference between the death-rate from tuberculosis among prisoners and that among the ordinary population; but between twenty and forty the death-rate was five times as high among prisoners as among the general population. Some of this excess is attributable to insufficient exercise and ventilation, and to want of variety in food. Another cause lies in the probable infection of cells by tubercle bacilli, insufficient care in disinfection being observed. In a considerable proportion of cases of tuberculosis in prisons the disease had existed prior to the incarceration, as is shown by the number of deaths from tuberculosis during the first few months of imprisonment.—*British Medical Journal*, October 24, 1891.

Vital Statistics.—According to the *Financial and Insurance Chronicle*, the yearly number of deaths throughout the world may be estimated as thirty-three million. Upon this estimate, there would be 90,410 deaths per day, 3767 per hour, and 62 per minute. The average duration of life is computed as thirty-eight years. A fourth of mankind dies before seven; a half before or at seventeen. One person in ten thousand lives to be a hundred years old; one in five hundred to be ninety; one in one hundred to be sixty. The life of the married is longer than that of the unmarried. Of a thousand persons that have lived to be ninety years old, forty-three were engaged in religious or political pursuits; forty in agricultural pursuits; thirty-three were artisans; thirty-two soldiers; twenty-nine lawyers or engineers; twenty-seven professors, and twenty-four physicians.

The Philadelphia Polyclinic and College for Graduates in Medicine has arranged a course of evening lectures, to be given by the members of the teaching corps on Tuesday and Friday evenings of each week, at eight o'clock, in the new Polyclinic Hospital, Lombard Street, above Eighteenth Street: Nov. 24, Dr. Edward Jackson, The Shadow Test; Nov. 27, Dr. B. Alexander Randall, Ear Diseases in General Practice; Dec. 1, Dr. S. D. Risley, The Diseases of the Choroidal Tract; Dec. 4, Dr. John B. Deaver, The Operative Treatment of Head Injuries; Dec. 8, Dr. Henry Leffmann, Recognition of Albumose and Peptone in Urine; Dec. 11, Dr. Edward P. Davis, The Use of the Forceps; Dec. 15, Dr. Henry Leffmann, Determination of Sugar and Urea in Urine; Dec. 18, Dr. S. D. Risley, The Diseases of the Choroidal Tract; Dec. 22, Dr. John B. Roberts, Fractures of the Elbow; Jan. 5, Dr. J. Henry C. Simes, Syphilis; Jan. 8, Dr. Lewis H. Adler, Jr., The Physical Exploration of the Rectum; Jan. 12, Dr. Arthur Van Harlingen, The Contagious Diseases of the Skin—Their Diagnosis and Treatment; Jan. 15, Dr. John B. Deaver, The Radical Cure of Hernia—Umbilical, Inguinal, and Femoral; Jan. 19, Dr. J. Henry C. Simes, Syphilis; Jan. 22, Dr. H. Augustus Wilson, The Mechanism of the Normal Foot with Reference to the Correction of Deformities; Jan. 26, Dr. Arthur Van Harlingen, The Antiseptic Treatment of Skin Diseases; Jan. 29, Dr. Lewis H. Adler, Jr., Congenital Malformations of the Rectum and Anus; Feb. 2, Dr. E. P. Davis, The Treatment of Delayed Labor.

Department of Midwifery of the New York Post-Graduate Medical School.—Mrs. C. P. Huntington has given the directors of the Post-Graduate Medical School $2000, a sum sufficient to defray the expenses of the midwifery department for one year. Professor von Ramdohr will have charge of the department, at No. 543 East Thirteenth Street, where instruction in obstetrics will be given to graduates in medicine only.

Nothnagel, of Vienna, recently celebrated his fiftieth birthday. A number of his pupils, including Rosenbach, v. Jaksch, Bamberger, and Kogerer, presented him with an album containing their photographs.

Professor v. Hippel was recently awarded the Welz Prize for his work on *A New Method of Transplantation of the Cornea*.

New York Pasteur Institute.—During the first six months of the second year of its existence (February 18, 1891 to August 18, 1891), 415 persons, bitten by dogs, cats, and other animals, applied at the New York Pasteur Institute for treatment.

In the case of 345 of these persons, it was demonstrated that the animals attacking them were not mad. Consequently the patients were sent back after having had their wounds attended to during the proper length of time. In 70 cases the anti-hydrophobia treatment was applied, hydrophobia of the animals inflicting bites having been evidenced clinically, or by inoculation at the laboratory, and in many cases by the death of some other persons or animals bitten by the same dogs.

Indigents have been treated free of charge.

In but one case did death occur after the treatment had been carried out.

The Vision of Sailors.—The city of Lübeck has adopted the practice of the city of Hamburg, of systematically testing the eyesight of sailors, especially as regards color-vision.

The German Dermatological Association will hold its next congress in September, 1892, at Vienna, under the chairmanship of Kaposi, in conjunction with the Second International Dermatological Congress.

Professor S. Exner has been made Professor of Physiology in the University of Vienna.

Dr. Julius Dreschfeld. who for ten years has been Professor of Pathology in Owens College, London, has been nominated for the Professorship of Medicine, to succeed Dr. Morgan, who has resigned.

Professor Gustav Edlefsen has resigned the chair of Internal Medicine in the University of Kiel, to take up his residence at Hamburg.

Dr. J. West Roosevelt, M.D., has been elected Professor of Clinical Medicine in the New York Post-Graduate Medical School and Hospital.

Professor R. v. Mosetig recently assumed direction of the surgical department of the Vienna General Hospital.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING NOVEMBER 21, 1891.

WOOLVERTON, THEORON, *Medical Inspector*.—Placed on the Retired List, November 13, 1891.

BRYANT, P. H., *Assistant Surgeon*.—Detached from Coast-survey Steamer "Gedney," and wait orders.

JONES, W. H., *Surgeon*.—Ordered to examination preliminary to promotion.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment, provided that the request for reprints be noted by the author at the top of the manuscript. When necessary to elucidate the text, illustrations will be provided without cost to the author.

ORIGINAL ARTICLES.

THE RADICAL TREATMENT OF UTERINE CANCER.

BY WILLIAM GOODELL, M.D.,
PROFESSOR OF GYNECOLOGY IN THE UNIVERSITY OF PENNSYLVANIA.

IN uterine cancer, if the vagina is not implicated, if the disease has not travelled along into the broad ligaments, and if the womb has not been fixed by adhesions, the immediate and remote success attending the operation of the removal of the womb is an extremely satisfactory one. The averages of immediate and permanent recovery compete most successfully with those of the excision of the breast for cancer. Thus, of 311 cases of vaginal hysterectomy performed up to the end of 1886, compiled by A. Martin, 47 died from the operation, giving a percentage of 15.1 per cent. Individual operators have done better than this, Leopold having lost but 4 of 80 vaginal hysterectomies, and Staude 1 of 22. On the other hand, of 778 cases of excision of the breast collected by Koester, the immediate mortality reached 15.6 per cent.

These figures, however, do not afford a basis of legitimate comparison between the immediate success of the two operations, because vaginal hysterectomy is a young operation, and every known case of extirpation of the womb for cancer is given. It therefore includes the earliest operations, performed long before the technique had been improved; whereas the operation for the removal of the breast has been accepted from time immemorial, and its technique has been long perfected. As regards permanent success, cancer of the breast is discovered earlier and is therefore operated on earlier, while cancer of the womb is rarely discovered until it has so far advanced as to have insidiously implicated contiguous and continuous structures. Even when it is discovered, being seated in an unseen organ, its dangers are not realized, and operative interference is liable to be postponed. Hence one would infer a larger measure of permanent success in mammary cancer. Yet, from personal statements lately made to me by several German operators that have become more expert, and who are now more careful in the selection of their cases, I am thoroughly convinced that the removal of the uterus *per vaginam* for cancer far surpasses in its remote, or permanent, success not only all other operations for cancer of the womb, but also all operations for cancer in other parts of the body.

Nor need we wonder at this success, because the lip, breast, penis, and rectum, which are the favorite sites of cancer, are integral parts and parcels of the body, while the womb is to the body only an appendage, which is merely suspended by stays and guys, and those of a different material.

This opinion is substantiated by the remarkable statistics of the Dresden Klinik brought up to date (*Medical and Surgical Reporter*, November 21, 1891, p. 834; from *Archiv für Gynäkologie*, Band xl, Heft 2). In these Leisse presents a tabulated statement of the histories of all of the patients, so far as they could be obtained. These histories are compiled with great care. Of 80 patients that were heard from upwards of two years after the operation, 56.25 per cent. were still living. As 8 of the deaths were not due to a recurrence of the disease, the actual mortality was only 17.8 per cent. Thirty-seven of the 45 surviving patients were examined at the klinik, so that there was no question as to their local condition; and in the other cases reports were received from competent physicians. The following are the facts: Of 80 patients examined over two years after the operation, 45 were free from recurrence; 58.6 per cent. (of 58 patients examined) were well after three years; 59.5 per cent. (of 42) after four years; 60 per cent. (of 30) after five years; 66.6 per cent. (of 9) after six years; and the 2 patients that had survived the operation seven years were perfectly well. The best showing, however, is by Leopold, who states that out of 76 of his cases remaining under observation after recovery, 72 were still well, without recurrence of the disease, from one to five and a half years after the operation.

Undoubtedly the general consent of gynecologists has fixed upon the vagina as the best channel through which the womb should be extirpated, whether for cancer, for incurable prolapse, or for fibroid tumor, provided the womb is not unduly enlarged—that is to say, provided the womb is small enough to be delivered through the vagina and vulva. But the same unanimity does not exist with regard to the technique of the operation.

Some surgeons, at the head of whom stand Péan and Richelot, secure the broad ligaments, either in sections by several catch-forceps, or, as a whole, by a single clamp on either side. Many, perhaps the majority of American gynecologists, have adopted

this mode of procedure, and there is hardly one, not excluding myself, who has not invented a special form of clamp. This is usually a more rapid mode of operating, and the clamps are kept on only from forty-eight hours to three days; but it has its objections. First, the ends of the clamps, or the beaks of some of the forceps placed higher up, must protrude into the peritoneal cavity of the pelvis, which therefore cannot, as in the other operations, be closed above them, so as to make the stumps extra-peritoneal; consequently, from the breaking down of the tissues in the bite of these instruments, the pelvic and intestinal peritoneum is liable to be infected by putrilage. Again, the large, open channel between the abdomen and the vagina invites contamination of the contents of the former. Further, the obstruction of the vagina by the presence of such bulky instruments makes the removal of the more remote tubes and ovaries difficult, if not in some cases impossible. Finally, as Mundé observes: "They are said to produce sloughing and adhesions of intestines and omentum to the edges of the wound, and hence we believe many operators who formerly employed them have returned to the use of the progressive silk sutures." (*Diseases of Women*, p. 586.)

The objections to the progressive silk ligatures are, in my opinion, less grave, and they are as follows: When applied to the short and dense stumps of the broad ligaments they are liable to slip off. Then, again, it is true that while by their use most of their knots and the included portions of the broad ligaments can be made extra-peritoneal by closing the roof of the vagina above them, some of the knots of the upper ligatures will usually lie in the peritoneal cavity. Consequently, as one of each of the free extremities of the silk ligatures must not be cut off, but be left long, in order to facilitate their ultimate removal, there will be a liability of capillary drainage along these ligatures from the dirty vagina into the peritoneal cavity. This invites blood-poisoning, or, what is not uncommon, local abscesses, because the knot, which may hang on for three or four weeks, becomes converted into a septic foreign body.

Now, catgut ligatures are not open to these objections. If applied fresh from the alcoholic solution in which it is kept, and unmoistened by water, catgut swells up immediately, and binds more firmly than before the tissues around which it is tied. It is therefore, in my opinion, less liable to slip off than is silk. I have, indeed, never known a catgut ligature to slip, even when applied to the short and thick broad ligaments of a fibroid tumor, and to its very large bloodvessels, which have to be tied during the operation of supra-vaginal hysterectomy. Then, again, in vaginal hysterectomy the catgut ligature has this very great advantage over the silk ligature, that every ligature, high or low, can be cut off close to its knot. Hence, those knots left in the abdominal cavity are not only absorbable, and therefore less likely to become foreign bodies, but by the sewing up of the wound in the vaginal roof, also by catgut, they are cut off from the vagina and therefore from vaginal contamination. Lastly, all the extra-peritoneal ligatures will take care of themselves by absorption, and do not need, weeks after the operation, repeated vaginal examinations and repeated tugs before they can be dislodged.

The technique that I now prefer to follow is a blending of what seems to me to be the best points in Martin's and Olshausen's operations. The cervix is first thoroughly curetted and afterward charred by Paquelin's thermo-cautery. The funnel-shaped excavation is next stuffed with iodoform gauze, and its lips are sewed closely together by a continuous suture. These precautions are taken to prevent contamination of the peritoneum from any uterine leakage. The vagina now gets a thorough cleansing with soap and water, and is swabbed out with a 1 : 1000 mercuric chloride solution. The woman being placed in the lithotomy position, and the vagina opened by a short duck-bill speculum and two retractors, the cervix uteri is seized with a double tenaculum forceps, dragged downward and forward, and Douglas's pouch opened. Aided by the forefinger of the left hand in the opening, quilted sutures of catgut, with intervening spaces between them, are passed, uniting the edge of the peritoneum to that of the posterior vaginal wall. In proportion as the incision is prolonged on either side up to the insertion of the broad ligaments, additional sutures are put in. The object of these is to stop all hemorrhage and to prevent the stripping off of the peritoneum during the subsequent manipulations. To protect the peritoneal cavity and to keep the intestines from protruding, a sponge or a roll of iodoform gauze, to which a strong thread is attached, is pushed up into the pelvic opening. To distinguish this thread from the numerous other ligatures, a small piece of gauze is tied to its free extremity. The cervix being now dragged backward and downward, a transverse incision is made across its anterior surface above the os, and the bladder is stripped off with finger and knife-handle until the peritoneum is reached and opened. Here again quilted sutures are introduced to unite the peritoneum to the anterior vaginal wall.

By means of two aneurism-needles curved to the right and to the left, successive portions of the broad ligament on each side are tied and cut off from the womb; but the free extremities of the ligatures are, for the time being, left uncut. As the womb is thus gradually freed, it descends lower and lower,

until, all its attachments being severed, it is extirpated. Sometimes this can be greatly facilitated by either retroverting or by anteverting the womb, and delivering its fundus either through the posterior or the anterior vaginal incision. This manœuver is brought about by the fingers in the anterior opening pushing the fundus backward, or *vice versa*. The fundus is then seized and drawn out by forceps, or it is hooked out by the old obstetric crotchet, which has served me in good stead. Two fingers in the rectum will also give very material help. By this forward or backward displacement, as the case may be, the broad ligaments get a half-twist upon themselves, which not only narrows their width, thus lessening the number of ligatures needed, but which also places their upper and most distant portions within easy operative reach. Whenever possible, the ovaries and tubes should also be ligated and removed, because those organs are the next ones most liable to be attacked in progressive cancer of the womb and may already contain cancer-germs, and because the woman should not be subjected to the annoyance of the now needless function of menstruation.

When the womb has been extirpated, the sponge tampon is removed, the free extremities of all the ligatures on the left broad ligament are seized with the left hand, and the stump on that side is drawn down below the level of the opening in the vaginal roof. To keep it in this position, it is sewed by one or two through gut-sutures to the corresponding extremity of the incision. The same thing is done to the right stump, and all the ligatures are cut off close to their knots. I ought to have said that before this the ligatures—say those on the tube and ovary—lying too high to be made extra-peritoneal, are first cut off close to their knots. A strip of iodoform gauze for drainage purposes is now pushed up into the pelvic cavity through a small opening left in the vaginal roof, and the vagina is loosely packed with iodoform gauze. On the third or fourth day the bowels are moved, and after that both strips of the iodoform gauze—the drainage strip and the vaginal tampon—are removed. No kind of vaginal douche should be used for at least a week, and then only with great gentleness, for fear of tearing open the newly united parts.

When the vulva and vagina are ample, and the womb is not much enlarged, this operation is an easy one. But when opposite conditions exist, such as will be found in aged women, and especially in old maids, the operation is a very difficult one. It may, indeed, have to be abandoned, or be completed only by a resort to abdominal section.

Within the last six weeks I have three times performed the operation, in each case using catgut sutures. In two of the cases the operation was quite easy. In the third it proved tedious from senile narrowing of the soft parts, and from enlargement of the womb through cancer of its endometrium. In each the convalescence was so uninterrupted and so prompt as to be a surprise to me. The absence of all constitutional disturbance, the freedom from pain, and the ability of the patient to turn from side to side at will, were in striking contrast to the ordinary features of an abdominal section.

Some years ago, before the days of vaginal antisepsis, I removed by vaginal hysterectomy, using silk ligatures, two wombs affected with cancer. One woman died within four days, from the operation itself. The other perished within the year from a rapid return of the disease. Greatly dissatisfied with the immediate and remote results of this operation, I abandoned it. But very recently, indeed, after watching German operators and German statistics, I have become a zealous convert, and I now do not hesitate to assert that in vaginal hysterectomy we have a most potent weapon against a most deadly disease.

THE ETIOLOGY OF CHANCROID.[1]

BY R. W. TAYLOR, M.D.,
CLINICAL PROFESSOR OF VENEREAL DISEASES AT THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

IT is to-day clearly proved and very generally believed that the chancroidal ulcer does not depend upon a specific virus of its own, as was formerly claimed, and that, while a chancroid may be, and very commonly is, derived from a previous chancroid, a chancroidal bubo, or a chancroidal lymphangitis, it may also originate in pus derived from irritated lesions of syphilis and from irritated simple lesions in syphilitic subjects, and from various forms of simple pus, particularly when originating in active and intensely irritated lesions, and in some persons may develop *de novo*.

After the clear distinction between the chancre and the chancroid had been drawn by Bassereau in 1852, and Clerc in 1854, great efforts were made to establish the claim that two distinct viruses existed, namely, the syphilitic and the chancroidal. There was no difficulty in establishing beyond controversy the fact of the existence of the syphilitic virus, but it was otherwise concerning the *contagium vivum* of the chancroid. But ingenious reasoning, misrepresentations, and misapplications of facts surmounted the difficulties of the occasion, and by many it was considered as proved that such a morbid entity as the chancroidal virus actually existed. Thus was promulgated the doctrine of dualism, the simplicity of which was so striking that it gained quite general

[1] Read before the Section of Genito-urinary Surgery of the New York Academy of Medicine, November 12, 1891.

acceptance. But there were those that could not see anything mysterious and specific in the chancroid, and who, by means of experimental inoculations and clinical studies, threw doubt upon the existence of a specific virus for the chancroid. In this connection I may, I hope, without immodesty claim that the labors of Dr. Bumstead and myself had much to do with the inauguration of the era of light that prevails to-day. We felt that a dictum like the following, though emanating from so high an authority as Fournier, and adopted in this country by Van Buren and Keyes, should be proved to be false. It is as follows: "Chancroid is an affection perpetuated only by contagion; sexual intercourse is not essential. Wherever upon the human body a chancroid is found, there has been deposited pus from another chancroid under conditions favorable for its absorption. No amount of sexual excess, no degree of uncleanliness, no irritation, traumatic or chemical, however prolonged; no simple or poisonous ulceration from other specific sources (syphilis, cancer, glanders, etc.)—nothing, in short, can produce chancroids except chancroids (chancroidal bubo included). So that, as Fournier puts it, if all the patients in the world with chancroid would avoid contact with others until their malady got well, the disease would cease from off the face of the earth." As I have said before, by means of intelligent investigation, experimental and clinical, it was proved beyond a doubt that ulcers having all the features and peculiarities of the chancroid could be produced by many different varieties of pus, the chief essential being the activity of the ulcerating process from which the pus was taken.[1] Thus then the chancroid was deprived of its dignity as an essentially virulent ulcer and relegated to the position of an indifferent affair of hybrid and heterogeneous origin. It was to be hoped that a flood of light would be thrown upon the question of the nature of the chancroid by modern bacteriological science and research, but these fond hopes have not been fully realized.

De Luca and Ducrey have each claimed that they have isolated and cultivated a microbe that is the morbid agent in the production of chancroid; but their results are discordant, and they failed to establish a clear scientific claim. If my reading is correct (and I have been careful and painstaking), the general sentiment among those who study bacteriology is that the chancroid is the production of pus that contains the staphylococcus pyogenes albus and aureus, and perhaps the streptococcus. In fact, the chancroid bears the same relation to the mucous membranes that ecthyma and impetigo bear to the skin. So that we may state the case in this way: Chancroid is produced by pus rich in pyogenic microbes. In this thesis clinical observation and microscopy are in accord, the former proving that intensity of inflammation is necessary, and the latter that the pus is extremely rich in pyogenic microbes.

Though the profession at large is quite fully acquainted with the essential facts as to the nature of the chancroid, there are many points involved in its clinical history that are still not clear.

In very many cases chancroids are derived during sexual intercourse, one party being affected with this active form of ulceration. This form of transmission of the disease is well and generally known. It is transmission by direct descent. But it must be clearly understood that chancroids may be found on the penis of a man, and that examination of the woman with whom he cohabited may show her to be free from these lesions. In other words, it is not safe to say to a man suffering from chancroids that the woman with whom he cohabited undoubtedly had chancroids. This will be well shown by the following case:

A healthy young man, free from syphilis and gonorrhea, came to me with a rosary-like series of seven chancroids in the balano-preputial sulcus. He was surprised at the information that he had chancroids, and asserted that he was positive that the woman with whom he had cohabited had no such trouble, to which I readily assented, and I explained to him how chancroids might originate. Examination of the young woman on the following day showed that she was free from syphilis, and that her genitals were not the seat of disease, but that in the os uteri there was a deep fissure covered with a highly ulcerated surface, and surrounded by much hyperemia. From this lesion a profuse brownish, gelatinous pus escaped. The woman gave the following story: Seven years before, she had had a child, and had since thought that she was not quite right in the womb, having had exacerbations and remissions of leucorrhea. Four weeks before, she was obliged to go to bed in consequence of what was called peritonitis. Three weeks later, after getting out of the sick-bed, her lover (who had been such, and her only one for years) and she resumed their amorous embraces in a very vigorous manner, supplemented with unlimited wine, the result of which was the chancroids in himself and much pelvic pain in his consort.

In this case a discharge that had previously come from a subacute form of inflammation was, in consequence of the peritonitis and excess, transformed into a more active form of pus. Every source of error in this case was carefully eliminated.

This and many similar cases have clearly convinced me that many cases of chancroid are developed through non-syphilitic women in whom, owing to various causes, an exacerbation has taken place in

[1] For details see Bumstead and Taylor on Venereal Diseases, Introductory Chapter. Philadelphia, 1883.

some lesion of the genitals that previously was innocuous, and which then gave forth an active form of pus.[1] It follows, therefore, that we should be guarded in the cases of suspected wives and mistresses as to what we say to husbands or lovers that are unlucky enough to become affected with ulcers of the genitals in intercourse with the former. Otherwise much harm may be done, and innocent women may be cruelly wronged.

It is far from uncommon to observe chancroids in a man contracted in intercourse with a syphilitic woman who has no specific lesion of the genitals, but who suffers from a purulent vaginal secretion. In these cases the simple inflammation of the syphilitic woman gives issue to pus rich in pyogenic microbes. This again is an illustration of the statement that men may gain chancroids from women whose genitals are free from these lesions. I have many times, by means of confrontations, conclusively convinced myself of this mode of origin of chancroids, which was first brought into prominence by Morgan, of Dublin, in 1871.

Then, again, I have seen many instances in which men have cohabited with impunity with women the victims of an old and extinct syphilis, but who suffered from chronic chancroids. In these cases the ulcers had become old and inactive, and they had ceased to secrete a dangerous pus.

Now, then, I come to a portion of this subject concerning which there is a widespread want of knowledge in the minds of medical men.

Chancroid being classed as a venereal disease, the physician instinctively thinks that a given ulcer that is presented to him must of necessity have originated in sexual contact. In many cases this supposition is not correct, for chancroids may originate in some subjects *de novo*. In other words, it is not very uncommon to see chancroids in men who have had no sexual exposure whatever, such lesions being perhaps due to some inherent peculiarities of their tissues, to some diathetic condition or to debility, or to some contamination with particles of dirt that have lodged upon their genital organ. This mode of origin of the chancroid is well shown in the following two cases in which herpetic lesions became transformed into actively destructive chancroids. Such cases are far from rare, and if the practitioner will carefully interrogate the patients that come to him suffering from chancroids he will in many instances find that there has been no exposure within the time required for the development of these lesions, and he will convince himself beyond all doubt that the ulcerative lesions are due to some unknown source of contamination of herpetic vesicles, of chafes, abrasions, or fissures. I have among my notes many cases illustrating the origin of chancroid in all of these lesions and traumatisms. The chancroid in these cases is simply an evidence of wound-infection, and is really a septic ulcer.

Many years ago, when the doctrine prevailed that a man or woman having upon his or her genitals or elsewhere a chancroid must of necessity have contracted that ulcer from some other person afflicted with chancroid, a gentleman, aged twenty-nine, came to me whose case and history much puzzled me. He had had gonorrhea several times, but had never been infected with syphilis. He was fat and plethoric and claimed that he had never been sick for a day in his life (suffering from clap excepted). He showed on the inner side of the prepuce a lesion one-third of an inch in diameter, that without hesitation I pronounced to be a chancroid. The soft, yellowish, worm-eaten surface and base, the undermined edges, the peculiar secretion, and the halo of inflammatory redness produced a picture so characteristic and typical that my assertion was emphatic. But the gentleman insisted that he had not had any intercourse for a month and that he had been informed that chancroids appeared within a very few days after coitus. My reply was that he had a chancroid and that in some unexplained manner he had been contaminated with chancroidal pus. He claimed that this was impossible, and said that under similar circumstances he had had precisely similar ulcers, which, by a number of eminent surgeons and syphilographers in some of the largest cities of America and Europe had in each instance been unqualifiedly pronounced to be chancroids. For a number of years this man came to me with these ulcers. In some instances they appeared so soon after coitus that chancroidal infection seemed probable as a cause, while in others no sexual intercourse had been indulged in for several weeks prior to their appearance. Repeated careful questioning convinced me that this gentleman was the victim of persistently recurring herpes progenitalis, and for a long time it was a mystery to me why in some instances the vesicles dried and their surfaces healed promptly, and in others they became transformed into unhealthy ulcers that could not be distinguished from classical chancroids.

Whether in this case there was a tissue-peculiarity I am unable to say. The patient was seemingly in robust health; yet it seemed to be his lot to suffer (as I know now) from the ravages of pyogenic microbes that, in some unexplained manner, so persistently attacked his excoriated vesicles.

The following case is even more remarkable:

A gentleman, thirty years old, thin and rather pale, but who had never had any serious sickness, has suffered from herpes progenitalis three or four times a year for about ten years. He had severe attacks of gonorrhea when twenty-four and twenty-

[1] This clinical fact (and I can cite numerous similar cases) is in direct accord with and confirmatory of the results of experimental inoculations, made by a goodly number of observers, who produced lesions in no way distinguishable from chancroids, by the use of the pus of acne, ecthyma, impetigo, lupus, scabies, and pemphigus.

six years old. He has never had syphilis. He came under my observation in 1886, having a deep sloughing ulcer in the left groin and a similar ulcer on the thigh, just below the groin. These lesions were the sequelæ of two virulent buboes. They were thoroughly healed by curetting, followed by copious irrigation with a five per cent. carbolic solution. Then the parts having been dried, the morbid surface was dusted with iodoform, covered with gauze, and bandaged. On the anterior surface of the corresponding thigh were three little ulcers, in all respects like chancroids, and several hair-follicles were the seat of a deep hyperemia. According to the patient's statement, the lesions upon the thigh were caused by the matter that had escaped from the buboes, he in travelling being unable to dress his ulcers or keep himself clean. The lesions upon the thigh were well cleansed, dusted with iodoform, covered with gauze and bandaged. Briefly stated, it may be said that healing was brought about in all these lesions in three weeks.

As the case is thus far reported it would pass for a well-marked illustration of virulent buboes, complicated by the chancroidal ulcers of the thigh, which were produced by accidental auto-inoculation.

Let us now consider the history of the case. The patient was a very intelligent man, who, by reading and from conversations with medical men, had gained a good general idea of chancre and its consequences, and of chancroid and its sequelæ. His account of his case was as follows:

He had, as stated, for a number of years been much troubled with herpes progenitalis, which appeared before he had suffered from gonorrhea. Each attack came on with smarting, burning pain. In some instances the vesicles were seated on the skin of the penis, in others on the inner surface of the prepuce, and in others again near the frenum and the meatus urinarius. In the early attacks, the vesicles, under simple treatment, healed in about a week. As years went on, he observed that sometimes the vesicles assumed an unhealthy appearance, became much ulcerated, and were very rebellious to careful treatment. On several occasions he was forced to lay up and apply cooling lotions to enlarged and painful ganglia in the groins. Being a thoughtful man in all matters, and observant as to the results of coitus, he convinced himself that his attacks of herpes were never the result of that act. Sometimes the herpes appeared a few days after coitus, and then again it came on in regular form after many weeks' abstinence. This showed him (and his deduction was correct) that in none of his sexual contacts had he been the victim of infection. The facts concerning what took place prior to the development of the virulent buboes first spoken of are as follows: The patient had not had sexual intercourse for three months, and was suddenly attacked with a crop of herpetic vesicles, seated in the left fossa of the frenum. Being a very careful man as to the cleanly condition of his genitals, he had always been scrupulously so when he was troubled with herpes. This group of vesicles rapidly developed into a large ulcer, which a surgeon pronounced to be a chancroid, which he maintained could only have been contracted in coitus. He refused utterly to listen to the asseveration of the patient that he had not been exposed in three months. Two weeks' careful treatment, largely with iodoform, healed the ulcer, but before that consummation was reached the virulent process in the groin and thigh began, which eventuated in the buboes and the chancroids I have spoken of.

Here then was a case in which an undoubted history of herpes preputialis was given, in which infection in sexual intercourse was entirely out of the question, but in which the vesicles, from some unknown cause, became transformed into an ulcer, typically chancroidal in appearance. By means of lymphatic infection, this ulcer (for the patient had had no lesion whatever about the foot, leg, or buttocks) gave rise to two virulent buboes, the pus of which, coming in contact with the thigh, produced typical chancroidal ulcers.

During the following years, recurring attacks of herpes were experienced, in some of which the vesicles became converted into destructive ulcers. On two occasions I saw these vesicles in their unruptured condition, once on the internal layer of the prepuce and once upon the integument of the penis. In each instance I instituted a most rigid antiseptic condition, and kept the ulcers covered with iodoform without intermission, with the result of causing the vesicles to wither, and the excoriations to heal promptly, and without the least untoward complication.

In 1890, however, this gentleman came to me again under the following circumstances: Three weeks previously, not having had coitus in four months, he had again been attacked with preputial herpes near the right of the frenum. Being deeply engrossed in business, he contented himself with washing the parts and applying a mild lotion on cotton. The vesicles developed into a typically chancroidal ulcer, and the ganglia in the right groin became swollen and painful. The ulcer was treated with iodoform, and cold was applied to the groin. The chancroid healed, but the ganglia went on to suppuration. After free incision a deep ulcerated surface was left, which was as typically characteristic of a virulent bubo as any that I have ever seen. In its cure it presented the same difficulty observed in the treatment of most virulent buboes. This patient has since suffered with two attacks of herpes, but by the observance of the most rigorous antisepsis from the time of their first appearance I have been able to prevent the development of destructive ulcers.

In one particular this case is difficult of explanation. It may be that this gentleman's tissues afforded an especially good culture-ground for pyogenic microbes, for his lesions were certainly very active

and destructive, considering that he did not suffer from syphilis.

Finally, it is very important to understand the relation of an active syphilitic infection to excoriations, chafes, abrasions, and fissures about the genitals, male and female. In the first and second years of syphilis more especially, and in some instances at later periods, we find that in many cases the simple lesions just enumerated become transformed into ulcers having every feature and characteristic peculiar to chancroids. Cases presenting these features are frequently very puzzling, and it is important that their nature should be clearly understood.

Perhaps I can make the matter more clearly understood by the citation of a case that is now under treatment:

A gentleman, aged twenty-eight, has been syphilitic less than a year, and though commenced rather late, specific treatment is doing well for him. He presents four typical chancroids on the inner aspect of the prepuce. They appeared twelve days after intercourse with a woman who, under examination, was found to have a simple leucorrhea. The gentleman had for years, at irregular intervals, suffered from herpes progenitalis, and he was much impressed with the fact that in two such attacks that have occurred since his infection with syphilis the excoriations had developed into unhealthy-looking and destructive ulcers, which were difficult to cure.

In this case we find a condition very frequently observed in syphilitics. Simple inflammatory lesions of the genitals become converted into typical chancroids, or, as we may say, wound-infections, or septic ulcers, undoubtedly as the result of contamination with pyogenic microbes, the source of which is a mystery. Lesions thus produced often display great virulence, in consequence of the activity of the local infective process (staphylococcus and streptococcus infection), which seems to reach its acme in syphilitic tissues, particularly when the infection is not very old. Pus taken from these chancroids in syphilitic subjects will as a rule be seen to possess great potentiality in the extent and persistence of the ulcers and in the power that it possesses of producing by inoculation similar lesions for many generations.

In some of these cases of chancroid that develop *de novo* in syphilitic subjects, contamination of the inguinal ganglia takes place by direct lymphatic absorption. As a result we have two forms of bubo—the inflammatory, which may be aborted, and the virulent, which leads to abscess. It is very probable that in the tissues of syphilitic subjects the pyogenic microbes find a most favorable nidus. The inflammatory process to which they give rise is often very active, and the resulting pus, rich in microbes and their poisons or tissue-products, is very virulent and destructive. Observation during a long period of years has convinced me that chancroids derived from syphilitic pus (the diathesis being quite active) are commonly more destructive than their congeners that are caused by the various forms of simple pus.

It is well to emphasize the fact that in old syphilitics, male and female, in whom the diathesis has seemingly run itself out, lesions of continuity about the genitals are liable to assume the features and characteristics of chancroids. A recollection of this fact will often render an obscure case clear.

It now only remains to speak briefly of the influence of syphilis in producing chancroids in women. The tissues of the genitals of syphilitic women, like those of men similarly afflicted, are liable to the development of chancroidal ulcers *de novo* upon all forms of lesion of continuity, such as herpetic vesicles, abrasions, chafes, etc. In proportion as the disease is active and the general nutrition is lowered, these ulcers will be found to be more active and destructive—in short, more typically chancroidal. I will briefly report two recent private cases as illustrations of this statement:

A young woman of flabby build, syphilitic a year, in consequence of vulvar pruritus following menstruation scratched the surface of the right protruding nympha until it was raw. She had absolutely refrained from coitus for a month, and had not been near any one suffering from chancroids. Ten days after this paroxysm of scratching I saw her with a large typical chancroid upon the wounded nympha, and a bubo that, when opened a week later, presented every characteristic of virulence.

The next case is very similar. A young woman, fifteen months syphilitic, treated irregularly, noticed a group of herpetic vesicles to the right of the root of the clitoris. She had had similar lesions in years gone by. She had not indulged in sexual intercourse for several months. Though she applied a mild carbolic solution of her own preparation upon cotton, this group of vesicles promptly became transformed into a typical chancroid as large as a ten-cent piece. Very shortly pain in the right groin pointed to ganglionic contamination, and later on I opened as typical a virulent bubo as I have ever seen.

In the light of what has already been said as to the development of chancroids in syphilitic subjects, I need make no further comment on these cases, for they are simply other illustrations of wound-infection. They speak for themselves, and I can vouch for the correctness of the facts. Any physician who sees many cases of venereal disease will certainly call to mind similar ones, some of which may have been obscure to him.

In old prostitutes, the subjects of ancient and perhaps extinct syphilis, we find chronic chancroids that linger in an indolent and aphlegmasic condi-

tion for years and years, frequently giving their bearers very little concern, but presenting great rebelliousness to treatment. They are relics of active ulceration, and it is probable that the microbes which have caused them have become weak and attenuated, and hence are powerless for active invasion.

In this clinical summary I have endeavored to present a general outline of the mode and peculiarities of development of chancroids appearing after sexual contact, and, as we say, *de novo*, without sexual contact, or by accidental pus-contamination. The subject has occupied my mind for many years; and I believe that it is here presented in an accurate manner. I think that I have adduced evidence that proves beyond controversy that the assertions that a chancroid is always of necessity the result of chancroidal pus, and that if all the patients in the world suffering with chancroid would avoid contact with others until their malady got well, the disease would cease from off the face of the earth, are utterly false, and not at all in keeping with the present condition of our knowledge.

To sum up: What we call chancroid is the product of many varieties of pus derived from non-syphilitic and syphilitic subjects. It is therefore a hybrid, heterogeneous lesion, in all cases a septic ulcer, and in many instances simply an active form of wound-infection. This septic ulcer in some cases originates *de novo* from the contact of pyogenic microbes with a raw surface, herpetic or eczematous excoriation, a chafe, etc., sexual contact then having nothing to do with its development. As a general rule, this local infective process is more active in syphilitic than in non-syphilitic subjects. It follows, therefore, that so long as pyogenic microbes and tissue-predisposition exist, chancroids will be found upon the mucous membranes and integument of the human race.

40 WEST TWENTY-FIRST STREET.

GONORRHEAL RHEUMATISM: ITS EFFECTS AND TREATMENT.

BY BERNARD E. BRODHURST, F.R.C.S.,
MANCHESTER, ENGLAND.

IT is certain that gonorrheal, or urethral, rheumatism is in the first instance invariably preceded by a specific discharge. Subsequent attacks may or may not be preceded by a discharge; but the first attack is always preceded by a specific urethral discharge. A second attack of articular rheumatism may be caused by the use of the bougie, or by an act of coition, or by any other form of irritation of the urethral canal.

Exposure to wet and cold weather, the gonorrheal discharge being present or about to appear, tends to induce this form of articular inflammation. Considerable effusion into the affected joints takes place, accompanied with great pain; but, although tension may be very great, suppuration never occurs. Many joints usually become inflamed simultaneously; and all may recover perfectly and without leaving behind any ill results. Every fresh attack of inflammation takes more effect than the preceding one, and seems to be more virulent in its character; and it is probable that although on two occasions the joints perhaps resume their normal appearance and their functions, a third attack may leave the patient lamed. It is common that all joints recover well except one, but that one remains stiff and immovable.

When pain is first felt, and swelling appears, the affected joints should be wrapped in lint covered with mercurial ointment, and they should be bandaged as firmly as can easily be borne, and the patient should be brought rapidly under the influence of mercury, preferably by inunction, with which treatment pain and swelling quickly disappear, and the joints resume their normal condition. At this stage passive motion should be instituted to ascertain that the motion of any affected joint is free, for lymph will have been deposited on the synovial membranes, through which adhesions form that prevent motion. These bands soon become firm, and resist any attempt that a patient himself can make to move the joint. These constitute false ankylosis. The mercurial treatment to which I have referred, if resorted to at the onset of the inflammatory stage, never fails. Swelling subsides as the mercury takes effect.

The large joints, namely, the knee, the hip, the elbow, and the shoulder-joints, are those that are most frequently affected. Every joint, indeed, may become inflamed, and ankylosis may result, not in one joint only, but in every articulation of the body. Such a case I have had under my own care. I saw this patient with Dr. Lever. He had had three attacks of gonorrheal rheumatism, each of which was preceded by a specific urethral discharge. He recovered the use of his limbs after each attack, but each occasion required longer time for recovery than the preceding one, and the third attack left a certain degree of stiffness that was never entirely removed. This, however, appeared to be muscular rather than articular, and it was only felt after a long rest in one position. At length he married. After marriage he was seized with violent inflammation. Every articulation was inflamed, and became ankylosed. At this time I saw him, and he could neither move his head nor any limb, nor could he masticate. He lay like a log, without power of motion.

When adhesions remain and become firm, after inflammation has ceased and passive motion has

not been employed, force is needed to restore mobility. If this force is employed in extending the limb, dislocation may be produced, or at least some displacement of the articular surfaces may occur. Force should therefore always be used in the direction of flexion. When force is thus employed no injury can accrue to any structure, and, if this operation has been long delayed, so that contraction of the flexor muscles cannot otherwise be overcome, their tendons should be divided. But, before force is applied to rupture adhesions, the punctured wounds should be allowed to heal, for otherwise they may readily be extended into lacerated wounds from three to four inches in length. In this manner mobility is very quickly regained. The operation is entirely successful, and it ranks among the most satisfactory in the whole range of surgery. I operated in this way, with Mr. Henry Lee, on an elbow. Disease had been contracted in China, and several joints became inflamed. All, however, recovered except the elbow. This joint became perfectly stiff and immovable. Under chloroform the adhesions yielded instantly and completely, and mobility was restored. In the course of one month he returned to China, having recovered the entire use of the joint. Three years later I met him accidentally, and inquiring as to his elbow, he answered: "Really, I have forgotten which was the stiff elbow; both are alike"—at the same time rapidly flexing and extending the forearms.

With Dr. William Wood I saw another case in which disease had been contracted in Ceylon. In this instance the patient slept in the open air, and awakened cold and in great pain. With difficulty he was carried to his own room, the hip, knee, ankle, and shoulder joints being much swollen and dreadfully tender. The hip became so much swollen that it was supposed that suppuration would occur. This joint became stiff and immovable, but all the others recovered perfectly. Sir Benjamin Brodie advised that he should arrange to leave the army, because he would not be able to follow his profession, as he could neither ride nor walk, and "he would take his stiff joint with him to the grave." From Sir Benjamin's house he came to me, and I told him that mobility could be restored. The adhesions yielded with very slight force, and gave way gradually, so that the thigh, which had been fully extended, was flexed upon the pelvis. He suffered no pain, and slept well without an opiate. Passive motion was used, and in some few days he walked about his room, and within a fortnight he walked upward of two miles without injury. In two months I presented him at the Royal Medical and Chirurgical Society, where he was examined by many, and especially by Mr. Coulson, who affirmed that, unless he had heard it from so many credible witnesses, he could not have believed that the hip-joint had ever been diseased, because the head of the femur moved perfectly in every direction. Speaking immediately after the paper was read, in which this case was detailed, and before he had examined the patient or knew that he was present, or that he was an officer in the Queen's service, Mr. Coulson affirmed that the case was impossible, to the great astonishment and amazement of my patient, who was sitting at my side. Immediately afterward the patient rejoined his regiment. Writing to me some few months later, he said: "I walk occasionally twelve or thirteen miles a day;" and again, later, he wrote: "I can sit in the saddle all day without pain."

I have also operated, with Sir Prescott Hewett, on the hip, disease having been contracted in Russia, and on another case from India; with Sir William Ferguson I also operated on both hips and both knees in a case from Bermuda—as well as in many other cases, in which mobility has been perfectly restored.

Ten years ago I had operated on upward of 1000 cases of fibrous ankylosis, and in no instance, either before that time or since, have I met with any accident, whether displacement, fracture, inflammation, or injury of any kind whatsoever.

TWO NEW CASES OF FILARIA SANGUINIS HOMINIS.

By R. M. SLAUGHTER, M.D.,
of Theological Seminary, Virginia.

In August of the present year I made the, to me, interesting discovery that indigenous cases of filaria sanguinis hominis are to be found in Virginia. During that month, in two instances, while making microscopic examinations, I found in urine unmistakable specimens of the embryo filaria sanguinis hominis, and I give below the clinical histories of the cases from which the specimens were obtained.

It is well known that indigenous cases of filaria sanguinis hominis are to be met with in our Southern States. This has been established by the observations of Guitéras, De Saussure, and others. So far as I have been able to ascertain in a careful investigation in the Library of the Surgeon-General of the Army, in Washington, D. C., twenty-three cases have been reported up to July, 1891. Reports of some other cases are to be found, it is true, but they are not indigenous, for the patients were natives of warmer latitudes.

Of the twenty-three cases mentioned, Dr. de Saussure, of Charleston, S. C., has reported twenty-two. (See The Medical News, June 28, 1890.) The remaining case is that reported by Dr. W. M. Mastin, of Mobile, Ala., and reported in

a paper read at the meeting of the American Association of Genito-urinary Surgeons at Washington in September, 1888 (*Annals of Surgery*, vol. viii, No. 5, November, 1888). My discovery of these two cases in Northern Virginia extends, then, the area in which indigenous cases have been encountered to nearly as far north as the thirty-ninth parallel of latitude, which is about that of Washington, D. C.

The following is the history of these cases:

CASE I.—Miss —, a maiden lady, about sixty-five years of age, was born in Richmond, Va., and has resided in various portions of the State, but for the last twenty-five years at Theological Seminary, which is six miles southwest of Washington, D. C. She has enjoyed remarkably good health all her life. About the first of August last, she returned home from a visit to Richmond, looking and feeling very badly. She appeared anemic and complained of feeling weak and always tired; had diarrhea, and irregular, slight chills and fever at night. The treatment instituted entirely failed to relieve her, and, as I feared renal trouble, I asked for a specimen of her urine for examination. I was then told by the family that it had been noticed for some years that at times her urine "did not look right." The sample was bloody and chylous. The case was one of chylo-hematuria, which a microscopic examination showed to be of filarial origin, many embryo filaria being found in the sediment. There was no evidence of renal disease. The annexed illustration shows the appearance of the filaria.

For the next few weeks the patient displayed a tendency to the formation of furuncles about the face; a small alveolar abscess formed above the upper incisors, which I opened; on examining the pus I found several embryo filaria therein. It may be worthy of mention that some twenty or more years ago she suddenly became quite deaf and remained so for several months, when an abscess formed in the mouth. When this was opened the deafness disappeared. Careful inquiry into her past history has elicited no other facts having any bearing on the case. Under treatment, consisting of tonics and astringents, the diarrhea has ceased and her general condition has greatly improved.

CASE II.—Mrs. —, white, about forty-five years of age, was born in Fredericksburg, Va., and for the last twenty years has lived in Alexandria, Va. She is a patient of Dr. W. R. Purvis, of Alexandria, and has recently been under treatment for hysterical paralysis. She conceived an idea that she had Bright's disease, and a specimen of her urine was handed me by Dr. Purvis for microscopic examination. This specimen I found to be chylous and to contain numerous embryo filaria. I have since examined a second specimen, which was also chylous and contained filaria. In this case the chyluria is the only manifestation of the presence of filaria that has been observed, unless the hysterical condition be so regarded, and for this there would seem to be no sufficient reason.

In neither of these cases have I yet been able to examine the blood.

The most common manifestation of the presence of filaria in the human subject, in indigenous cases especially, is chyluria. In many cases it is the only symptom; in some it is associated with others, such, for example, as hematuria, lymphangitis, enlarged glands, abscesses, dysentery, diarrhea, or lumbar pains, etc. In some cases chyluria has not been observed, the leading manifestation being hematuria, chylocele, or scrotal elephantiasis, or lymph-scrotum.

In those countries in which the disease is quite common, a formidable array of pathological conditions has been found associated with filaria. According to Bancroft, Fayrer, Sonsino, Manson, and others, the following are to be found so associated: Chyluria, hematuria, anemia, tuberculosis, chylocele, varicocele, elastic tumors in axilla and groin, lymph-vesicles bursting on scrotum and abdomen, skin diseases (craw-craw), acute orchitis, lymphangitis with fever, erysipelatous lymphangitis leading to hypertrophy of the skin, elephantiasis of the scrotum, and abscess of the scrotum, of the glands of the neck, of the lymphatics of the arm and thigh, intra-pelvic abscesses, peculiar steatoma of the face, venous varix, cerebral abscess and other lesions of the brain, cachexia, deterioration of the general health, deafness, eye diseases, etc.

The subject, I would say in conclusion, seems to me to offer an interesting and possibly extensive field for future investigation.

Stoerk, of Vienna, has succeeded to the Laryngological clinic of Schrötter, who has been given a professorship of Clinical Medicine and a medical clinic.

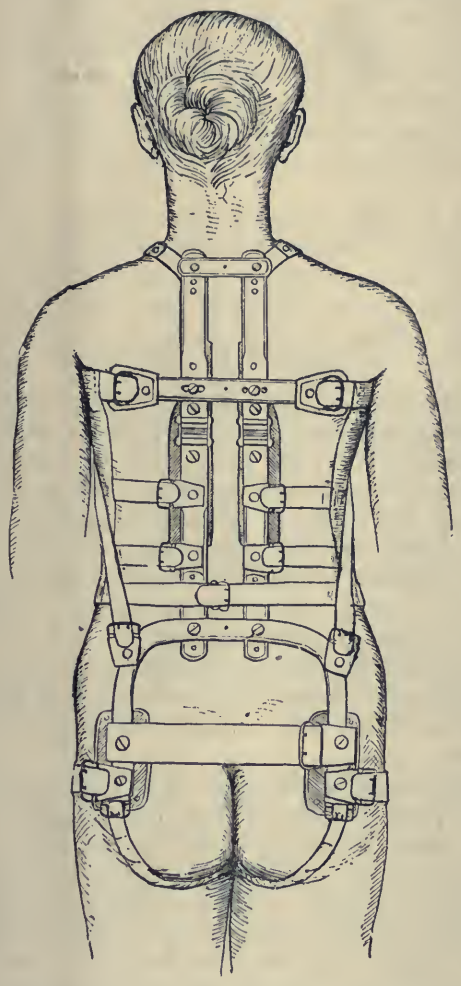
Prof. Carl Fraenkel, of Königsberg, has been elected to the chair of Hygiene at Marburg, in succession to Rubner, called to Berlin.

THE VALUE OF MECHANICAL TREATMENT IN OLD AND NEGLECTED CASES OF POTT'S DISEASE.[1]

BY HENRY LING TAYLOR, M.D.,
OF NEW YORK.

ONE of the most active and eminent operative surgeons of New York said to the writer, not long ago, that he got but little bone-surgery to do, because orthopedic work was so successful. Not the least important service that the pioneers in orthopedy have rendered to the profession and to the public is the diffusion of the knowledge of the

FIG. 1.



relative curability of most crippling affections; and, as a matter of fact, the adult cripple in our large cities is now much less conspicuous than formerly. There is a class of sufferers, however, still unfortunately numerous, and for whom professional advice is often sought, namely, the class of kyphotics, in whom the inflammatory process has dragged out its tedious course through years of suffering and increasing deformity, and who, on account of inadequate treatment or too little persistence, have found no relief. The results of neglected and unsuccessfully-treated Pott's disease are so serious, and in many respects so irremediable, that it seems desirable to ascertain under what circumstances and how far their unfortunate condition can be mitigated.

The orthopedist sees cases of spinal caries in all stages, from a time preceding the appearance of spinal deformity to the aggravated hunchback, with or without severe constitutional symptoms, and in whatever stage presented, modern mechanical

FIG. 2.

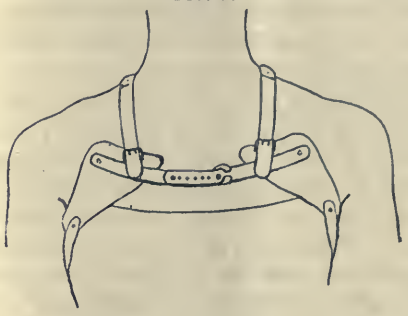


FIG. 3.

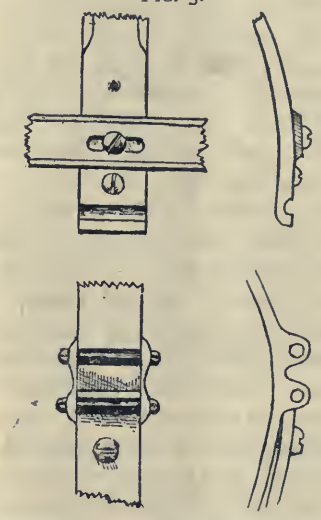


treatment seeks by appropriate methods to procure rest and protection from violence for the inflamed spine, and to arrest, and in exceptional cases to rectify, accrued deformity.[1] The means employed by the writer to secure these results depend upon the principle of antero-posterior leverage, so applied to the spine by means of a specially-adapted apparatus[2]

[1] Read before the American Orthopedic Association, Washington, September 23, 1891.

[1] See "The Cure of Pott's Disease with Recession of the Deformity," Medical Record, January 8, 1887.

[2] "Description of Improved Spinal Apparatus," Transactions American Orthopedic Association, vol. i, page 15, and Medical Record, November 19, 1887. See also "The Mechanical Treatment of Angular Curvature, or Pott's Disease of the Spine," by C. Fayette Taylor, M.D., Transactions N. Y. State Medical Society, 1863, etc.

as to relieve the carious bodies of the vertebræ of harmful pressure. This may be supplemented by short periods of recumbency, daily rests, and other hygienic remedies. It goes without saying that, the earlier in the disease the case is treated, the better the average result; but what measure of relief does such treatment offer to long-standing and greatly deformed cases?

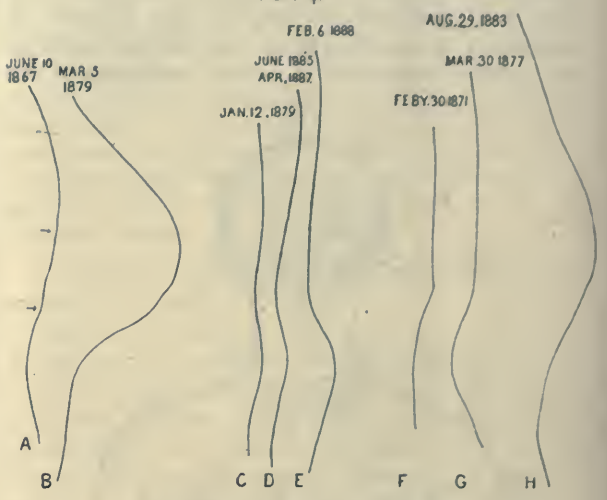
We must distinguish between treatment of the deformity and treatment of the disease.

If the case in question has no longer any constitutional symptoms, no symmetrical, lateral, or ventral pains, no reflex rigidity of the spinal muscles, and no sharp knuckle, but an evenly rounded boss; and if he can move about freely, without distress or exhaustion, the disease has probably spent itself, and the vertebræ and peri-vertebral regions have been more or less successfully pieced out with new tissue, which may, however, be inelastic or imperfectly nourished, and liable at some future time to a recurrence of inflammatory softening, after the infliction of unusual violence, or through impairment of general nutrition. These cases of spent Pott's disease, with large deformity, may be energetic and active, and in business or professional life hold their own well, but they work on a small margin, and at a disadvantage, as the result of crowded viscera, impeded respiration, and a body in which no organ has free play. I remember a middle-aged and cruelly deformed hunchback, who worked as a heavy porter at one of our railway stations, but his face showed the strain he was under, and after a few years he disappeared from his post. Efficient mechanical treatment in the earlier stages provides the sufferer with a substitute backbone, and, by relieving the organism in a great measure from the strain it is under, favors a more perfect bodily development and growth, while deformity is being checked and the healing process inaugurated. Many cases, however, run their course, or a large part of it, without pain, or with so little pain, and so noteworthy an absence of striking symptoms, that the patient and his guardians are often lulled into false security when help is most needed; and at certain stages the surgeon himself may be at a loss to decide positively as to the presence or absence of disease.

I show the tracing from the back of a boy who came in 1867, at nine years of age, with beginning spondylitis (Fig. 4, A), but who declined treatment, and reported twelve years later with a severe hunchback (B), and a freely discharging sinus. He was led by the mildness of his symptoms to indulge in athletic exercises, such as riding and fencing, to within four years of his second visit.

A boy of fourteen, from Chile, S. A., with a large kyphosis of the mid-dorsal region, who consulted me a year ago, came wearing a plaster-jacket. His disease began at four; at eight he was apparently well; but, after violent exercise, symptoms recurred, followed by a paraplegia lasting six months. This patient was kept recumbent for five years, and had recovered perfectly from his paralysis. In spite of his deformity and his desire for support, as evidenced by the jacket, he had lately been in the habit of playing cricket.

FIG. 4.



A delicate boy, with disease of the lumbar region, who had done well, and whose deformity had been controlled (C D) for eight years by mechanical treatment, was free from symptoms, but after a six months' trip to Europe, taken without my approval, his deformity increased considerably (E), and there were symptoms of vertebral softening. It has taken several years to regain the ground lost; indeed, there is more irreparable damage.

The following case may illustrate the liability of deformity to increase from lack of spinal rigidity after all disease may reasonably be supposed to be absent:

The patient, a girl, came in 1871, at the age of three years, with a sharp knuckle in the upper lumbar region, as shown in the pattern (F). After nearly six years of mechanical support, during which an abscess appeared and healed, her deformity was rounded and less prominent (G), and she was in good health, and free from symptoms. She was considered free from disease, but continuance of support was advised, lest there should be further increase of deformity from slow yielding of recently healed tissues. This advice was declined, and the apparatus discarded. Six years later, when thirteen, she reported with a large increase of rounded projection (H), but in good health, and with no recurrence of symptoms.

Cases that have been allowed to run along without adequate treatment often fail to heal completely,

and are especially liable to exacerbations and relapses.

A gentleman of fifty, who was attacked with disease in the dorsal region at nine, came to me last year still wearing a corset. At thirty-nine he was completely paraplegic for four months, but recovered, and presented at his visit to me no positive evidence of disease. He had never had an abscess, but his deformity was of the extremest grade, and he appeared to be about four feet three inches tall.

A gentleman of forty was seen in 1883. His disease was in the dorsal region, and began at the age of five. He had been kept recumbent for two years, and had afterward had imperfect mechanical treatment. At about twenty he had had three attacks of paraplegia, and since then he had had reflex twitching of the legs, and from time to time attacks of pain. Deformity was very severe, with the apex of the projection in the lower dorsal region. After thirty-five years, disease was undoubtedly still present.

A gentleman, about thirty, who came to me a few years ago with extreme deformity, had had his disease from childhood, but was free from symptoms for many years, until he was injured in a cyclone three years previously. He was an exceptionally energetic and active man, but had been obliged, by the severity of his symptoms, to give up everything. Careful mechanical treatment caused the disappearance of all symptoms, and his deformity did not increase during five or six years. After leaving off support, however, he injured himself again, and in a short time symptoms of softening recurred, and the deformity increased considerably.

Many of these relapsed cases; and those that have been affected for years by a spondylitis of low grade with gradually increasing deformity, respond kindly to treatment, and may be restored to health and activity.

Some of the cases cited would seem to suggest that a complete bony ankylosis after Pott's disease is much later, rarer, and more circumscribed than has usually been assumed to be the case.[1]

If one will take the pains to make a series of lead tracings of the kyphosis in a number of so called "ankylosed" cases, from time to time, repeating the observations on the same cases under different conditions, this statement will not seem too strong. This is also well shown in patterns taken before and after suspension in these badly deformed cases. Changes in the contour are observed that can hardly be wholly explained by compensation in the unaffected portions of the spine. Such cases can often add an inch or two to their height by a voluntary attempt to straighten. In many of the early cases, cured with little or no deformity, motion in the diseased areas can also be demonstrated. This explains the necessity of prolonged treatment after subsidence of symptoms, and the slow yielding of the newly healed spine, which often occurs even without recurrence of rational symptoms, when support is inefficient or too soon discontinued; also, the liability to relapse from accident or other causes after long periods of immunity. It explains, too, the benefit to be obtained in certain cases from mechanically relieving the patient of the effort of self-support, even when there is little or no sign of disease. The patient's column is out of balance, and has to be supported with great effort by the patient's debilitated muscles in their disturbed relations.

In cases of Pott's disease of long standing and great deformity, whether in children or adults, the indications for carefully adapted and long-continued mechanical support to the spine are as clear and often as urgent as in recent cases, and such treatment is usually followed by gratifying and sometimes by brilliant results. Even when it is too late to improve the deformity the patient may often be restored to health and usefulness, and when no symptoms of disease are present a moderate improvement in the figure and carriage may occasionally be attained. No patient should be denied an opportunity for relief on account of age, severity of the symptoms, or the long duration of his disease.

Mr. Noble Smith, speaking of the lateral curvature, is reported to have said recently:[1] "The surgeon should keep the mechanical treatment in his own hands, just as much as he would that of a broken limb." In Pott's disease, at least, he should also continue to control the case until the patient is sound and the spine is self-supporting.

ORIGINAL LECTURE.

ARTHRITIS FOLLOWING TYPHOID FEVER.

Abstract of a Clinical Lecture
Delivered at the Woman's Hospital, Philadelphia.

By FREDERICK P. HENRY, A.M., M.D.,
PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE IN THE WOMAN'S MEDICAL COLLEGE OF PENNSYLVANIA.

You saw this patient two weeks ago, when I introduced her as a typhoid convalescent and made some remarks upon the proper treatment of the convalescent stage of enteric fever.

Her recovery, which until quite recently was steadily progressive, has been interrupted by an affection of the left elbow-joint. You observe that the forearm is flexed at an obtuse angle, and that when I attempt to extend

[1] Last meeting of the British Medical Association.

it or flex it still further, I almost immediately meet with a resistance that is evidently articular.

There is some swelling of the joint, most marked between the internal condyle of the humerus and the olecranon process, but no great degree of tenderness, and no redness whatever.

This condition, having made its appearance after the complete subsidence of the fever, is probably to be ranked among the sequelæ of typhoid. Had it occurred during the course of the fever, it might have been regarded either as an intercurrent affection or as a complication. It may seem immaterial to discuss the question whether a disease occurring in the course of another is a true complication or a mere intercurrent affection, but the position of medicine as a science has been achieved by noting and preserving such distinctions. An intercurrent affection is something accidental—*i. e.*, no more liable to happen to a patient affected with a given disease than to one not so affected; while a complication is a disease, or a process, secondary to and more or less dependent upon another. Intestinal hemorrhage, intestinal perforation, and rupture of the spleen are complications of typhoid fever; the latter exceedingly rare, but none the less a complication. Erysipelas, pneumonia, and diphtheria, being due to separate infections, are intercurrent affections. Every affection that follows typhoid fever is not entitled to be called a sequela. There must be an etiological connection between them. The stage of convalescence from typhoid fever is one of great physical susceptibility. The immunity from one infectious disease that has been conferred upon a patient who has successfully passed the ordeal of typhoid fever, is at the price of a temporary increased liability to other affections. These, however, are not, as just stated, necessarily sequelæ except in an etymological sense, for their only connection with typhoid fever may be chronological. It must be confessed that it is sometimes difficult to recognize the etiological connection between the sequela and the primary disease. The tendency to confound the *post hoc* with the *propter hoc* is notorious, but there are certain guiding lines that, in most cases, will lead to a solution of this interesting diagnostic problem. One of them is *continuity*. For example, the mental faculties are always more or less impaired in cases of typhoid fever, but in mild cases this may be almost unrecognized, because no demands are made upon them. If, however, after fever has ceased and muscular strength has returned, we observe a marked insufficiency in the performance of mental operations, we naturally attribute the condition to the recent fever. There has been no return of mental health. The recuperative powers of the body have, in this instance, been greater than those of the mind. In this manner we recognize melancholia, dementia, and mania, as sequelæ of typhoid fever, even though they may have been preceded by an interval of apparent mental health. To compare small things with great, the alopecia that follows typhoid fever is recognized as a sequela not only because of its constant occurrence, but because it is known to be a result of febrile processes in general. Peripheral neuritis is a genuine sequela of typhoid fever, although not so frequently a result of the typhoid as of the diphtheritic poison. Before regarding peripheral neuritis as a genuine sequela of typhoid fever, we should, however, be able to exclude the action of severe cold and traumatism.

Arthritis is an undoubted sequela of typhoid fever, though a rare one, and it is recognized as such by certain peculiarities that distinguish it from other non-typhoidal forms of inflammation of the joints.

There are certain facts connected with this case that make it somewhat exceptional. The patient is a woman, thirty years of age, who previous to the attack of typhoid fever was perfectly healthy. Now, statistics show that arthritis in the course of typhoid fever is more prevalent in males than in females—according to Keen[1] the proportion is 3 to 1; according to Bazin,[2] 4 to 1.

It has also been proved statistically that the affection is most frequent at about the age of eighteen, and in individuals of scrofulous diathesis. The hip, knee, shoulder, ankle, and elbow are the principal joints affected.

The chief questions connected with cases of this sort are: 1. Is the arthritis a manifestation of rheumatism brought to light by the typhoid fever? 2. Is it a manifestation of pyemia? 3. Is it an affection peculiar to typhoid fever and induced by its specific poison—*i. e.*, is it a genuine sequela?

The disease differs materially from rheumatism in several fundamental particulars. In the first place it is monarticular; secondly, it has a marked tendency to suppuration and to the formation of ankylosis; and, finally, it has no tendency to involve the heart.

The question whether the affection is pyemic is sometimes more difficult to decide than in the present instance. In one patient the joint-affection was not ushered in by chill, fever, or, in fact, by any constitutional symptoms. The temperature has pursued a regular course; the appetite and digestion have not been impaired, and the patient has been steadily improving. The onset and progress of the joint-disease have been most insidious. Pyemia may certainly be excluded, notwithstanding the fact that there was a focus of suppuration due to a hypodermic injection of ergotine administered on account of intestinal hemorrhage.

The arthritis must, therefore, be regarded as due to the typhoid infection, and consequently as a genuine sequela.

The prognosis of these arthritic complications is by no means unfavorable. As a rule, according to Keen, the effusion is gradually absorbed, and the joint is restored to its former usefulness. There is one possibility that particularly concerns the hip-joint, namely: spontaneous dislocation. The distention from fluid is sometimes so great as to stretch and weaken the ligaments, so that in lifting the patient in the usual manner, by placing one arm under the back and the other beneath the knee-joints, there is danger of the head of the femur slipping out of its socket.

With reference to treatment, salicylate of sodium, and, in fact, all the salicyl compounds, have been proved useless—another argument (*ex juvantibus*) against its rheumatic nature. Quinine is much more likely to be of service. The joint should be placed in such a position as to make it most useful in case of subsequent anky-

[1] Toner Lecture, 1876, On the Surgical Complications and Sequelæ of the Continued Fevers.

[2] Thèse de Paris.

losis. For example, the arm of this patient should be flexed to such an extent as to enable the hand to reach the mouth, so as to take part in the act of eating.

Blisters and tincture of iodine are both serviceable, and of the two I would give the decided preference to the first. The system should be supported by suitable food and tonics, and the nutrition of the muscles concerned in the motion of the joint should be maintained by massage and faradization. The latter injunction is most important in case the disease is of protracted course; for there is undoubtedly an intimate trophic connection between the joints and the muscles, or, to state it differently, the atrophy of the muscles connected with a diseased joint is greater than can be reasonably attributed to mere inaction.

CLINICAL MEMORANDA.

A CASE OF SUPPURATIVE PYELO-NEPHRITIS CONSEQUENT UPON RENAL CALCULUS; NEPHRECTOMY BY LAPAROTOMY; RECOVERY.

By MANNING SIMONS, M.D.,
PROFESSOR OF GENERAL SURGERY IN THE MEDICAL COLLEGE OF THE STATE OF SOUTH CAROLINA.

Mrs. B., an energetic, healthy woman, the mother of five children, called at my office in the early part of the month of June, 1891, for advice, complaining of an uncomfortable feeling of weight and tension in the lower portion of the right side of the abdomen. She had suffered no pain, nor was she conscious of any failure of health.

By palpation a lobulated tumor was discovered on the right side, extending from the lower margin of the ribs to the crest of the ilium, reaching well over to the left side beyond the median line. It seemed to be a tense cyst, elastic, but without fluctuation. It was perfectly movable, and could be traced well back toward the right lumbar region. The uterus was found to be of normal size, and perfectly free in movement, having apparently no connection with the tumor. The true pelvis was not encroached upon by the mass, and the uterine appendages seemed to be in no manner involved. I judged that the tumor was connected with the right kidney. Pus in large quantity was found in the urine, and upon this evidence a diagnosis of pyelonephrosis was made, but, as there had been no previous history that would indicate the presence of renal calculus, we were unable to arrive at the ultimate cause of the condition. Puncture and aspiration were not thought advisable.

The patient was admitted into St. Francis Xavier's Infirmary on June 30th, and prepared for operation.

A careful estimate was made of the quantity of urine passed from day to day—an average of a quart in twenty-four hours; and microscopic observations of the urine were made for casts or other information, with negative results.

It was determined to perform laparotomy in preference to the lumbar operation, and on July 2d, with strict antiseptic precautions, an incision four inches in length, commencing about an inch above the umbilicus, was made at the outer border of the rectus muscle, through the linea semilunaris. This line was selected in preference to the linea alba, as lying nearer the middle of the tumor. The abdominal cavity having been opened, the tumor presented itself in the opening, and a sound was made to sweep over it in search of adhesions. This instrument glided so smoothly and met with so little resistance, that it immediately became evident that the growth was retro-peritoneal. The peritoneum was, therefore, incised, when it was found that the abdominal incision was not sufficiently extensive to permit the tumor to be turned out; and it was, therefore, lengthened upward to six inches. Even with this increase of working-room the tumor could not be dislodged, and it became necessary to separate the adherent peritoneum, by peeling it off with the fingers. This procedure permitted me to verify the connections of the mass with the right kidney. Before the tumor could be turned out through the abdominal wound, however, it had to be enucleated from a thicker capsule or investment. This having been accomplished, the mass was readily brought out and its connections isolated. The tumor then ruptured spontaneously, and nearly a pint of pus was poured upon the table.

The connections of the tumor formed a short pedicle about two inches in diameter, made up of the renal vessels and ureter with their connecting tissues. This was transfixed with a Tait's forceps and tied in two portions with silk ligature, the last turn of the ligature including both portions of the pedicle. The lower extremity of the ureter could not be found, and therefore it had to be left untied.

The tumor being removed, a cup-shaped cavity was left represented by the envelope from which it had been enucleated, at the bottom of which was the ligatured pedicle. All ragged ends of tissue were removed with scissors, and the abdomen was flushed with boiled water. There was but little hemorrhage, but an extensive raw surface was left, from which it was probable a large amount of oozing would take place.

To meet this indication, drainage had to be provided for at the most dependent portion of the abdominal cavity practicable. A large-sized rubber drainage-tube was, therefore, passed entirely through the cavity antero-posteriorly from the upper end of the parietal incision through the bottom of the cup-shaped cavity left at the site of the tumor and brought out at the back, at the outer border of the erector spinæ muscles, two and a half to three inches from the lumbar spinous processes, and mid-way between the last rib and the crest of the ilium. The abdominal wounds were closed and dressed in the usual manner.

The operation from beginning to end consumed about forty minutes, and the patient recovered well from the anesthetic, and there was but little, if any, shock. In the evening there was some reaction, the temperature being 99.5°; the woman was somewhat restless, but had refreshing sleep; there was, however, some nausea, some probably as a result of the anesthetic. One and a half pints of urine were passed between the time of the operation and the hour of evening observation. The dressings were not disturbed, but on the morning of the second day, July 3d, as the temperature reached 100° and there was some pain at the site of the wound, the dressings were removed in order to permit of examination. There

had been a considerable discharge of a bloody nature through the posterior extremity of the drainage-tube. The cavity was, therefore, washed out through the drainage-tube with Thiersch's solution, and the wound was dressed again as before. There had been passed one pint of urine since the observation of the previous evening, and the woman had had a comfortable night.

On the third day, July 4th, the morning temperature was 99¼°. The abdominal wound was not disturbed, but the drainage-tube, from which there was very little discharge, was pulled down from the posterior end and about two inches cut off. A calomel powder was administered, followed by two and a half Seidlitz powders given in doses of half a powder every half-hour until the bowels moved. Five movements resulted.

For the first twenty-four hours the patient was allowed only a teaspoonful of hot water every hour, but on the second day, as the nausea still persisted, half of an effervescing soda powder was administered every hour or two, with the result of relieving that distressing symptom. On the third day she was permitted to take milk and lime-water in small quantity and at long intervals.

On July 5th the quantity of urine had increased to a quart in twenty-four hours, and chicken-broth was added to the nourishment. On July 7th (fifth day) the drainage-tube was removed through the posterior opening. On July 9th (seventh day) the sutures were removed and the wound appeared to have healed throughout, except at the upper extremity, where the anterior extremity of the drainage-tube lay, but suppuration had taken place at the site of several of the deep sutures, despite the care with which they had been prepared. The cavity was still washed out each day through the posterior opening with Thiersch's solution.

On July 15th (thirteenth day) the temperature, which up to this time had ranged from 99.5° in the morning to 100° at night, rose to 101°, in consequence of the development of small abscesses at the points of the deep sutures on both sides of the abdominal incision. These openings were enlarged to permit proper drainage of the pus, and the cavities of the abscesses touched with carbolic acid. The temperature remained high, with considerable oscillation between morning and evening, varying from 99.5° A.M. to 102° P.M., until July 22d (twentieth day), when the posterior opening, which had apparently solidly healed, was opened and a considerable quantity of pus was discharged. From this time the temperature remained normal.

August 1st (thirtieth day) another abscess at a suture-point was discharged at the lower extremity of the abdominal incision. After this occurrence the patient rapidly improved, and on August 10th (thirty-ninth day) she was up.

The tumor was examined by Dr. Eugene Wasdin, Professor of Histology and Pathology in the Medical College of the State of South Carolina, who reports that he found "a kidney measuring fifteen centimeters in length by twelve centimeters in breadth, lobulated and fluctuant to the touch, with much fat about the hilus. The lobules were five in number and proved to be dilated pus-sacs, the thickened capsule forming their membranes. From these at least 400 c.c. of disorganized kidney-substance and pus were taken. Occupying the pelvis and the calices and projecting into these pus-sacs was a large uric-acid calculus with an outer covering of ammonio-magnesian phosphates. About the capsule there was an extensive growth of new connective tissue firmly embracing it. So extensive was this tissue that it obstructed the exit of purulent débris from the sacs above the stone. Careful section revealed the utter absence of any trace of parenchyma. The growth of connective tissue might account in some degree for the absence of renal pain."

The stone weighed one ounce.

CASE OF AMEBA DYSENTERY; WITH AUTOPSY.

BY EUGENE WASDIN, M.D.,
OF CHARLESTON, S. C.

I WOULD add to the cases of ameba dysentery thus far reported, one that in many characteristics is very typical.

E. C., white male, about sixty years of age, a native of South Carolina, was admitted to the City Hospital on September 9th, suffering from chronic diarrhea, and died September 21, 1891. He had been absent from home in Charleston for a long time, the greater portion of which he spent in Savannah, Ga., the fortnight immediately preceding admission having been spent in Aiken, S. C. He was very weak and deaf, and it was impossible to obtain a perfect history of his illness, but his son assured the visiting physician that his father was taken sick in Savannah, and that it was due to the use of "river water."

At the time of admission the patient must have been ill about four weeks. His skin was dry and harsh, the tongue coated, the temperature 38° C., the pulse 100 and weak. Examination revealed no pulmonary trouble, the heart-sounds were clear, the liver-area slightly increased, the spleen normal, the abdominal walls flaccid.

During the twenty-four hours succeeding his admission there were eighteen evacuations of a thin, yellowish material, containing particles of food-débris, but no blood or glairy mucus. These discharges increased in frequency, and the patient died from exhaustion.

Two days prior to his death I was induced, from the peculiar features in the case, to suspect the presence of the ameba, and was kindly allowed by his physician to examine the dejecta. The discharge was obtained directly from the anal orifice upon sized paper, diluted with warm sterilized water, and examined with a moderately high power. The amebæ were observed in large numbers—from three to five in each field. During the two days before his death several examinations showed numbers of the animalcules present. They were of different sizes, the smaller being much the more animated. I also observed the so-called spores of Kartulis, the small, glistening bodies, with little or no motion, differing but little from the leucocytes present. I did not find the nucleated bodies of Kartulis.

The autopsy, three hours post-mortem, showed cadaveric rigidity not marked; hypostasis about the loins; the abdominal walls flaccid. A median incision revealed the contents of the abdominal cavity of normal appearance, with much fat about the meso-colon; the mesentery and its glands were normal; the intestine was tied at the duodenum and internal rectal sphincter, and placed in a water-bath for examination at leisure. The

upper duodenum was normal, and the ductus choledochus patent; the liver was slightly enlarged and fatty; the spleen was enlarged; the right kidney appeared normal to the eye, but the left had several retention-cysts and a thinned cortex. The lungs were normal, as were the pleuræ. The heart was infiltrated with fat. The stomach was normal. I examined the intestine carefully; the entire small gut was washed and minutely inspected, but, except for a slight catarrhal secretion, it was normal, though its contents were darkened from bismuth salts; there was not a single abrasion of the mucosa.

The diseased process commenced at the cecum, which was much inflamed, with hemorrhagic patches throughout its mucosa, besides a number of shallow ulcerations, and also a number of round openings or holes, as if made with a punch, leading beneath the mucosa into extensive undermined areas. These were intercommunicating, and at times led into the shallow ulcers. The mucosa covering such areas was in many places necrotic, and its débris was noted in some ulcers. Evidently the condition of round openings into the undermined areas was common to all the processes, and the ulcers had resulted from the necrosis of the mucosa above them. These round openings were quite small—about eight or ten millimeters in diameter. The open ulcers showed the muscular coat eroded and necrotic. The ascending colon was in the same condition; in the transverse, descending, and sigmoid colon there was more marked disease of the mucosa; the ulcers were more common, the round openings less so; the entire mucosa not necrotic was very edematous, and this edema extended to muscularis and serosa, which, though "juicy," were at no point penetrated. The mucosa presented a very similar likeness to the appearances seen in chronic cystic colitis, but incision through the edematous portions showed no dilated gland cysts. The contents of the colon were a slimy, yellowish fluid, in which were found numerous amebæ perfectly quiet, to which heating, with sterilized warm water, failed to restore motion. It would seem, then, that this condition of the mucosa is peculiar to amebic colitis, as has been advocated by Councilman. In no other case have I found just this type of undermined ulceration.

This case presents a source of infection quite similar to that found in cities along the banks of the Nile, in which the retention and storage of river water, from one high-water until the next, is depended upon for all household purposes. It is the habitual use of this reservoir-water that gives rise to the disease, and has named it "Nile dysentery." In Savannah, where the infection in the case reported was contracted, the city reservoirs were, until recently, supplied from the adjacent river, and at this time, I am credibly informed, many persons prefer to use the reservoir rather than the artesian supply.

The cases found in Baltimore by Dr. Osler were infected from surface wells, several cases having been traced to the use of water from the same well. In Charleston there are a number of such wells, and in this case the possible use of such water, which is infrequent, may have given rise to the disease, but the history seems to indicate the river-water as the source of origin. The cases reported from Cincinnati, where "river water," with its wealth of surface drainage, is still used, could possibly be traced to a like source. Thus it seems that the habitual use of surface-water from any source may be a means of transmitting the disease, but it is difficult to conceive that the animalcule could in safety reach the colon and establish its habitat there, unless the gastro-enteric tract were primarily diseased; and, although the ameba is deemed capable of inducing the changes noted in the mucosa coli under certain circumstances of gastro-enteric catarrh, and when injected into the lower bowel, as done by Kartulis, without this catarrh the infection does not seem to occur. Otherwise the disease would be much more frequent. From a study of this case, the animalcule does not seem to produce any product poisonous to the economy, nor to give rise to much pus-formation, therefore the leucocytes do not seem to be attracted by the cell-mass of the dead amebæ. Their influence seems solely mechanical; they gain entrance into the submucosa and destroy its cells. It is a process of necrosis rather than of inflammation that is the immediate result of their presence in the bowel. The course of the disease is chronic, and it usually lasts from six to eight weeks.

I am indebted to Dr. P. G. DeSaussure, the attending physician, and to Dr. B. E. Baker, resident, for their assistance.

PENETRATING WOUND OF THE BASE OF THE BRAIN THROUGH THE LEFT ORBIT—HEMIPLEGIA—REMOVAL OF CLOTS FROM THE BASE OF THE BRAIN—RECOVERY.[1]

BY ERNEST LAPLACE, M.D.,
PROFESSOR OF SURGERY AND PATHOLOGY IN THE MEDICO-CHIRURGICAL COLLEGE; SURGEON TO THE PHILADELPHIA HOSPITAL, ETC.

R. B., aged ten years, whilst at play on the lawn of his parents' country residence, fell on a broken fencing foil. The steel penetrated the left orbit between the inferior orbital ridge and the eyeball. The child was found a few moments later in an unconscious condition, with the instrument still in the wound. It was removed by a servant, and the child was placed in bed.

I saw the case about five hours after the accident. On ophthalmoscopic examination, the eyeball proper appeared uninjured.

There was coma, right hemiplegia, left facial paralysis, complete aphonia; the respirations were 30, the pulse 140, the temperature 104½°. Immediately above and about the center of the left orbital ridge was an incised wound about one-quarter of an inch wide, from which oozed a little blood. An exploration of the wound was determined upon. The patient was etherized, and the cutaneous wound was slightly enlarged. The handle of a Graefe cataract knife, inserted into the wound, sank almost by its own weight to a length of three and one-quarter inches into the wound, taking a direction toward the vertex and the middle line.

Inasmuch as no spiculæ of detached bone could be detected, the probability was that the instrument passed through the sphenoidal fissure, thence entering the base of the brain. The eye was apparently uninjured. There was, however, complete anesthesia. The pupil was dilated and insensible to light.

[1] Read before the Philadelphia County Medical Society, November 25, 1891.

Treatment by venesection, morphine, quinine, strychnine, and other stimulants not controlling the symptoms, thirteen days after the accident trephining was resorted to.

Operation. From the direction taken by the instrument it was evident that it had penetrated the middle fossa, and that hemorrhagic clots should be sought for in that locality. The patient being etherized, a horse-shoe incision, three inches long, was made in the temporal region, down to the level of the zygomatic arch, and the tissues were lifted *en masse* from the bone. The trephine was placed at the middle of the zygomatic arch, and a three-quarter inch segment removed, consisting of the temporal bone and a small fragment of the sphenoid; the dura mater appeared much congested.

To reach the center of the base of the brain for the removal of the suspected clot, a miniature egg-beater, consisting of four loops of platinum wire, had been improvised; this was perfectly malleable, and could be insinuated between the dura mater and the skull without wounding the cerebral structures. Having reached the cavernous groove the instrument could be pushed no further; it was then turned on its axis for the purpose of catching the coagula in its loops. This was effectually accomplished, and about a teaspoonful of clotted blood was removed piecemeal.

Whilst dragging more out, considerable venous hemorrhage took place, most probably as the result of the removal of the clot that had occluded the injured cavernous sinus.

The trephined opening was immediately plugged with iodoform gauze, and a graduated compress applied over it, secured by a tight bandage about the head.

The patient reacted well from the operation; consciousness gradually returned; movement was restored, and speech was resumed.

The improvement was steady and progressive. At the end of three months the patient could sit at table. A secondary plastic operation was performed to close the wound remaining.

Six months after the accident the patient had equal use of both inferior extremities. He was able to stand and to make a few steps without support. The pupil of the left eye was somewhat contracted. There remained anesthesia of the eye and internal strabismus, indicating the existence of an injury to the ophthalmic division of the fifth pair, which supplies sensation to the eye, and an injury to the sixth pair, which supplies the external rectus, thus corroborating the suspicion that the foil had penetrated the spenoidal fissure. The continued improvement warrants the hope of ultimate complete recovery.

REMARKS.—1. From the direction taken by the instrument producing the injury, it is probable that it passed through the sphenoidal fissure, wounded the cavernous sinus, the crus cerebri, and entered the left lateral ventricle.

2. The hemiplegia was due to venous hemorrhage and laceration of the crus cerebri and other structures, no spiculæ of bone being detected.

3. The coma, hemiplegia, aphonia, and progressively unfavorable course of the patient were relieved by trephining, low in the temporal fossa, lifting the brain, and removing blood-clots from the seat of hemorrhage.

4. The vast amount of oozing and secretion from the opening afforded evidence of the great intra-cranial tension and of the absolute necessity of drainage.

5. Consciousness returned shortly after the relief of the intra-cranial tension. Phonation and articulation soon followed.

6. The brain is situated in an unyielding box of the cranium, and, therefore, when exposed to great irritation, little allowance has been made by nature for the resulting expansion (congestion, swelling in other parts). With a view of remedying this condition, if the brain is not in a position to expand freely, as a result of the irritation, drainage should be provided for by trephining, which meets the indication by affording a point of least resistance to the tension within the calvarium.

This principle applies to many cerebral conditions in which symptoms of general compression result from local or general irritation within the cranial cavity. That this principle found a happy application in the present case is evidenced by the great serous exudation that daily permeated the dressings.

7. We wish to emphasize the safety of trephining near the base of the skull, the ease of arresting violent hemorrhage from the sinuses of the dura mater, and the importance of drainage in all cases of cerebral injury.

8. To our knowledge, there is no other recorded case of trephining as low in the temporal region, and removal of clots from the base of the brain.

NITRO-GLYCERIN.

BY C. S. STEWART, M.D.,
OF AMITE CITY, LA.

AN emergency remedy, to obtain the confidence of the physician, must possess the qualities of efficiency and promptness, so that when demands are made upon it the response will justify the confidence. There is one class of emergency cases in which promptness of relief constitutes the battle, and if this necessary relief is not to be had there is frequently a fatal termination. This is in the condition in which a weakened heart already exists and additional work is suddenly thrown upon it, or the tension is increased to such a degree that its work is seriously interfered with. Of the many remedies recommended for such a condition I have found none to act more promptly, reliably, and satisfactorily than does nitro-glycerin.

This agent has the general action of the nitrites in that it "lessens arterial tension and diminishes resistance," and possesses the advantage that its action is more persistent. This quality, according to Dr. Brunton, results because "the whole of it is absorbed without decomposition," and the nitrous acid free in the blood acts powerfully, relieving strain when rupture or fatal interference with function seems imminent.

After using nitro-glycerin for several months in a variety of cases, I am fully impressed with the idea of its importance, and rely upon it with as much confidence as I do upon older and better-known remedies. Three cases will fully illustrate my experience.

CASE I.—N. L., a Creole negro, about sixty years old, previously healthy, was stricken with right-sided hemiplegia, and when seen was speechless and helpless, with his heart as irregular as it was possible to be. Dissolu-

tion seemed imminent, as the extremities were cold, the features congested, and the heart seemed to have more to do than it could accomplish. Nitro-glycerin was administered hypodermatically, and in a very few moments its action was made manifest by an improvement that was continued.

CASE II.—C. L., white, about sixty-five years old, in feeble health, and subject to epileptic seizures, was taken with convulsions of unusual severity, and when seen was unconscious and covered with cold, clammy perspiration; the breathing was irregular and labored; the heart was irregular, the beats feeble and at times almost stopping; the extremeties were cold; and the pupils were insensible to light. Nitro-glycerin, supplemented by external and hypodermatically-administered stimulants, speedily aroused him from his seemingly hopeless condition, and consciousness was regained.

CASE III. will illustrate the beneficial effects of nitro-glycerin in cardiac and renal dyspnea. Mrs. G. was left in a damaged condition by the "grip," the heart bearing the brunt of the attack. Mitral and aortic murmurs were soon heard, followed by slight albuminuria. Matters continued with varying degrees of improvement for about six months, when every symptom seemed suddenly aggravated by unusual fatigue; edema of the extremities developed, until the legs were twice their usual size; there were very distressing dyspnea, great disturbance of the heart's action; fully 50 per cent. of albumin in urine; vision was impaired. The ophthalmoscope showed no retinitis, and there were very few casts in the urine. Among other remedies nitro-glycerin was used for its effect upon the cardiac dyspnea and for the condition of the kidneys, and with prompt relief. Cardiac tonics, diuretic mixtures, and nitro-glycerin were subsequently given with the happiest results.

Reports of the use of nitro-glycerin in asphyxia from coal-gas inhalation, and in threatened death from chloroform, have been sufficiently frequent to justify confidence, the results having been satisfactory and prompt.

In cases of nephritis accompanied by dyspnea, in which a weakened condition of the kidneys would contra-indicate the use of opium or morphine, nitro-glycerin will give prompt relief to a distressing symptom, and at the same time relieve the strain upon a diseased organ.

TRAUMATIC LACERATION OF THE URETHRA.

BY JOHN RODMAN, M.D.,
OF ABILENE, TEXAS.

MR. J. L., forty-five years old, was gored by a bull on October 25th. I saw him at 2 A.M. on the 27th. There was a wound in the perineum involving the structures between the bladder and the rectum. The urethra was so badly lacerated that a metallic catheter introduced into the penile portion was visible for one and a half inches. A slight amount of fecal matter and considerable flatus passed through the wound, the latter for five days.

The depth of the wound was quite two inches greater than the length of the fully-inserted index finger. The lacerated right lobe of the prostate could be distinctly seen.

Urine was passed through the fistula at noon on the 26th, subject to the control of the sphincter. After persistent and futile attempts to find the vesical extremity of the urethra, I was compelled to aspirate the bladder from above the pubes. This was repeated twice daily, until the 29th, when a dome trocar was left in position for two days; subsequently urination fortunately took place through the wound and has since so continued. The development of gangrene necessitated the removal of considerable perineal tissue. The wound is now suppurating freely, and is otherwise in good condition. Prior to my last visit I anticipated that I should be compelled to enter the bladder through the abdominal wall and pass through the urethra a Nélaton's catheter, with a window at the level of the urine and fastened in the abdominal wound, as it was all-important to secure drainage at the perineum without puncturing the bladder from below so as to avoid dribbling. This contingency was averted by the fortunate escape of urine through the perineum before my arrival.

Now the problem is, can the vesical and penile ends of the urethra be united? Will the wound heal over a catheter retained for the time necessary for the healing of such an extensive wound? Can I expect any better result than a perineal fistula with control of the discharge of urine? I think not.

[It would seem wise to introduce a catheter into the bladder and give the wound the opportunity to heal over the instrument. Whether the two ends of the urethra could be united by a plastic operation is a problem that could not be solved unless the patient were seen. If this is not possible and the patient had not control of the perineal fistula, the next best thing would be to open the bladder above the pubes and establish an oblique urethra in the abdominal wall.—ED.]

TRACHEOTOMY FOR A MELON-SEED IN THE TRACHEA.

BY L. HUFFAKER, M.D.,
OF DAISY, TENN.

A BOY, about three years old, while eating a piece of watermelon, became strangled, and sucked a seed into the trachea. The father brought him to me on July 7th for the purpose of having the seed removed. I located the seed as having passed below the vocal bands, and advised tracheotomy. Dr. Frank Trester Smith, of Chattanooga, performed the operation.

The patient was etherized, and an incision about one inch long was made in the integument. The sterno-thyroid and sterno-hyoid muscles were next separated from each other, and the cervical fascia and the thyroid plexus of veins were exposed. After controlling the hemorrhage, the trachea was opened from below upward for about three-quarters of an inch, and the seed removed. The incision in the trachea was then closed by one suture, and the incision in the integument was closed with four sutures; the wound was dressed and left for the night.

On the following morning I found some swelling, both internal and external. After bathing the parts well with carbolized water and Castile soap, I applied an ointment of vaselin and iodoform, prescribed a laxative, and directed a liquid diet. The temperature was about a degree above the normal.

On the morning of the 10th I found the patient suffering from considerable constitutional disturbance, the tempera-

ture being 2½° above the normal; the tongue was somewhat coated, and the bowels were constipated. I dressed the wound as before, and found granulations springing up. A laxative and some quinine were prescribed. On the morning of the 11th the temperature was about normal; the patient had rested very well during the night. I removed the dressing and found the wound suppurating nicely. I cleansed it again with carbolized water and Castile soap, and applied an ointment of iodoform, bismuth subnitrate, and vaselin.

On the morning of the 11th I removed the deep suture and dressed the wound as before.

On the 14th I removed two of the superficial sutures, and on the next day I removed the rest. I now discontinued the iodoform, and used as a dressing an ointment composed of bismuth subnitrate, vaselin, and carbolic acid, which I continued until I discharged the case on or about July 19th.

A CASE OF MALARIAL HYPERPYREXIA.

BY JAMES A. TURNER, M.D.,
OF LITTLE'S MILLS, N. C.

ON September 5, 1891, I was called to see a negro child about two and a half years old, living in an intensely malarial locality. I found the child with the muscles of the neck, trunk, and extremities in a state of rigidity, its eyes fixed and pupils dilated. At intervals of about thirty minutes, there were paroxysms of general convulsions, which would subside in about one minute, when the child would again lapse into the former condition in which it had been twelve hours. The parents stated that it had had chills for several days, and that the day previously it had several violent convulsions. I found the temperature in the axilla to be 106°, the pulse small, and so frequent that I could not correctly count it. Thinking the convulsive condition due to the hyperpyrexia, I applied cold cloths to the head and administered antipyrin hypodermatically, repeating it in thirty minutes, without any results. I then ordered the child to be placed in a tub of water just from the well, but owing to the small size of the tub and the rigid condition of the patient, I could only get it into the water to the knees. I therefore poured water from a vessel on its head, and in a short time it was sufficiently relaxed to be well covered with water, from which it was taken in eight minutes, sleeping soundly. It was dried and put to bed, the thermometer in the axilla showing a temperature of 101°. I gave calomel and quinine, and directed bromide of potash to be given through the night, and quinine in the morning. I called to see the patient on the following day, and found it in every way doing well, with the temperature normal. It was quite well in a few days.

RAT-TAIL SUTURES.

BY E. OLIVER BELT, M.D.,
OF WASHINGTON, D. C.

ABOUT five years ago, while resident physician in the Presbyterian Eye and Ear Hospital of Baltimore, I saw Dr. Chisolm uses fibers from the tail of an opossum for sutures in some of his eye-work. I thought such fibers a good substitute for silk, and spoke to my brother, Dr. A. M. Belt, about it. Shortly afterward a rat was caught at his residence; he had the tail skinned and soaked for several days in water, after which, upon slight manipulation, it separated into perhaps a hundred fibers, each about eight inches in length. These were placed in alcohol and presented to me, upon request, for use in eye surgery. I found the fibers strong and much finer than those from the opossum tail, or any other animal suture, and have been using them quite extensively in suturing the conjunctiva in pterygium operations, and in advancing the recti muscles in correcting strabismus.

These sutures have been most satisfactory. As soon as moist they become agreeably soft to the eye, and have never to be removed, while silk sutures are rough and irritating as long as they remain in the eye, and their removal is somewhat painful. Patients from a distance are often detained five or six days to have the silk stitches removed, when rat-tail sutures might be used and the patient allowed to depart immediately. These sutures will no doubt be found useful to the general surgeon and gynecologist when they need strong and fine animal sutures. About once a month, for two or three days, I soak the fibers in a corrosive sublimate solution (1 : 5000), and as I have never had any trouble whatever from their use, I think it probable that this suffices to render them aseptic.

ENUCLEATION WITH COCAINE.

BY JOHN L. DICKEY, M.D.,
OF WHEELING, W. VA.

I HAD a patient recently, a man aged forty, whose right eye had to be enucleated on account of a sloughing cornea resulting from an injury. As he had an organic heart disease I was afraid to use ether or chloroform. We proceeded slowly, dropping a four per cent. solution of cocaine from a pipette as we progressed, and within ten minutes succeeded in removing the ball with very little, if any, pain, and with the use of less than a dram of the cocaine solution. The patient showed none of the constitutional effects of cocaine, and made a rapid and satisfactory recovery.

MEDICAL PROGRESS.

The Treatment of Goiter by Enucleation.—LEHOTZKY (*Wiener klin. Wochenschr.*, Nos. 41 and 42, 1891) has tabulated sixty-two cases of enucleation of the thyroid gland, performed during six years at the clinic of Albert, at Vienna, partly on account of distressing symptoms occasioned by the goiter, and partly for cosmetic reasons.

In thirty-three cases the goiter was firm; six were in men, twenty-seven in women; the operation was successful in thirty-two; one case died.

The size of the nodules varied from that of a hazelnut to that of a man's fist. In one case the gland was as large as a child's head, and was suspected to be malignant, but the excessive size was found to be due to the presence of a cyst. The capsule of the gland was of varying thickness; in one case it was almost two inches thick. In most cases the limitations of the gland were well defined. Frequently there were band-like adhe-

sions, necessitating the employment of scissors, knife, and ligature. The most important and most dangerous element of the operation is hemorrhage. Slight capillary hemorrhage is the rule, even if the greatest care be exercised. In rapid operations the hemorrhage was always profuse; in such cases the wound was packed with iodoform-gauze and the vessels ligated. In all cases absolute hemostasis was secured. By ligating the various strands of adhesion before dividing them, and by treating the pedicle of the tumor in the same way, the operation may be made a bloodless one; but such a mode of procedure requires much time and more patience. In only one instance was parenchymatous hemorrhage encountered. Secondary hemorrhage occurred once. In one case the hemorrhage was so profuse that the carotids were exposed for ligature. In one case death resulted on the day after the operation, from the entrance of air into a ruptured vein; at the autopsy pneumonia and emphysema were found.

In twenty-nine cases the goiter was cystic; four were in men, twenty-five in women; in most of the cases (fifteen women) the patients were between twenty and thirty years old; the operation was successful without exception.

After division of the skin, one or more thin membranes were usually found; these were incised and the cyst dissected free; a true capsule was found only in cases in which there were also firm nodules or parenchymatous hypertrophy. Thin-walled cysts occasionally ruptured, discharging their contents over the field of operation. The removal of the empty cyst may be easy or difficult. In one case it was necessary to suture the cyst-wall and the skin; in another, to permit calcified, adherent portions to remain. The difficulty of the operation was increased when a portion of the cyst was seated behind the sternum. In one case, in which injections of iodine had been unsuccessfully made, enucleation was subsequently performed without difficulty. A suppurating cyst was successfully removed. Hemorrhage was, in general, less than in the enucleation of solid goiters, although in some cases it was profuse. In one case secondary hemorrhage occurred.

The enucleations were made with the assistance of chloroform-narcosis. In a number of cases of small tumors, local anesthesia induced by cocaine proved sufficient. Restlessness of the patient increased the difficulty of the operation. One death occurred from chloroform-narcosis following an enucleation easily and rapidly performed. The incision in the skin was made from above downward, over the most prominent portion of the tumor. Catgut was employed for ligatures, silk for sutures. When the enucleation was completed and hemostasis had been secured, a strip of iodoform-gauze was loosely laid in the wound, the extremity being brought out at the lower angle, and the skin was sutured. When the gauze was removed, the drainage canal was permitted to close by granulation.

The advantages claimed for the operation are: (1) that through a single wound several nodules or cysts may be removed; (2) that the recurrent laryngeal nerve is outside of the field of operation, and is exposed to no risk of injury; (3) that in many cases the operation is readily performed, and the course and result are satisfactory; (4) that sufficient glandular structure remains to afford assurance against the development of the cachexia strumipriva.

In cases in which the goiter was constituted of several divisions that included the entire gland, only those portions were removed that occasioned symptoms.

The Restoration of Defects in Tendons.—KÜMMEL (*Wiener medizin. Presse*, No. 43, 1891) has reported the case of a coachman who, while managing a pair of balky horses, perceived a sense of pressure, followed by severe transitory pain, involving the whole of the left arm. Shortly thereafter a swelling appeared in the region of the left wrist-joint, the functional activity of the hand, however, remaining unimpaired. Several hours later severe pain in the left arm appeared. The thumb hung limp, and could be neither adducted nor extended; it felt numb and cold. The injury was considered a luxation, and treated by means of applications of lead-water. At the end of three weeks there remained no doubt that the extensor pollicis longus had been ruptured. Upon opening the sheath of the tendon it was found that the central extremity had retracted to the middle of the forearm. The distal extremity lay rolled up on the metacarpal bone of the thumb. Attempts to approximate the two segments proving unsuccessful, the diastasis of almost four inches was supplied by moderately strong, twisted silk thread. The wound in the skin was closed and the extremity was dressed in hyperextension. The first change of dressings was made at the end of two weeks, the position of hyperextension being from time to time gradually relaxed. At the end of six weeks the splint was permanently removed, and movement was carefully instituted. In the course of four weeks more the patient was able to use the thumb with considerable force. The case demonstrates the possibility of replacing defects of tendons by non-vital structure, with restoration of function. It is possible that the silk threads furnish a guide and support for the connective tissue that is to replace the defect.

A Glioma of the Pons Varolii.—WILLIAMS (*Bristol Medico-Chir. Journ.*, September, 1891) has reported the case of a boy of six, who, it was observed, had become tiresome and fretful and manifested some awkwardness of gait, with a tendency to stumble and subsequently to rotate. The face was drawn a little to the right; the right eye presented convergent strabismus; the pupils were large and inactive; the left optic disc was blurred; the tongue was protruded in the median line; the knee-jerks were normal; the grasp was good and equal on both sides. No complaint of headache was made. The boy was restless during sleep, kicking off the bed-clothing. He was irritable and had outbursts of bad temper. There was no vomiting and no vertigo. Hearing was unimpaired. The urine had a specific gravity of 1030; it contained no albumin, but a trace of sugar. The symptoms progressively advanced; twitching of the muscles of the face appeared; paresis of the left side developed; vomiting occurred on two occasions; the muscles supplied by the right sixth nerve became paralyzed; the left knee-jerk became exaggerated. Death ultimately resulted amid the symptoms of exhaustion. At the autopsy the ventricles and the subarachnoid space were found distended with fluid. The pons was

the seat of a new growth that involved especially the right half. The crura were enlarged, the right crus especially. The third nerves were flattened. The sixth nerves were displaced, particularly the right nerve. On histologic examination the tumor proved to be a typical glioma.

Primary Scleroma of the Larynx.—JUFFINGER (*Wiener klin. Wochenschr.*, No. 41, 1891) has recorded the case of a girl, seven years old, who presented herself complaining of hoarseness, which, it was stated, had followed an attack of severe, persistent pain in the chest lasting three months, for a considerable portion of which the child was compelled to stay abed. Upon laryngoscopic examination, a tumor was found below the right vocal band, attached to the posterior wall of the larynx, and projecting forward and to the left, by its presence preventing the apposition of the vocal bands. The child disappeared from observation for nine months, finally returning on account of increasing dyspnea, with which aphonia was associated. The tumor had meanwhile undergone enlargement, and the lumen of the glottis was much obstructed. The surface of the tumor was smooth, its color pale-red, its consistence firmly elastic. A diagnosis of scleroma was confirmed by the results of bacteriologic and histologic examinations. No other abnormalities were found in the respiratory tract.

A second case of primary scleroma of the larynx was observed in a boy, thirteen years old, who, it was stated, had been hoarse for six months. Examination revealed the existence of so-called subvocal chorditis, the vocal bands presenting inferiorly great prominences that came in contact anteriorly, leaving but a small free space posteriorly.

Treatment of Myxedema by Means of Hypodermatic Injections of an Extract of the Thyroid Gland of a Sheep.—MURRAY (*British Medical Journal*, October 10, 1891) reports a case of myxedema in a woman forty-six years old, in which manifest improvement took place in the course of the subcutaneous administration of an extract prepared from the thyroid gland of a sheep. The thyroid gland of a sheep is removed immediately after the animal has been killed, and is separated from the surrounding connective tissue and fat. The gland is cut into small pieces and placed in a test-tube containing fifteen minims each of pure glycerin and of a 5 per cent. solution of carbolic acid. The mouth of the tube is closed by a plug of cotton-wool. The mixture is allowed to stand in a cool place for twenty-four hours, and is then expressed through fine linen or gauze. The extract obtained should be kept in a bottle with a glass stopper, and remains fresh for a week. Twenty-five minims may at first be injected twice weekly. Subsequently the injections, which are conveniently made into the loose connective tissue between the scapulæ, need not be made so frequently.

The Temperature of Epileptics.—Before the Congress of Mental Medicine, MAIRET and BOSE (*La Médecine Moderne*, No. 35, 1891) reported that as a result of a series of observations upon epileptics kept in bed, the temperature being taken every fifteen minutes, they had determined that the temperature undergoes no change in anticipation of a paroxysm. During the attack they were able to distinguish two periods: a convulsive and a stertorous. The former was attended with a lowering of the temperature if the seizure was a severe one; but, if the attack was mild, there was little alteration of the temperature. In the period of stertor the temperature rose three or four tenths of a degree, but this elevation was but relative, as the temperature was actually lower than the mean temperature on days on which no attacks occurred. After the attack the temperature returned to or exceeded slightly the normal. The mean temperature was a little higher on the days on which attacks occurred.

The Constitution of the Sweat.—From a study of the constitution of the secretion of the sudoriferous glands, GAUBE (*Comptes Rend. des Séances de la Soc. de Biol.*, November 6, 1891) has found that the sweat is of acid reaction in man, but alkaline in the horse, the cow, the dog, the cat, and the pig. Both in animals and in man the secretion contains albumin. The total amount of nitrogen in the sweat is greater than that represented by the contained urea; the excess is largely due to the presence of albumin and albuminoids. In man and in animals the sweat contains diastasic ferments, which are called hidrozymases. In man there are three—an amylase, a pepsin, and an emulsin; in the horse there are two: an amylase and an emulsin. The sweat of man contains little amylase, less pepsin, and still less emulsin; that of the horse and of several other animals contains less hidrozymases than does the sweat of man.

Endocarditis following Circumcision.—CZERNY (*Prager med. Wochenschr.*, No. 39, 1891) has reported the case of a child, of Israelitish parents, that was without antiseptic precautions circumcised on the fourteenth day after birth, and two weeks later presented restlessness, apparent difficulty of breathing, elevation of temperature, and loss of weight. On auscultation over the body of the heart, systolic and diastolic murmurs were heard, but the organ was not enlarged. The diastolic murmur subsequently disappeared and cardiac hypertrophy developed. Prior to the operation the heart had been auscultated, and no murmurs were heard; so that the etiological association between the operation and the endocarditis was quite clear.

Double Subacute Glaucoma.—Before the London Ophthalmological Society, CRITCHETT (*Lancet*, October 24, 1891) reported the case of a woman, twenty-nine years old, in which, within twenty-four hours after a severe shock, there was felt intense pain in both eyes, with vomiting and loss of vision. The eyes soon became densely hard, the pupils dilated, and the media so hazy as to interfere with a satisfactory view of the fundus. There was doubtful perception of light. The results of operative interference were not encouraging, and it was at the urgent solicitation of the patient and her mother that a double iridectomy was performed. The wounds healed favorably, but the recovery of vision was gradual and slight. The discs subsequently showed moderate cupping. At the end of fifteen years little further change had taken place.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment. When necessary to elucidate the text, illustrations will be provided without cost to the author.

Address the Editor: GEO. M. GOULD, M.D.,
1004 WALNUT STREET,
PHILADELPHIA.

Subscription Price, Including Postage in North America.

PER ANNUM, IN ADVANCE . . . . . $4.00.
SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,

PHILADELPHIA.

SATURDAY, DECEMBER 5, 1891.

SHOULD REPUTABLE PHYSICIANS ADVERTISE AND SHOULD MEDICAL JOURNALS PUBLISH THE ADVERTISEMENTS?

THE *Journal of the American Medical Association* prints the card of a physician, and in addition gives a generous and flattering editorial "reading-notice" of its patron.

This is the fact that every American physician has to look squarely in the face, estimate at its proper value, and decide what he is "going to do about it."

Of course, far worse things are every day being done by journals that by straining the English language may be called medical. Men eaten up with vanity and self-seeking may publish their own portraits, with uproariously laudatory autobiographical notices, may write or hire the writing of wonderful puffs—"reviews"—of their own books, may found societies, and elect themselves officers of the same, and all that. To such we have become habituated, as to the foul smells of dirty streets.

But the journals that do these things are not labelled "American" in an official sense, are not the official organs of supposed reputable medical societies, and do not claim for their advertisers anything more than good looks and personal popularity. Such things deceive only those that would be fooled by the portrait of the patent-medicine man and that see a logical connection between a man's picture and his therapeutic power, or that of his nostrum.

There is an apologetic tone about the *Journal's* "reading-notice" that apparently would excuse the advertisement on the ground that it is "only a plain professional card without puff, etc." One cannot help thinking of Thackeray's character, the girl that thought her mistake should be condoned because her illegitimate child was such a very, very small baby.

According to DR. GAINES's letter in the *Journal* there are at Hot Springs some seventeen regular and reputable physicians to some forty irregulars. In justice to themselves the remaining sixteen regulars must now insert their cards in the *Journal* or be out-generalled by the single one who has started the ball a-rolling and who receives the *Journal's* commendation. Moreover, the *Journal* must insert their cards; and, if just, must also give a eulogistic editorial "reading-notice" equally as long for each as for its first advertiser. On what grounds also can it exclude the irregulars? There are all degrees of irregularity. The insertion of the one "reading-notice" and card logically establishes the *Journal* as a self-constituted judge of reputability and regularity, unless it consents to take the advertisement of the out-and-out quack as well as that of the non-advertising physician. It would seem a strange logic that would permit the advertisements—"limited"—of the reputable and exclude those of the non-descripts and disreputable. That is giving away the whole cause and slipping the leash off the necks of the whole pack of would-be advertisers.

The affair aptly illustrates the danger that besets the question of the most limited of advertising, and also of the false ethics of the rule of doing evil that good may come, or of meeting the principleless advertiser with the weapons of his own forging. We do not mean to imply a word against the reputability of the single Hot Springs physician that has hired the advertising columns of the *Journal*. That is a question wholly irrelevant. But if one of the seventeen may or should insert his card with a "reading-notice" in one journal, the other sixteen should and must do the same, and not only in one medical journal, but in all. And if in medical, why not in the lay newspapers? And if only a card, why not the specialty? And if so much, why not a list of the cures, real or imagined? It is absolutely impossible to draw the line between limited and

unlimited advertising, or between advertising by an ethical-code-loving physician for a good purpose and by a sharper and a quack for his unlimited self-interest.

Moreover, every honorable physician in the land is waging a ceaseless struggle, often hard—and, because against secret enemies, often more hard—with quacks, and especially with the quacks inside the profession, who in sly ways are daily advertising themselves, but who are always careful to keep clear of the open methods that can be found out or proved. If the Hot Springs practitioner is logically right, or reluctantly forced by his beastly competition to advertise, so has each of us the same right and the same need.

The honorable physician at Hot Springs certainly has a hard lot; we sympathize with him most deeply and sincerely, but the way out of it all is not that unwisely inaugurated by the *Journal* and its advertiser.

TOTAL ABSTINENCE, OR THE MODERATE USE OF ALCOHOL?

ALL London, and indeed all England, has for several months been greatly excited over the outspoken advocacy by DR. J. MORTIMER GRANVILLE of the moderate use of alcohol. The newspapers have been filled with letters and articles from "all sorts and conditions of men" advocating with fervor every phase of opinion concerning the question—every phase except downright drunkenness. The numerous advocates of intoxication are too busy in translating theory into practice, and thus illustrating the possible genuineness and excellence of their creed, to theorize and write about it! The thesis of GRANVILLE is, in a word, that those that practise teetotalism are white-livered, cowardly, good-for-nothing, despicable beings, and that only the drinkers are the conquerors of nations, of ignorance, and of barbarism. He says:

"Abstinence, all the world over, and in all ages, has taken, and still takes, the backbone out of a man, and leaves him a limp, invertebrate animal with a pulpy brain, a feeble intelligence, and a will which lacks the power to assert its authority over the instincts and propensities it was made to control."

That this is an outrageously exaggerated and positively untruthful statement cannot be doubted by anyone that knows history or men and that judges dispassionately.

And yet that there is much justification for the essential basis of GRANVILLE'S crusade there can also be no denying. We all have in mind the ghastly nightmare of a theory lately hurled at the world by the great TOLSTOI. According to this psychologist alcohol and tobacco are the agents made use of by the inherently devilish will of man and of humanity to murder in self the voice of conscience and of God, and thus indirectly to license the unrestrained domination of innately evil appetites and desires. The world smiled pathetically or sardonically at the preposterously rabid exaggeration of the morbid Russian. And yet, again, despite the over-emphasis and the untruth, here too there is much that serves as a justifying and supporting basis of the theory. Those that deny it any logical or *de facto* value are, in a limited way, most probably practising on themselves the horrid game that TOLSTOI so vehemently describes.

There can be no blinking the patent fact that, as human nature is now constituted, men, many men, all too many men, cannot resist the temptation to use too much alcohol, if its free use be allowed and encouraged. Whether they will or not, the "moderate users" encourage themselves or others to become immoderate users. GRANVILLE and all those of his way of thinking forget or minimize this fact. They contend for the right of private judgment in a matter that, by fatal and fateful necessity, at once becomes public judgment.

He that loves his fellow-men will acknowledge the righteousness of the Pauline maxim that if meat maketh one's brethren to offend, then he should not eat meat.

This last farrago of nonsense, that only by drinking alcohol can one become strong in will and great in deed, is unqualifiedly false. It is logically a pure *non sequitur*. Power of character may or may not coëxist with the limited use of or total abstinence from alcohol. Had strength of character been dependent upon alcohol, the evolutionary forces of Nature, the Mind behind minds, would have offered man the finished food-product, instead of the grain and the fruit and the flesh so admirably perfected.

On the other hand, the total abstainers forget one important fact: an old justification of Catholic faith and tradition is founded on the motto, *Quod semper, quod ubique, et quod ab omnibus*—what has always, everywhere, and by all, been believed, must be true. There is a profound reason for the belief that the very widespread, if not universal, use of alcohol in

all ages and by all peoples corresponds to some deep need and use. A strong and universal appetite must have its *raison d'être* in some physiological utility, which neither the pathological degradations of drunkenness nor the heroic zealotry of prohibition can either wholly cancel, perfectly conceal, or effectually disprove.

In the exercise of their calling, in dealing with disease, physicians have no manner of doubt about istered with judgment and discrimination. With a the efficacy and therapeutic value of alcohol adminsingle eye to their patients' good, they will certainly continue so to advise its use.

But in a certain true, though limited, sense, senility is a pathological condition, and the sense in the justifiable, half-therapeutic, half-hygienic use of which it is pathological points the indication for alcohol. A very wise man put the rule into an apothegm, too sharply drawn indeed, but expressive of the physiological law: "No man should use alcohol before he is forty-five years of age; everyone should use it after this age." Is it not true that usually, and under normal circumstances and strains, Nature endows the young with such assimilative powers, such a capital stock of vital energy in the bank of organization, that up to an indefinite time in life the common foods are sufficiently powerful and assimilable to fit the body to cope with the severest tasks and the mind to fulfil the most exacting duties? Is it not also true that a time comes, usually between forty and fifty, when the reserve forces seem less spontaneous or so easily exhausted that the readily oxidizable food and hourishing stimulant that we call alcohol is not only useful, but quite often absolutely essential to the continued functions and demands? Does not this suggestion point to a harmonization of the views of the extremists, and to serviceable and rational use befitting discriminating and dispassionate minds, whether lay or professional?

THE PLACARDS AND EXHIBITIONS OF FREAKS AND MONSTROSITIES.

Popular exhibitions and liberally displayed advertisements of monstrosities raise the very pertinent inquiry as to the effect of such sights on unborn children. While there is a want of unanimity of opinion as to the exact manner in which monstrosities are produced, there is no reasonable doubt that certain powerful reflexes, causing strong emotions in the mother, may result in their production. It is to be said, however, that the element of active fear has generally been markedly present in cases in which the sight of a strange or terrible object has been followed by the birth of a deformed child. A notable instance of this sort was found in the person of the "Elephant Man," who has been the rounds of the London hospitals: while visiting a menagerie his mother was greatly terrified by an elephant, which seemed about to attack her; at birth the infant's face resembled that of an elephant, and his skin presented some of the characteristics of the animal's hide. So shocking is his appearance that he is debarred from any occupation, and subsists upon the charity of the various hospitals.

Monstrosities most often result from a visual reflex, the terrifying object or occurrence having been seen; they may also develop when emotions of fear or grief have been excited by the description of a horrible object, or the narration of a fearful occurrence. Thus, in the observation of the writer, a mother who was shocked by hearing that a friend had been thrown from his horse against a dray and had his skull fractured, gave birth to a child that presented red sensitive areas upon the scalp, corresponding in location with the fracture of the skull in the person whose death had so alarmed the mother. In the *British Medical Journal* of September 19th there is an account of a case in which a pregnant woman, having been shocked by seeing four children, all of one parent, affected with talipes varus, gave birth later to twins, each of which presented double talipes varus. The *Medical Mirror* of November, 1891, reports a strange case of entire absence of the calvarium in a child, the mother of which had a conviction that the child would be thus deformed, because while pregnant she had been deeply impressed by a picture in a phrenological book showing the brain with the skull removed.

The question whether seeing a picture of such a monstrosity as Laloo would influence an unborn child cannot be categorically answered for all cases. There are women who would look upon such illustrations without emotion, while others would be shocked and terrified. There is no doubt that there is sufficient warrant for the belief in the power of hideous sights, through maternal impressions, to affect the fetus, and that the outrageous placards of the dime-museum freaks and monsters should be regulated or forbidden. The exhibition of such monstrosities to miscellaneous audiences should not be permitted, while scientific men should

be given the fullest opportunity of investigation. In general, it is doubtless true that those sights and occurrences that threaten the mother's safety and cause intense fear are those that are most influential in producing monstrosities. Among these, actual or threatened attacks by animals are especially potent, the monster resembling the animal that frightened the mother. A similar effect, less in degree, may be produced by the narration of a terrible occurrence or by the description of a hideous object. An interesting application of a belief in the potency of visual and auditory impressions during pregnancy to affect the fetus is afforded by the usages of the ancient Greeks, who were wont to surround the pregnant woman by such environment as should through sight and hearing give access to the brain of agreeable sensations only. The perfection of form that characterized the youth of ancient Greece bears witness to the influence of visual impressions upon the unborn child.

CORRESPONDENCE.

"WASHINGTON AS A MEETING-PLACE."

To the Editor of THE MEDICAL NEWS,

SIR: In your issue of November 14th will be found a letter from Dr. S. Weir Mitchell on the subject of the prevalence of diarrhea at Washington, D. C., during the session of the Medical and Surgical Congress which adjourned on the 25th of September last. Dr. Mitchell mentions the fact that the same epidemic influence was present at Deer Park, Md., and also at Newport, R. I., both of which places he visited immediately after the adjournment of the Congress. With equal propriety he might have called attention to other localities in the North and West, where it prevailed at the same time.

He advocates Washington as the proper and only place where this Congress should hold its sessions; and rightly so, because this is a national organization, and the Capital of the country is the most appropriate place for its triennial sessions.

The charge against the water of that city, of being the cause of the diarrhea from which so many suffered during the session of the last Congress, is not sustained by facts. It just so happened that at the time the Congress was in session, from the 22d to the 25th of September, there was an unprecedented spell of hot weather—verily *a heated term*—which extended all over the North and Northwest: a spell of weather unlike any before experienced at that season of the year. Was not this heat a potent factor in causing the bowel affections, which were not to be found in Washington alone? As a proof that the water was not the cause, we can cite the fact that the American Surgical Association has held its annual sessions in that city since April, 1884. I have attended each and all of its sessions, and I have never heard that its Fellows have been made ill by the water. The American Medical Association held its session of 1884 and also its session of 1891 in that city; the Ninth International Congress met there at its last meeting in America; and several of the special associations, especially the Association of American Physicians, have assembled there for several years, yet none of these Associations has ever before objected to the water as unhealthy or productive of diarrhea. It is true that in 1888, when our Congress held its first meeting in that city, there was some complaint of diarrhea and bowel troubles—but that year, as this, was noted for its very warm weather late in September. Imprudence in diet was as much at the bottom of the bowel troubles as the water drunk.

Our last Congress is conceded by all who were present to have been a most brilliant meeting, one which will yield an abundant harvest of rich scientific results. Washington City is one of the most beautiful on the continent; well paved and thoroughly drained; interspersed with large parks, which purify the atmosphere and render it attractive as well as healthful. It is a city of residences, rather than a busy mart of commerce; it is a center of social refinement and destined to become the focus of intellectual and scientific work in the Western Hemisphere. This being true, it is the proper and only place where this Congress should meet. Composed, as this Congress is, of the representative leaders of medical thought in America, it is likely to exert a powerful influence upon American medicine and surgery, and should hold its sessions at the National Capital. Since objections have been raised to its meeting in September, all obstacles can and will be removed by holding its triennial sessions either in May or June, when all will agree that the weather is especially delightful in that city.

There is not much danger of the Congress being destroyed by the water of Washington.

I am, very truly,
CLAUDIUS H. MASTIN.

MOBILE, November 16, 1891.

TOXIC EFFECTS OF ATROPINE.

To the Editor of THE MEDICAL NEWS,

SIR: A year ago a son of mine, a young man of twenty-three, went to St. Louis to study dentistry. Having some ametropia, he consulted an oculist, who for diagnostic purposes directed him for a few days to instil into the eyes a solution of atropine (gr. iv to ℥j). After a number of instillations, toxic symptoms manifested themselves. The boy became delirious and at times lost his way in going from place to place. There were also febrile symptoms. The mental disturbance lasted for several weeks. At the end of six weeks the young man was sent home, when it was found that he was suffering with small recurrent abscesses of one of the external auditory canals, which gave him much distress for probably two or three weeks from the time of their first appearance. Following this, he slowly and gradually improved and now appears well. His improvement was at times, however, marked by such irritability of temper that I suspected some mental derangement. His memory, which before was excellent, was much impaired for a number of months, and now seems not so good as formerly.

Applying recently for life insurance, his application was rejected by the medical director on account of the history of atropine-poisoning.

The action of the medical director was based upon an unusually unfavorable experience with cases of atropine-poisoning, an abstract of which accompanies this letter. Respectfully,

VIRGIL MCDAVITT.

VIRGIL MCDAVITT, M.D., Quincy, Ill.

MY DEAR DOCTOR: In answer to your letter, I will say that my experience in atropine-poisoning is unquestionably an unusual one.

My first case was in a child about six years old, poisoned by eating the seeds of the deadly nightshade. It was a severe case, although it rallied from the first effects; still there seemed to result a derangement of the digestive organs from which the child never recovered. It remained comparatively well for some two years and a half, dying apparently from the more acute attack of gastritis.

My second case was in a man, about forty years old, who had a severe attack of iritis. He was under treatment and had a solution of atropine to drop in the eye occasionally. By mistake he took an overdose by the mouth and in a short time was in the peculiar condition of one who has been poisoned by this drug. After some days of delirium he recovered so far as to be considered out of danger. The iritis continued a number of weeks longer, but it was finally recovered from. From that time, however, he had occasional attacks of delirium, and was finally so broken down mentally and physically that it became necessary to send him to an insane asylum, in which he died after the lapse of a year and a half or two years.

My third case was in a woman about thirty-five years old, with some uterine disorder, in the treatment of which an ointment of belladonna was applied to the internal surface of the uterus. After the application, vision became decidedly impaired; the woman staggered, and was finally carried home from the street in this condition. For some days the symptoms were alarming, but under treatment the woman rallied, and at the end of two weeks seemed to have recovered. She was, however, never as strong as before the accident, and suffered frequently from alarming attacks of hysteria; her physical health failed, and in about three or four years she died.

My fourth case was in a man, over sixty years old, who by mistake took a large dose of atropine, supposing it to be a preparation left by his physician to quiet the pain of neuralgia from which he was suffering. He became delirious very soon afterward, and in the course of from a half to three-quarters of an hour profoundly comatose. By the use of the stomach-pump and other measures he rallied, after lying in an unconscious condition for some two and a half hours, and in the course of a week or ten days, although he was weak, he was apparently free of the effects of the poison. He never fully recovered, but lived for some three and a half years, dying of apoplexy. After having taken the poison he was never quite as clear in his mind as before.

These are the cases to which I referred. I have never observed a case of severe poisoning from the application of atropine to the eye. The case of the woman referred to may, perhaps, belong in the same class, as it was one of poisoning by absorption from the mucous membrane of the uterus and vagina. I have never observed a case followed by abscesses of the auditory canal.

I know of no antidote for the effects or after-effects of poisoning by atropine. Opium antagonizes the primary effects, although I do not believe that the poisonous effect of the atropine is overcome by the opiate; neither do I believe atropine to be an antidote in opium-poisoning. I have always felt that the best we can do for the after-effects of atropine-poisoning is to treat the patient on general principles, trying as much as possible to overcome the debility and mental agitation by the usual mode of treatment. Very truly yours,

THOS. A. FOSTER.

WORMS IN THE AUDITORY MEATUS.

To the Editor of THE MEDICAL NEWS,

SIR: In THE MEDICAL NEWS of November 21st I notice a communication from Dr. James Mitchell, concerning "Worms in the Auditory Meatus," that recalls to my mind the following case. While attending lectures at the Bellevue Hospital Medical College, New York, in 1878, a patient was brought into the lecture-room suffering from some sort of ear trouble. Professor Alexander B. Mott was the physician-in-charge. The patient was a male, white, about thirty, and evidently belonged to the lower walks of life. On being questioned by Professor Mott as to his ailment, he replied that he suffered from pain in one of his ears, and that in addition there was at times hemorrhage from the ear. These symptoms had been present during several weeks.

The lecturer took an ordinary ear-speculum, and in the meatus saw something that brought to his face a mingled expression of surprise and disgust. Still holding in place the speculum, with a light pair of dressing-forceps he picked out worms from the patient's auditory meatus, and laid them on the table. I do not recall the number, but there were certainly as many as six or seven, each about from three to six lines in length, and from half a line to perhaps a line in thickness. They were not of a perfectly white color, but of a brownish-white.

On questioning the patient as to his occupation, he replied that he was employed in a flouring-mill, and that every day he had been in the habit of lying down on top of a wheat-bin, during his "nooning," and sleeping for half an hour or longer. The lecturer thought the worms must have been weevils—or some other insect of this nature—from the grain underneath the sleeper, and ova deposited therein.

C. A. JOHNSTON.

HOPBOTTOM, PA.

NEW MEXICO AS A HEALTH RESORT.

To the Editor of THE MEDICAL NEWS,

SIR: The medical world has been reluctantly forced to turn its eyes from the German laboratories again to hygienic, supporting, and especially climatic treatment for chronic pulmonary diseases. It is admitted by intelligent observers that climate is the first factor in the successful

treatment of all chronic lesions of the broncho-pulmonary tract. At this opportune period let us have a more thorough and accurate knowledge of the climate of our own country. To this end we offer some brief observations on the climate of New Mexico, especially of that part of the Territory in the vicinity of Albuquerque. As the American Health Resort Association has reported favorably on Albuquerque as the location for its sanitarium for patients suffering from chronic pulmonary diseases, a few observations by a resident practitioner of this city may be of interest. Why New Mexico as a health resort has previously occupied such a limited space in American works on climatology is hard for the physician to understand who has personally experienced the dry, bracing, delightfully salubrious air of its valleys, table-lands, and mountains, and has seen its effects upon patients. With ten thousand inhabitants, Albuquerque is five thousand feet above sea-level, on the left bank of the Rio Grande, extending from the valley proper to the high table-land. It is twelve miles from mountains that are from seven to nine thousand feet high, issuing from the bases and cañons of which are a series of mineral springs, which in variety and quantity of medicinal ingredients will compare favorably with those of any springs of the same area on the continent. North of the city, extending from thirty-five to eighty miles, is another series of mineral springs, the waters of which cover a wide range of ingredients, the waters of some of which are thermal, others cold. The waters from some of these springs are bottled and shipped to some extent, though not so much as their virtues warrant. The waters from many of these springs, in which the natural senses detect strong medicinal properties, have never been analyzed. Coyote springs, Sandia Mountains, New Mexico, the waters of which are bottled and shipped in considerable quantities, show by analysis the following ingredients:

Iron carbonate	13.
Magnesium bicarbonate . . .	13.4
Calcium bicarbonate . . .	48.6
Sodium sulphate	14.
Sodium bicarbonate . . .	6.25
Sodium chloride	58.6
Total in one gallon . .	153.85

The rainfall here is comparatively light, most of the precipitation being in August and September. We never have a day in which the sun does not shine, and during the daytime I have never seen four consecutive hours during which the sun was hid.

The winters in this part of New Mexico are seldom colder than is the weather in the months of October and November in the Middle and Eastern States. The editor of one of our daily journals told me that he had never had a fire in the editorial or composing room of his office during any of the five or six winters that he has been publishing his paper in Albuquerque. The mornings, evenings, and nights are always cool, but seldom, even in winter, is there need of fire from 10 A.M. to 4 P.M.

A striking illustration of the beneficial effect of this climate is to be found in conversing with residents. Many of our busiest and best business men came to Albuquerque as invalids.

We would summarize our observations as to the class of cases that in this climate improve or recover health, and *vice versâ*, as follows:

First. Patients with dulness in any part of the pulmonary tissues, and who are troubled with morning cough and expectoration, but who have no rise of temperature, and have not yet begun to lose weight perceptibly, do well.

Second. Patients with more diffused consolidation, with considerable constitutional disturbance, but not yet presenting cavities, are benefited or recover.

Third. Hemorrhagic cases—that is, patients who from the beginning have had slight hemorrhages, without any fever-reaction or profound constitutional disturbance—do extremely well in these altitudes. Contrary to former teachings, patients seem to be less liable to hemoptysis here than at sea-level. This does not refer to the rupture of large vessels in cavities in advanced disease.

Fourth. Patients in whom the disease is advanced, having cavities and severe febrile symptoms, are better at home; certainly so if they are ill enough to be confined to their rooms. Especially is this true of those who have not abundant pecuniary resources.

Fifth. For patients recovering from attacks of acute pleurisy and pneumonia, and having a tuberculous diathesis, an altitude such as ours is the place *par excellence*. The increased number of respirations invigorates, and the light, dry, ozonized atmosphere enters the collapsed air-cells, and acts beneficially upon the depressed and devitalized system. Patients with advanced throat or laryngeal involvement should seek lower altitudes, the moist atmosphere of Southern California, *e. g.*, being more suitable.

Sixth. Very high altitudes are, of course, known to be unsuitable for rheumatism; but at this altitude of only five thousand feet, cases of both acute and chronic rheumatism are very amenable to treatment, unless the heart-complications are severe, which apparently is not more likely to be the case than in the Mississippi Valley.

Very truly yours, W. G. HOPE.

ALBUQUERQUE, NEW MEXICO.

NEWS ITEMS.

Dr. Adolph Schauenstein, ordinary professor of State Medicine at Gratz, recently died at the age of sixty-four years.

A Medical Faculty at Constantinople.—It is announced that a faculty of medicine is to be founded at Constantinople—the first in Turkey.

Ernst Fleischl von Markow, professor extraordinary of physiology in the High School of Vienna, and for many years the assistant of Brücke, recently died, at the age of forty-five, of the sequelæ of a dissecting-wound acquired in the duties of prosector to the chair of pathological anatomy. In addition to minor papers he was the author of monographs upon normal and pathological histology, general neuro-pathology, physiological optics, the law of contraction, and the relation of the heart-beat to respiration.

THE BACILLUS COLI COMMUNIS: THE CONDITIONS OF ITS INVASION OF THE HUMAN BODY, AND ITS PATHOGENIC PROPERTIES.[1]

BY WILLIAM H. WELCH, M.D.,
PROFESSOR OF PATHOLOGY IN THE JOHNS HOPKINS UNIVERSITY, BALTIMORE, MD.

WE owe especially to Escherich the knowledge that certain species of bacteria are regularly found in the healthy intestinal canal. Of the bacteria present in the normal feces the most abundant is the bacillus coli communis, first described by Escherich in 1885, under the name bacterium coli commune.

This bacillus presents so many points of resemblance to the typhoid bacillus that Rodet and G. Roux contend that the latter is simply a variety or modified form of the colon bacillus. There are, however, so many points of difference between these two bacilli that they must be regarded as distinct species. The typhoid bacillus is actively motile, the colon bacillus only feebly motile; the typhoid bacillus never coagulates milk, the colon bacillus coagulates it in two to seven days; the typhoid bacillus does not cause fermentation of lactose, or if at all, only in very feeble degree, while the colon bacillus actively ferments lactose. There are also differences in the appearances of the growth of the two bacilli on gelatin, agar and potato, but these are less precise and constant than the points mentioned.

Escherich demonstrated that injections of bouillon cultures of the colon bacillus into the circulation of guinea-pigs and rabbits are capable of killing the animals by acute intoxication, if sufficient quantity is injected. Smaller quantities he believed to be devoid of pathogenic power. Dr. Blachstein has published the results of a series of experiments made in my laboratory, showing that injections of one c.c., or even less, of bouillon cultures of the colon bacillus into the ear-veins of rabbits may cause the death of the animals as late as six weeks after the inoculation. These rabbits were much wasted, and presented peculiar changes in the liver and bile. The bile contained the colon bacilli in large number, at a time when they had disappeared from the blood and organs. It was thin and pale, devoid of the normal green color, and presented particles of bile pigment, necrotic epithelium, and masses of bacilli. The liver often contained necrotic foci; the spleen was atrophied.

The first observation of the colon bacillus in the tissues of the human body outside of the intestinal canal was made in 1889 by Tavel, who found this organism in the wound resulting from removal of a tumor of the thyroid gland. Since then there have been several observations of this bacillus associated with peritonitis, angio-cholitis, and some other affections. Observations of this invasion of the colon bacillus have been made by Wyss, Laruelle, Gilbert and Girode, Charrin and Roger, Naunyn, A. Fränkel, and Malvoz. Bönnecken has found the colon bacillus in the fluid of strangulated hernial sacs.

No systematic observations, however, have been published as to the frequency and conditions of invasion of this bacillus into the tissues of the human body. I have for about a year and a half been interested in observations of this character, and take this opportunity to present the most important of the results.

My first observation was in April, 1890. The case was one of acute hemorrhagic pancreatitis, with multiple fat-necroses in the meso-colon and omentum. The bile was nearly colorless, and presented a sediment containing yellow, granular bile pigment, cylindrical epithelium, and zoöglea of bacilli, reminding one of the changes in the bile observed in rabbits dying a long time after intra-venous inoculation with the colon bacilli. There existed a very acute diphtheritic colitis with superficial ulceration. In this case pure cultures of the colon bacillus were obtained from the foci of fat-necrosis, the mesenteric glands, the liver, the bile, the lungs, the spleen, and the kidneys. In this, as in all the cases, roll agar and gelatin cultures were made after thoroughly burning with a hot knife the surface of the organ at the point where the sterilized needle was inserted. The autopsy was made within one hour after death, and in general the autopsies were made in less than twelve hours after death. The colon bacillus, moreover, is not one of the bacilli that invades organs after death in the process of post-mortem decomposition.

As in this case diphtheritic and ulcerative colitis

[1] Abstract of the address of the President of the Medical and Chirurgical Faculty of Maryland, at the semi-annual meeting of this society in Rockville, Md., November 17, 1891.

existed, it seemed probable that it was the lesion of the intestinal mucosa that permitted the invasion of the colon bacillus. From this time we have made bacteriological examinations in the manner described in most of our autopsies.

We have now found the colon bacillus in one or more of the organs of the body in thirty-three autopsies out of about two hundred. (There followed in the address a brief description of these cases. Here only a summary of the principal results is given.)

The suspicion at first entertained has been abundantly confirmed, namely, that lesions of the mucous membrane of the intestine open the way for the invasion of the colon bacillus into the blood and lymphatic vessels, and thence into various organs and parts of the body. The lesion consisted in different cases of hemorrhage, ulceration, perforation, catarrhal and diphtheritic inflammation, strangulation, cancer, traumatic injury, and intestinal suture.

The bacilli were found in the blood, lungs, spleen, kidneys, peritoneum, bile-ducts, gall-bladder, liver, lymphatic glands, testicle, tonsil, brain, and wounds, varying in their distribution and number in different cases. They were found with especial frequency in the lungs and kidneys, but often also in the liver, mesenteric glands, and spleen. The number of colonies in an original tube varied from one or two to a countless number. The diagnosis of colon bacillus was never made without applying all necessary tests, and especially never without demonstrating the power of coagulating milk.

It is not to be inferred that ulceration or other lesion of the intestinal mucous membrane is necessarily associated with the invasion of the colon bacilli in sufficient number to be demonstrable by ordinary culture methods, but only that such invasion is a frequent result of the lesion.

In a number of cases colon bacilli were demonstrated by culture methods in various organs of the body without any noteworthy lesions of the organs containing them or any lesion that could reasonably be referred to their presence. This was true, for instance, in several cases of amebic dysentery. On microscopical examination the bacilli, often in clumps, readily staining with aniline dyes and even with hematoxylin, could be demonstrated inside of small bloodvessels without any alteration in the surrounding tissues. There is, therefore, no evidence that in these cases the bacilli do any harm, although it cannot be positively stated that their presence is innocuous. It is well known that human blood-serum outside of the body exerts a powerful germicidal influence upon the colon bacillus.

This class of cases, therefore, in which this bacillus appears to be a harmless invader, should make one cautious in attributing pathogenic powers to the colon bacillus, even when it is associated with definite lesions, unless it can be shown that other causes can be excluded. In the case of fat-necrosis, for instance, I do not believe that the colon bacillus was the cause of the necrosis, although both cultures and cover-slip preparations showed its presence in large number. I have subsequently made bacteriological examination of three cases of multiple fat-necrosis without finding any microörganisms in the necrotic foci.

I have suspected that the colon bacillus may be the cause of lobular pneumonia, as in several cases this organism has been found in large number and in pure culture in congested, edematous, and inflamed areas in the lungs. It has also been frequently associated with fatty degeneration of the kidneys, but neither in this nor in the pulmonary affection is there any conclusive evidence that the presence of the bacilli has done the harm.

The view that the changes in the bile noted in the case of pancreatitis already cited are referable to the colon bacillus, rests upon experimental evidence. In two cases of angio-cholitis and cholecystitis with gall-stones, the colon bacillus was very abundant, and in pure culture, in the bile. Naunyn has recently called attention to the possible relation between the formation of gall-stones in some cases and the growth of this bacillus in the biliary passages. Gilbert and Girode, as well as Charrin and Roger, refer cases of suppurative inflammation of the bile-ducts and gall-bladder to the penetration into these parts of the colon bacillus.

In cases of peritonitis due to perforation of the intestine the colon bacillus is usually found, but not always, in large number in the exudate, sometimes in pure culture. In three cases of peritonitis due to intestinal ulceration without perforation I found the colon bacillus in large number and in pure culture. The exudate was sero-fibrinous, not distinctly purulent. In these cases it seems warrantable to attribute the peritonitis to the invasion of the colon bacillus into the peritoneal cavity. In a case of ruptured tubal pregnancy the bloody fluid withdrawn by a sterilized hypodermatic syringe from the peritoneal cavity before laparotomy was performed, yielded a pure culture of the colon bacillus. There was found a perforative appendicitis. In the pus of circumscribed abscesses due to perforation of the vermiform appendix I have found the colon bacillus in nearly pure culture. It is a mistake, however, to say, as Malvoz has recently done, that all cases of peritonitis due to intestinal lesion are referable to the colon bacillus. Often enough in this class of cases the staphylococcus pyogenes aureus or the streptococcus pyogenes is present—it may be predominantly so—in the peritoneum. In a case of perforative appendi-

citis recently examined the streptococcus pyogenes seemed to be the only organism present.

In a case of ovarian abscess adherent to an ulcerated cancer of the rectum the colon bacillus was found in pure culture in the abscess.

To the occasional presence of the colon bacillus in laparotomy wounds for the extirpation of diseased Fallopian tubes and ovaries, I have already called attention on another occasion.

It is especially important to know that typhoid ulceration of the intestine opens the way for the invasion of the colon bacillus, which may be found in the mesenteric glands, lungs, liver, kidneys, and elsewhere, mixed with the typhoid bacillus. On account of the resemblance between these two species of bacilli a mistake might easily be made in identifying the colon with the typhoid bacillus, and there is reason to believe that this mistake has been made by some writers. The preservation of all its properties in these cases shows that the colon bacillus is not changed into the typhoid bacillus when it invades the organs in typhoid fever; and this is a further argument against the unwarrantable assumption of Rodet and G. Roux already mentioned.

Only in two cases have I found the colon bacillus in organs outside of the intestine without any demonstrated lesion of the alimentary canal. Although careful search was made, it is not improbable that some lesion was present, so small or of such a character as to escape observation with the naked eye.

A FEW OBSERVATIONS ON THE MYDRIATIC ALKALOIDS.

By ROBERTS BARTHOLOW, M.D.,
of Philadelphia.

The editor of The Medical News has had an intimation from some of his readers that they desire to have some recent information on the subject of the mydriatic alkaloids, and in accordance with his suggestion, I shall seek briefly to satisfy the want.

It may be best to present a tabular statement of the source and names of the principal members of the group:

Mydriatics.

Atropine—Alkaloid of Atropa belladonna.
Salts of atropine:
Atropinæ sulphas;
" hydrochloras;
" hydrobromas;
" salicylas.

Atropine is supposed to be a compound alkaloid and made up of *tropeïn* and *tropic acid.*

Homatropine—A synthetical product formed by the combination of tropeïn with amygdalic acid.

Hyoscyamine—Alkaloid of Hyoscyamus niger.

Hyoscine—Alkaloid of Hyoscyamus niger; and also a synthetic or derivative alkaloid.
Salts of hyoscine:
Hyoscinæ sulphas;
" salicylas; etc.

Duboisine—Alkaloid of Duboisia myoporoides; like the others, one of the Solanaceæ.
Salts of duboisine:
Duboisinæ sulphas;
" hydrochloras.

Solanine—Alkaloid of Solanum tuberosum; the unripe fruit.

Daturine—Alkaloid of Datura stramonium.

According to Ladenburg, daturine, duboisine, and atropine are isomeric and in every way identical with hyoscyamine in chemical constitution and physiological action. If any deviation is found to exist, it is assumed to be due to a modification of the molecular arrangement and not to any fundamental change in the nature of these substances. How far molecular arrangement, and how far substitution, may modify the original powers of the medicament is a question of extraordinary interest. The first experimental work done on this subject was conceived and carried on by Prof. Fraser and Dr. Crum-Brown, of the University of Edinburgh.

They demonstrated that by substituting *ethyl* and *methyl* molecules for some of the existing molecules, the result was that the tetanizer strychnine was converted into methyl-strychnium or ethyl-strychnium, which is a paralyzer like conium or curara in respect of its action on the cord, yet in respect of its chemical relations it reacts to the same tests as strychnine. There occurred, therefore, such a substitution of molecules, that the physiological characters were changed, yet chemically the reactions were not changed.

These remarkable experiences have led to some happy combinations through molecular substitution. We owe to Prof. Ladenburg a series of important investigations, giving new light on the subject of the mydriatic alkaloids. He has shown that atropine—so long before the medical profession as a single alkaloid—is really a compound body, and is made up of *tropeïn* and *tropic acid.* By combining amygdalic acid with tropine a new synthetic product results, and is known as *homatropine.* Now homatropine has actions corresponding to atropine, and is chemically and physically similar, but the effect exerted by it differs much in degree, but not so much in kind, from its progenitor.

Homatropine is preferred to atropine for various ophthalmic purposes, chiefly because its effects on the pupil and the apparatus of accomodation are, while as complete, much shorter in duration. As

a derivative agent, therefore, as a piece of upbuilding of molecules, it has proved satisfactory.

As respects its power and range of utility, *hyoscine* is the most important of the group, and as respects the function of mydriasis it is equal to atropine, homatropine, and duboisine. The qualities that make the range of utility of hyoscine so great are its hypnotic, antispasmodic, and anesthetic powers. Hyoscyamine, its cogener, with its pain-relieving, sleep-producing, and antispasmodic properties, has had much reputation for the relief of certain kinds of nervous diseases. Of the two forms in which it is found in commerce, the amorphous seems to be the more active and curative. Hyoscyamine has visibly declined in reputation since the introduction of hyoscine, owing to the greater certainty and power of the latter. In asylum practice hyoscine has largely supplanted morphine in the treatment of acute mania, the violence of acute melancholia and of general paresis, and as a hypnotic in general. It is remarkable for the absence of after unpleasant results, such as headache, nausea, and constipation, which follow the administration of morphine and other similar agents of the narcotic group. The most experienced therapeutists have agreed on two facts of great importance as to its use, *e. g.*, as to the dose most serviceable in cases of cerebral disease requiring an anodyne; and as to muscular activity—unrest, agitation, etc., as a factor in the therapeutical diagnosis.

It has been shown by various authorities that the minimum dose is, as a rule, far more useful than massive doses, and that intense muscular activity is a condition indicating the use of such a narcotic. The dose of hyoscyamin ranges from $\frac{1}{200}$ to $\frac{1}{10}$ of a grain, and of hyoscine from $\frac{1}{300}$ to $\frac{1}{100}$. Both act favorably when given hypodermatically, and in almost all instances not more than two doses per day will be required. In suitable cases, after the administration of small doses, the sleep is quiet, refreshing, and the system remains free from the after-headache, nausea, hebetude of mind, and constipation that follow in the wake of opium and other narcotics frequently administered. It has been observed that when a dose is administered larger than that merely sufficient to cause sleep, the sleep is apt to be accompanied by jactitations, dreams, and considerable uncontrolled mental agitation. If, however, the amount given is merely adequate to cause sleep, but sleep without disturbance, the result is far happier in the condition of the mind and body.

The action of hyoscine on the muscular system is one of the purposes for which it is now much used, and by those having the largest opportunities for judging, successfully used. My personal experience is decidedly in favor of its administration in cases of *senile trembling*, *paralysis agitans* and *fibrillary agitation* In cases of *chorea*, and of various spasmodic affections of the nervous and respiratory systems, it has a useful place as a remedy.

I should not close this paper without saying something of the remarkable powers of duboisine in mental maladies of a certain kind. I have seen cases of puerperal mania yield to this when all other means had failed. It is far more effective when given by subcutaneous injection than in any other manner. The minimum dose may be given as $\frac{1}{100}$ of a grain, whilst the maximum should not exceed $\frac{1}{60}$ of a grain for adults. Although by Ladenburg considered identical with hyoscyamine, it is clear that it is not identical with it in therapeutical action. Patients experience sensations of a different kind when experiments of control are made or when trial doses are exhibited, and the objective evidences are clearly different. No chemical analysis can dispose of such facts nor can molecular modifications of structure explain the essential differences in physiological and therapeutical actions.

If I were asked to indicate where my preference lay in selecting a mydriatic for maladies mentioned below, my reply would be as follows:

For eye operations and refraction-work, homatropine.

For the treatment of eye-inflammations, atropine.

For maladies attended with insomnia, neuralgia, nervousness, various kinds of nervous trembling, as chorea, senile trembling, paralysis agitans, muscular agitation and unrest, hyoscine or hyoscyamine.

For mental diseases of a depressing kind, melancholia, etc., puerperal mania, with or without albuminuria, duboisine, hyoscine, or hyoscyamine, but especially the first named.

For acute mania, paranoia, mental disorders with much muscular agitation and frequent and protracted muscular restlessness, hyoscine or dubosine.

STRICTURE OF THE URETHRA AND ITS TREATMENT.[1]

BY L. BOLTON BANGS, M.D.,
PROFESSOR OF GENITO-URINARY DISEASES IN THE NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL; SURGEON TO ST. LUKE'S AND CHARITY HOSPITALS.

IT may not be necessary to give a definition of the pathological condition called stricture of the urethra; but, in order that, in speaking of treatment, I may be clearly understood, and that, in using the word stricture, my meaning may not be misapprehended, I would like to define stricture of the urethra as any unnatural narrowing of the urethra in any part of its whole length. At various times attempts have been made to demonstrate the normal

[1] Read at the meeting of the American Association of Andrology and Syphilology, held in Washington, September, 1891.

urethra as a "closed valvular chink," with certain natural or physiological widenings and narrowings in different parts of it. It seems to me that the canal should be looked upon as a living organ, supplied with muscles and nerves for the two physiological purposes of taking away from the body the urine, and of ejecting the seminal fluid. Anything in the canal, therefore, that will interfere with the proper performance of these duties, or that irritates the nerve-relations, disturbs the harmony of the organ and must be regarded as pathological or unnatural. Whether it be deformity resulting from imperfect pre-natal development or the result of post-natal disease, it occupies the same place in relation to the natural conditions of the organ. It is, then, manifest that to arrive at a clear conception of an obstructed urethra its normal state must be appreciated, and, therefore, each urethra must be studied by itself.

When a large number of urethræ are examined and compared with each other, it will be found that they all present one characteristic, not only in adults but also in infants, namely, that the portion described by anatomists as the bulbous portion is the largest in caliber, or, in other words, capable of the greatest degree of physiological distention. What the precise object of this is I am not prepared to state, but it undoubtedly has some physiological purpose in relation to the function of the urethra. From its position, shape, and muscular contractility it has seemed to me that it serves as a sort of machine for duplicating or reinforcing the action of the bladder and posterior urethra in ejecting the normal fluids. It is evidently not to be regarded as determining the caliber of the spongy portion of the urethra, for it narrows gradually (though in some individuals suddenly) to the commencement of the spongy portion, which is the barrel part, so to speak, and *its* size is the *caliber* of that urethra. Although efforts have been made to describe narrowings of the urethra in its penile portion as natural contractions, and therefore not strictures, because they are frequently found at or near the same point, from a careful study of a great many urethræ I am compelled to conclude that when present these narrowings are actually, practically, strictures in the sense in which the term is defined. In this I am confirmed by the results of treatment. Moreover, these narrowings are not found in every individual, nor in enough persons to form a rule. Over and over again I have examined urethræ that presented no narrowing of the slightest degree after the urethrometer had left the bulbous urethra and the normal physiological distensibility of the penile urethra had been determned. For example, we will suppose that the index of the urethrometer in the bulbous urethra points to the figures forty. At this number the instrument is withdrawn, say from an inch to an inch and a half, gradually being turned downward till the hand on the dial-plate indicates 32 Fr., when it is withdrawn smoothly, easily, and painlessly until it reaches the meatus, where we will say, for example, it is necessary to turn it down to 30, 28, 26, or 24, as the case may be. This urethra, then, I would regard as a normal one, provided, of course, that the posterior urethra was also found to be free from stricture. On the other hand, I have examined large numbers of patients, and have found a narrowing of varying degree in the situation claimed to be normal, say at a point two and a half or three inches from the meatus; having incised this band I have observed the symptoms to disappear, or have been enabled to cure a persistent gleet that, prior to the operation, had resisted all forms of treatment. Was this band normal or abnormal? I regard it as abnormal, and to be classed among strictures of large caliber.

Since the vigorous enunciations of Dr. Otis I think there is no difference of opinion in the minds of most genito-urinary surgeons that there is a class of strictures, chiefly to be found in the penile urethra, known as strictures of large caliber—that is to say, varying in size from 18 Fr. and upward, anything below that being classified as strictures of small caliber; and the latter may, of course, vary from the size named down to filiform, or even impassable strictures. Under some conditions of vigorous contractile quality, or under some condition of urethral irritation, strictures of large caliber may become of small caliber, and hence it is important that they should be recognized; but the majority of them rarely show a tendency to much contraction. When they give rise to symptoms, these are usually indicative of an irritant either to the mucous membrane, producing and maintaining catarrh; or to the nerves, producing various symptoms, direct or indirect.

Of course, many with stricture of large caliber may go to their graves without ever developing any symptom requiring treatment; and conversely, there may be men with symptoms of stricture of large caliber, who may have those symptoms relieved by other means than by operating upon the stricture. But by what factors is the immunity of the latter happy individual to be determined? I know of no other answer than by the good judgment that comes from large experience and careful examination of each case. Not only must the normal size of the urethra and the relative degree of contraction be determined, together with the effect of the latter upon the function of the urethra and bladder, but the pathological status of the mucous membrane must be ascertained by ocular inspection.

How important then that all fixed, arbitrary standards should be discarded, and that each urethra

should be considered and studied by itself. I, therefore, reaffirm my belief in the proportionate relation of the human urethra to the size of the penis in which it is contained, and of the necessity that only by recognizing this principle formulated by Dr. Otis can we determine how to give radical and humane treatment for an infirmity that concerns so many.

The degree to which a stricture will ultimately obstruct the urethra or interfere with its function is determined not merely by the amount of cicatricial contractile deposit caused by the original urethritis, but by the degree in which this deposit acts as an irritant to the urethral tissues. This may be learned, I think, by observation and by the results of treatment. By bearing it in mind we are enabled to make a stronger argument in favor of that means of intervention which, while it aims to relieve or cure the stricture, will irritate the fabric of the urethra in the least degree. For instance, I have seen within the urethra a nodule as large and as abruptly defined as a hazelnut, that had persisted for nearly two years, notwithstanding electrolysis and gradual dilatation, but which was entirely relieved and finally disappeared absolutely after one incision by internal urethrotomy. The deduction seems to me to be plain that the stricture began and the treatment itself kept up a sort of chronic inflammation that maintained and augmented the size of this nodule. After thorough division of the stricture, and maintenance of the separation of its sundered extremities, the functions of the urethra were performed easily, less nutriment was required by the tissues, and the abnormal growth ceased.

The part of the surgeon is not only to divide the strictures, but so far as possible to restore the healthy function of the organs. My convictions in regard to treatment may be briefly stated.

As a witness of the effects of divulsion, in regard to which considerable has of late been written, I cannot but withhold my belief in its advantages. The effect of the operation is an unknown quantity. The operator does not exactly know what he is doing. The effect of the instrument is distributed more or less beyond the strictured areas, and the resulting cicatrix is an irregular and oftentimes violently contracting one. It is non-surgical, non-scientific.

Electrolysis may be dismissed in a few words. When a current is used of sufficient strength to have any effect upon the tissues at all it acts as an irritant, produces inflammatory deposits, and the subsequent condition of that patient is worse than the first. I have had numerous patients coming to me with nodular strictures who had submitted to operations by the disciples of electrolysis and the strictures were exceedingly difficult of treatment.

Gradual dilatation is sufficient for soft, non-fibrous strictures of the posterior urethra and of those of similar pathological structure in the bulbous urethra. It is also sufficient in some of the soft, not well organized strictures in the penile urethra that are practically but simple *adhesions* (?) of the surfaces of the mucous membranes; but for organized strictures I believe that some form of urethrotomy is preferable.

For all strictures of large caliber *requiring interference* I advocate treatment by internal urethrotomy and thorough division, with as little cutting as possible, by means of an instrument that fixes and makes tense the stricture-tissue. The subject of strictures of small caliber demands closer differentiation. For simple, uncomplicated strictures, internal urethrotomy as already described is the remedy. If, however, the stricture be complicated by fistulæ, either in the penile urethra or in the perineum, or if there be indurated cicatricial deposits posterior to four and and a half inches, I would advocate external perineal urethrotomy in conjunction with internal urethrotomy. The former serves more than one purpose. It enables us to divide all stricture-tissue thoroughly and fearlessly, with a definite object in view, and enables us at the same time to abrogate the functions of the diseased urethra by draining away the urine, drop by drop, without any effort on the part of the urethra or perineal muscles. Thus physiological rest to the whole region is obtained as certainly as we obtain physiological rest for a broken limb when we put it on a splint. The process of healing is rendered a continuous and uninterrupted physiological one, without at any time becoming an inflammatory or disease process. Even in cases that have enormous, hypertrophic, indurated masses in the perineum, scrotum, and neighboring tissues—masses that are the result of tight or filiform strictures in the bulbous or membranous urethra—the effect of this drainage will be seen in the softening and gradual disappearance of these hypertrophies, sometimes before the perineal wound has begun to heal.

It seems to me that this principle of external and internal urethrotomy, combined with prolonged perineal drainage, holds good even in cases in which there are evidences of commencing renal degeneration. The result of my experience is that, when I have been obliged to take the responsibility of operating upon patients with tight strictures of the urethra, whose kidneys were in a condition of degenertion, these organs have been immediately relieved of a certain amount of "back-pressure," so to speak. They have resumed their function, as manifested by the diminution of albumin, the disappearance of casts, and by the improved general well-being of the patient. Nor do I think that the life of the patient

has been in the least degree jeopardized by the procedure indicated. On the contrary, patients whose existence would have been placed in peril by the slower process of gradual dilatation, have from the commencement of the perineal drainage shown evidences of rapid recuperation of health. The condition of the patient under these circumstances is certainly rendered perilous by the delay that of necessity is associated with the slower method. The danger is in the condition of the patient antecedent to the operation, or in the conditions that necessitate its performance, not in the operation itself.

ABSCESSES IN POTT'S DISEASE.

BY HERBERT L. BURRELL, M.D.,

SURGEON TO THE CHILDREN'S HOSPITAL, THE CARNEY HOSPITAL, AND ASSISTANT VISITING SURGEON TO THE BOSTON CITY HOSPITAL; INSTRUCTOR IN CLINICAL SURGERY, HARVARD UNIVERSITY.

IN this paper I shall limit myself to certain points in the course and treatment of Pott's abscesses that have occurred to me. An abscess, appearing in the course of the treatment of a case of spinal caries, is one of those incidents that may be considered as a conservative act of Nature in ridding itself of the detritus of a destructive process in the bodies of the vertebræ.

The symptoms vary according to the location of the abscess. With all cases there are at first associated a rise in temperature more or less persistent, loss of flesh, and particular individual symptoms according to the anatomical structures involved—for instance, dyspnea or dysphagia in retro-pharyngeal abscesses; respiratory symptoms in cervical abscess; pulmonary symptoms in upper dorsal caries; and in lower dorsal and lumbar abscesses, symptoms are developed according to the viscera pressed upon or involved. For the early recognition of abscesses I have come to depend largely upon a continued loss of appetite, loss of flesh, and continued elevation of temperature; in fact, when a child has been efficiently treated by mechanical support for the spinal caries, and for some reason is not gaining in general health, one may suspect that there is an abscess forming. In the adult, however, these symptoms are not common. Here the course of abscesses connected with spinal caries is quite different. One of the most remarkable things is the quantity of pus that may collect in a psoas abscess in an apparently healthy adult, who has but little intimation that there is spinal caries; perhaps all that has been noticed has been persistent lumbago until the patient is brought to the surgeon, who finds that the iliac fossa is filled with a resistant mass, the thigh slightly flexed and enlarged from the passage downward of the pus along the course of the psoas and iliacus muscles.

I have, in fact, come to regard spinal caries in an adult as essentially a different disease from that which occurs in a child. In adults the following group of symptoms is not at all uncommon: For a few months the patient has noticed some slight, persistent, local pain in the back, which is thought to be rheumatism. He experiences a sensation of general debility; there is slight loss of appetite, but he continues about his occupation—frequently a very laborious one, with progressive loss of flesh and persistent elevation of temperature. On physical examination no deformity in the spine can be determined, and occasionally, especially in the lumbar region, there is only slight spasm of the erector spinæ muscles; but in the iliac fossa, and down on the thigh, one may notice a large collection of pus. It is true that we may have spinal caries in a child appear very insidiously; but in an adult it is the rule, rather than the exception.

Although the appearance of an abscess in Pott's disease may be considered simply an incident of the disease, yet it is a very serious affair unless it is properly treated, and in many of our patients, in spite of all our care, it is the beginning of the end; for when an abscess opens, and sepsis occurs, unless great care is taken a fatal ending is inevitable.

The pertinent question in regard to all abscesses connected with spinal caries is: What shall be done with them? Shall they be left alone, and if so, how long? Shall they be opened, and if so, when? Formerly, as we know, these abscesses were left alone, because the mortality attending their opening was very great, but in later years we have come to regard the opening of abscesses in Pott's disease as a proper procedure under certain circumstances—and these circumstances I shall attempt to define. The surgical axiom, that wherever pus is found it should be evacuated, is not in this instance literally true, since we are all familiar with cases of abscesses in Pott's disease, that, left to themselves, and under careful mechanical and hygienic management, have in course of time become absorbed. It is true that reasoning from an individual case is, as a rule, dangerous, but I wish to relate one case that illustrates the expectant treatment of an abscess.

In 1884, an adult, J. D., twenty-four years of age, a bank-clerk in Somerville, was seen; he had been treated for a year or more for lumbago and rheumatism, but a few weeks previously he had noticed that his right thigh was enlarged and the limb flexed. He called the attention of his family physician to this, and I was asked to see the patient. On examination I found slight tenderness over the last dorsal and first lumbar vertebræ. The concavity of the right iliac fossa was filled with a dense, indistinctly fluctuating tumor. The right thigh, an inch below the groin, was six inches larger than the left, and was occupied by a fluctuating tumor. The

patient had lost some flesh, though his appetite was excellent, but he had been progressively growing worse. His condition having been explained to him, he concluded to try an efficient mechanical support for his back, and to temporize in the treatment of the abscess. A Taylor back-brace was adjusted, and the patient was instructed how to bandage the thigh with a flannel bandage to prevent the extension of the pus.

I saw this patient at various intervals during the next two years, and at the end of that time I could not detect any perceptible enlargement of the right thigh. Four years later there remained some thickening in the right iliac fossa, but the abscess had apparently been completely absorbed. At the present time he is engaged in his occupation, strong, and apparently perfectly well.

This is a case showing what can be done by expectancy. I could cite numerous instances of conditions practically similar in children that were strong and healthy, and not of a marked tuberculous diathesis, in which absorption of the abscess had occurred.

Bearing upon expectancy is the fact that these abscesses are often of long standing—that is, five, six or seven years may have elapsed since the beginning of the carious process; and the more quiescent the carious process, the better the result that may be expected from an operation.

Efficient mechanical support of the spine will in a great many cases unquestionably avoid the necessity for operative interference. My own feeling in regard to the matter is, that, until some failure begins in the patient's general condition, no operation should be thought of just so long as the patient is improving under efficient mechanical support to the spine, unless the abscess is extending in such a way that it is involving important parts—for instance, in the spine, the cord; in the thorax, the lung.

It seems far better to me to temporize until we feel assured that the abscess will not be cared for by absorption; and, again, when we do interfere, I believe in interfering most radically and efficiently; for the danger of interference in psoas abscesses is unquestionably from sepsis, and if we drain efficiently and thoroughly, and keep our wound free from septic contamination, we shall in the vast majority of cases have favorable results.

Aspiration of the abscess is an uncertain measure, for it rarely evacuates the abscess completely, because of plugging of the needle. It should be reserved for those few instances in which temporizing is being carried out, and relief to tension of the abscess is thought necessary.

The treatment by injection of the abscess-cavity after aspiration is uncertain, and when active germicides are used there is danger of systemic poisoning.

The ordinary psoas abscess, as it presents itself, forms a tumor in the iliac fossa and in the upper part of the thigh, and when expectancy has been tried and is of no further avail, I carefully prepare the patient for operation by accurately fitting a Taylor brace, or by recumbency in bed for a week or ten days. This, I have found, tends to limit the size of the abscess and to render it more readily drainable. After aspiration, to exclude the possibility of aneurism or solid tumor, a free incision, just external to the femoral vessels, is made into the substance of the presenting tumor. This is usually associated with the discharge of a large quantity of pus. An incision is then made into the most prominent portion of the swelling in the iliac fossa, care being taken that the peritoneum is avoided when one reaches the transversalis fascia and the subperitoneal fat. From this point a block-tin sound is passed as far as may be up into the abscess-track toward the spine. Direct drainage is then obtained by carefully dissecting down on the outer edge of the quadratus lumborum to the distended psoas and iliacus sheath. Usually these three openings are necessary in order to efficiently deal with the tuberculous material lining the abscess-wall. A curette and flushing are used freely, and large drainage-tubes are placed in such positions that they will efficiently drain the cavity. The incision in the iliac fossa is frequently closed by suture. Occasionally the incision into the anterior upper portion of the thigh is closed by suture, but rarely have I diminished the size of the opening which is made in the loin, from the fact that from this opening I hope to obtain direct drainage of the abscess from as near its source as is practicable. Of course, the fingers are introduced into the opening through the loin, and if any loose fragments of necrotic bone can be felt they are removed.

If the patient has a double psoas abscess I deal with both in the same manner, especially if they occur in an adult; because I have found that with double psoas abscesses it is better to drain both sides efficiently than to attempt to drain one side and then to drain the other; for, if only one side is drained, a large reservoir of pus may be left, which communicates through a small opening with the side drained, and this collection of pus is occasionally the source of systemic poisoning. If a psoas abscess is efficiently drained, the quantity of pus discharged will diminish from day to day, and, according to the size and extent of the spinal carious process, will gradually cease in a varying time.

No more depressing picture can be presented to a surgeon than to see a psoas abscess that he has opened become septic, and the patient gradually develop septicemia and die from that cause. Hence, for success in dealing with these abscesses, the most rigid antisepsis is absolutely essential.

Those unique abscesses, that for some reason do not follow the usual course, of descending in the sheath of the psoas muscle, but point posteriorly at some point on the back, are likewise dealt with by free incisions at their most prominent part, by efficient flushing, and thorough curetting.

Retro-pharyngeal abscesses, which are rare, form a group by themselves. I have seen only six, and two have been fatal. In both instances death occurred from bursting of the abscess and flooding of the lungs. Usually on introducing the finger into the posterior wall of the pharynx one can feel an elastic swelling, which may be incised by a suitably guarded knife introduced into the median line of the posterior wall of the pharynx. The "Roser position" of the head, that is, the head dependent over the end of a table, is by all odds the best, as, with a suitable mouth-gag, it gives complete and efficient control of the mouth of the patient, and the discharge of pus that takes place. With the patient in this position and efficiently held by assistants, one does not have to make a plunge in the dark, so to speak, but can thoroughly open the mouth, and can make a free incision directly into the apex of the tumor, and the discharge of pus will take place through the mouth and nostrils, and there will be no danger of suffocation from the pus entering the respiratory tract.

In the last two cases of retro-pharyngeal abscesses that I have had to deal with I made a direct incision just posterior to the right sterno-cleido-mastoid, dissecting down deliberately until I came in contact with the sheath of the main vessels of the neck. Holding these anteriorly I then entered a director or blunt probe, carefully separating the structures until I tapped the abscess laterally. In this manner I was in one instance enabled to keep the abscess sweet from beginning to end; in the other, unfortunately, the child was moribund at the time of attempting the operative interference, and my efforts were unavailing. This is a measure seemingly worthy of attention, and has been the subject of investigation by one Russian authority.

It is true that the operation for a Pott's abscess is a matter of consequence, but the dressing is of equal importance. I have come to use baked gauze, the inner layers of which are saturated with 1 : 2000 solution of corrosive sublimate, applied directly in contact with the various incisions that have been made. Over this is placed a large quantity of dry baked gauze; and I have found that assistants err in putting on too small a dressing. If it is a psoas abscess it is held in position by an efficient gauze spica-bandage. In all children great care should be taken to protect the dressing by putting on a mackintosh or oil-silk to prevent soiling by urine or feces. Usually, within twelve hours, this dressing must be changed; for from a cavity as large as the average psoas abscess an enormous quantity of sanious fluid drains away and saturates the dressing. When treated by this method the subsequent dressings remain sweet and clean for from a week to ten days at a time.

In abscesses that point in other regions than along the course of the psoas and iliac muscles, for instance on the back, where it is impossible to get directly to the bottom of the channel of pus, the cavity is tamponed with antiseptic gauze. In a retro-pharyngeal abscess when an incision is made directly behind the sterno-mastoid muscle, and the abscess-cavity is drained through this channel, a suitably-sized drainage-tube is placed in the wound, the remainder being held open by antiseptic gauze. This wound should be dressed once in twelve hours, owing to the liability of pus to collect in small pockets, and to prevent any possibility of pressure being made on the important structures of the neck. This measure should be carried out for two or three days.

In the prognosis of psoas abscesses there is an important distinction to be made between abscesses occurring early and late in the disease. In those early or *acute* abscesses that come on within the first few months of a caries of the spine, and that are associated with marked constitutional disturbance, the prognosis is not so favorable as in the late or *chronic* abscesses that occur in the disease, at the end of two, three, or more years, after the beginning of the carious process.

In acute abscesses the patient frequently succumbs to the disease in spite of all our tentative or operative efforts, whereas in chronic abscesses their evacuation by efficient drainage is simply an incident in the course of the disease.

Quite a large proportion of the cases that I have operated on for abscess in Pott's disease have recovered completely, but after a long period of time. There frequently persists for weeks and months, and in certain instances for years, a sinus, out of which is discharged a slight quantity of pus or straw-colored fluid. Frequently the mistake is made of leaving off the antiseptic dressing when the wound is reduced to this sinus, but it should be continued until all discharge has ceased. The drainage-tube should be retained until practically all of the tuberculous material has been discharged, although occasionally I feel that the tube is retained too long.

From my personal experience the following conclusions are warranted:

1. That efficient mechanical support of the spine is the prime factor in the treatment of caries of the spine associated with an abscess.

2. That under an expectant plan of treatment, the abscess will in many cases disappear.

3. That the indication for operative interference

is a steady or rapid decline in the patient's general condition.

4. That the operation should consist in thorough evacuation of the abscess, and the establishment of drainage from as near the seat of the disease as is practicable.

A CASE OF ACUTE GLANDERS OR FARCY.

BY CARL FRESE, M.D., L.S.A.,
PHYSICIAN TO MARY DREXEL HOME AND CHILDREN'S HOSPITAL; CHIEF RESIDENT PHYSICIAN IN THE GERMAN HOSPITAL, PHILADELPHIA;
AND
GEO. G. ROSS, M.D.,
RESIDENT PHYSICIAN IN THE GERMAN HOSPITAL;
AND
W. J. WILBERT, PH.G.,
APOTHECARY TO THE GERMAN HOSPITAL.

B. F. S., twenty-nine years of age, single, white, and by occupation a driver, was admitted to the hospital September 1st. His father died of pleurisy. The mother, one brother, and one sister are alive and well. The patient had always been a healthy man until six days prior to his admission to the hospital, at about which time he noticed that his right shoulder was painful and distinctly reddened. He could not remember having injured the part. He sought medical advice: a diagnosis of erysipelas was given, and iodine applied. The reddening, however, gradually increased and the part grew more painful, until at the time of his admission it had involved the anterior and posterior surfaces of the shoulder and the side of the neck.

The eruption, at this time, was erythematous, without vesicles, not punctate or marginate, but very painful. There was considerable tension about the parts and some fluctuation. The temperature constantly rose higher each morning. The evening temperature ran along the 105° line. The pulse was quick and full; the bowels constipated, with complete anorexia. The heart, liver, lungs, spleen, and kidneys failed to show any signs of organic disease. An exploratory incision into the inflamed area demonstrated the presence of but little pus.

The condition of the man grew steadily worse until, on the 8th of September, a small abscess formed at the angle of the jaw upon the right side. This single abscess was quickly followed by others, until, in the three days before his death, the entire cutaneous surface was covered. Abscesses appeared on the scalp, on the eyelids, in the nose and mouth—in fact, the palmar surfaces of the hands and the plantar surfaces of the feet were the only places exempted. These abscesses appeared first as an erythematous patch, from ¼ to ⅝ of an inch in diameter, quickly becoming indurated and soon breaking down, forming, near the center, a small pustule, which contained a single drop of pus. The pustule, when opened, disclosed at the bottom a grayish, tenacious and adherent slough, which involved more tissue than the size of the pustule would have indicated. On the scalp several pustules were so close together that when they broke down they formed a single ulcer, with this same peculiar slough at the bottom, discharging a thin, irritating, almost colorless fluid. The discharge from the nose was offensive and irritating. The irritation, which, beyond doubt, was due to these abscesses, involved the entire mucous membrane, because the discharge was as copious from the posterior nares as it was from the anterior. He constantly "hawked" and coughed, and complained bitterly of the difficulty in swallowing and the impairment of respiration.

He was at times quite conscious, but he more often displayed a mild and talkative delirium. Occasionally he tried to get out of bed, and it was thought wise to confine him; urine was constantly passed in the bed. A typical typhoid condition developed, with the dry tongue, weak, feeble, and rapid pulse, with a high temperature, which was but little influenced by antipyretics (quinine and phenacetin). He was fed and medicated by the rectum alone during the last two days of his life, owing to the total inability to swallow.

The treatment was simply symptomatic, and consisted mainly in the administration of large amounts of stimulants and quinine in large doses. He died on September 11th.

The post-mortem examination briefly showed the following:

The heart was normal, containing chicken-fat clots, evidencing the slow death. The lungs were the seat of many secondary abscesses, indiscriminately distributed and bearing marked similarity to those upon the external surfaces.

Macroscopically nothing abnormal could be discovered about the liver. The spleen was enlarged and was so friable as to be easily broken by the fingers.

The kidneys were normal.

In fact, the autopsy showed the only signs of secondary infection to be confined to the lungs.

We give the bacteriological examination of this case somewhat in detail. It was the means of verifying the clinical diagnosis, and it also shows the comparative simplicity of experimentally proving the identity of the virulent microörganism concerned.

On September 6th, by means of a sterilized Pravaz syringe, a few drops of serous fluid were obtained from the infra-clavicular region on the right side. A hanging drop examined by means of a Leitz oil-immersion $\frac{1}{12}$, ocular 4, showed moderate numbers of bacilli of about the size of tubercle bacilli. On attempting to stain cover-glass preparations with phenol-fuchsin, Löffler's blue, and gentian-violet, it was found that the bacilli did not take the stains readily, and it was only on leaving specimens in phenol-fuchsin for twenty-four hours, washing with distilled water, without after-treatment with alcohol, that fair coloring was obtained. The microscopical examination again showed bacilli, which appeared to be fully four or five times as long as wide, and in size closely resembling tubercle bacilli.

From the serous fluid, cultures were on September

6th made in beef-extract-peptone-gelatin, on beef-extract-peptone-agar-agar, and in a mixture of the two, which seems to answer admirably for cultures that are to be developed in the incubator.

The result was that in the course of three days, in the gelatin tubes, at the temperature of about 25° C., there was a decided development of small, white colonies in the line of the inoculating-needle, and near the surface, which in the course of twenty-four hours assumed a characteristic, delicate, stellate form.

This growth extended very slowly, and after a month showed a whitish surface of the non-liquefied gelatin, in the center of which, at the point of inoculation, was situated a black irregular mass. The agar-agar colonies, after three days, appeared as very small punctiform masses, growing very slowly, and not giving rise to any color. The gelatin-agar-agar colonies grew similarly to those in gelatin, with stellate arrangement, but without the black mass in the center, as noticed in the gelatin.

Successive cultures from these, both at 25° C. and at 35 C. in the incubator, in similar media, invariably resulted in identical growths. Cultures on boiled potatoes in test-tubes were prepared by inserting a piece of raw potato, cut with an apple-corer, in a sterile test-tube, in the bottom of which had been placed a short piece of glass tubing; together with 10 c.c. of sterilized distilled water, after which the plugged tubes were boiled for half an hour in the steam sterlizer, and on two subsequent days were again sterilized at a temperature of 100° C. for ten minutes. It might be added that, when properly prepared, these tubes may be kept for weeks, or even months, and are always ready for use.

Inoculations of the potatoes were made from the gelatin and agar-agar colonies; the tubes placed in the incubator at 35° C. after twenty-four hours showed the development along the track of the needle of a narrow transparent film, which acquired a yellow, honey-like appearance in the course of the next two days. This colony gradually underwent changes in color from reddish to a dark sepia, and was surrounded by a bluish-black zone, which after a month had become of a dark indigo-blue tint. The surface of the potato surrounding the colony had a distinctly bluish tinge.

Very characteristic growths were obtained by employing sweet potatoes (convolvulus batatas) as the culture-medium. These were prepared in the manner as described for ordinary potatoes.

This culture-medium, it may be stated, has also been found to be a very fertile soil for various species of microörganisms—the bacillus of anthrax, the bacillus megaterium, the bacillus of blue milk, the bacillus figurans, and the various pyogenic cocci, growing rapidly, and developing highly characteristic colonies.

Inoculations from plate-cultures that were placed in the incubator at 35° C., after twenty-four hours showed a prolific growth of honey-like colonies along the track of the needle, which in the course of a few days became dotted with minute greenish-black spots. This coloring rapidly overspread the whole infected area, gradually assuming a darker hue, which after a week resulted in nearly the whole surface of the potato becoming black.

Slides were prepared of nearly all the colonies, and the appearances in all were identical.

After a series of experiments, in which almost all the methods recommended for staining were tried, it was found that most satisfactory results were obtained by staining with Löffler's blue for twenty-four hours, rinsing with very dilute acetic acid (½ to 1 per cent.), washing thoroughly with destilled water, then with alcohol, clearing with xylol and mounting in xylol-balsam.

The bacilli were generally arranged singly, occasionally in pairs at right angles, or in V-shaped figures. In shape they resembled tubercle bacilli, being probably a trifle thicker but no longer than these as ordinarily seen in cover-glass preparations of tuberculous sputum.

On September 7th, some blood freshly obtained from the patient was examined. Microscopically bacilli were found as before, also a few cocci. As a matter of interest it may be mentioned that, although the blood was enclosed in a cell and examined immediately, an abnormally large number of crenated red blood-corpuscles was noted. Staining gave poor results. Plate-cultures made from the same specimen gave two kinds of colonies: some were identical with the colonies obtained from the serous fluid, while the others developed as small, round masses that gradually liquefied the gelatin surrounding them, and that on further investigation proved to be made up of the staphylococcus pyogenes aureus. Inoculation-experiments from the first-named colonies yielded results similar to those narrated.

On September 9th, a small nodular abscess on the neck was opened, and the stringy, whitish, purulent fluid was experimented with. Plate-cultures again yielded two varieties of colonies, which proved similar to those obtained from the blood. No account was taken of the number of colonies of each kind developed, but it is probable that a great many staphylococci were present, as the plates rapidly liquefied. We made no further experiments, as the evidence furnished justified us, in the present state of our knowledge concerning the etiology of acute glanders in man, to pronounce the case an undoubted one of this disease. The diagnosis based on the clinical history and bacteriological experiments was further corroborated by a statement made by a

brother of the patient a few days after the death of the latter that the patient had lately been in charge of sick horses, all of which had died. The fact that no cause for this fatal illness could be assigned is, of course, significant, as it is well known that farcy contracted by man from horses is a most virulent disease.

As the bacteriological investigation furnished no evidence of erysipelas or septicemia, which might have been suspected, these may be definitely excluded.

For permission to make this publication we are indebted to Dr. Adam Trau, in whose service at the German Hospital the case occurred.

The clinical history has been furnished by Dr. Ross, while the bacteriological experiments were carried on in the bacteriological laboratory of the hospital by Dr. Frese and Mr. Ross.

PROGNOSIS IN EPILEPSY.[1]

BY A. W. WILMARTH, M.D.,
ASSISTANT SUPERINTENDENT AT THE PENNSYLVANIA INSTITUTE FOR FEEBLE-MINDED CHILDREN, ELWYN, PA.

THE question that always meets the physician on assuming the treatment of a case of epilepsy is the probability of ultimate recovery. It is, of course, impossible to give a positive decision in any case until we have had the patient under observation for a time; but there are certain factors that will aid us in the matter and at the same time guide us in medical treatment.

The following observations are based on the study of 342 cases that have been under the writer's direct care and 437 cases that had recovered before coming under his observation, or in which the clinical history had been furnished by the parents or friends of the patient.

Single attacks of convulsions, coincident with dentition, acute illness, or injury, have been excluded as possibly not being of a truly epileptic character.

Perhaps the most important point in judging of the probability of ultimate recovery is the age at the time of the onset of the disease. When the first attack of convulsions occurred before the third year of life, in a little more than half the children attacked they ceased before the age of puberty. Selecting 566 cases, the histories of which seem reliable, 52½ per cent. have recovered, having no spasms up to the time the history was recorded. The prognosis grows progressively graver as age advances, and when the spasms persist or begin after puberty recoveries are extremely rare, though even at that age the convulsions occasionally do cease. In my records I find only six such cases. Persistence of the convulsions is usually indicative of structural changes in the brain-substance, and mental instability or decadence will, as a rule, accompany them. When convulsions begin after injury to the head, making their appearance after the immediate effects of the accident have passed away, they are usually of grave significance, indicating that organic changes have followed the traumatism; and, unless these changes can be promptly checked by tonics and hygienic measures, recovery is hopeless.

The relation of heredity to recovery is a perplexing one, from the reluctance of the relatives to acknowledge mental imperfection or nervous disease in their family or from their inability to recognize it. In estimating the following percentages, I have omitted all cases in which the history seemed indefinite, and also those in which there was habitual drunkenness in parents or grandparents, and have included only well-defined cases of mental disorder or organic brain-disease in the ancestry.

In 273 cases in which hereditary influence was established, a little over 42 per cent. persisted, while in nearly 58 per cent. the convulsions had ceased. Of cases in which no neurotic taint was discovered, 38 per cent. recovered and 62 per cent. persisted. This result we might expect, the former class inheriting more sluggish brains, less liable to respond to irritation by convulsive explosions; while the last-named group includes more cases of traumatic origin, those originating in brain-injury received during the initial stage of the eruptive fevers, and more of those beginning during the later years of childhood or the period of rapid development that occurs between twelve and fifteen years of age. These changes are often ushered in by a period of unusual cerebral activity and precocity that is the pride and delight of the parents and too often the doom of the child.

An important point, and one not often mentioned in text-books on epilepsy, is *periodicity* of spasms. By this I mean that they will recur at very regular intervals if the patient is made to adhere to a regular course of living and the natural sequence of the convulsive attacks is not interrupted by remedies. The following cases will illustrate my meaning:

CASE I.—H. D.; spasms occurred with almost unfailing regularity every four days; he finally died of convulsions that lasted several hours, with intervals of two and a half minutes, never varying over five seconds from the expected time until a little while before death, when the intervals lengthened. Post-mortem examination revealed sclerotic changes in the left motor region. (An illustration of this case may be seen on page 45 of Dr. Osler's *Cerebral Palsies of Children.*)

CASE II.—T. D.; spasms recurring with intervals of about fourteen days and at the rate of one a day for two or three days at a time; death from menin-

[1] Read before the Association of Medical Officers of American Institutions for Idiotic and Feeble-minded Persons.

gitis. There was sclerosis of the anterior half of the right hemisphere.

Case III.—M. C.; spasms so frequent as to make it difficult to follow this point, but at such times as they would become less frequent they would seem to follow the rule. Sclerosis of the entire right hemisphere was found at the autopsy.

Case IV.—L. R.; attacks of spasms lasting from two to four days occurred, with intervals of about fifteen days; death was due to meningo-cerebritis. Sclerosis of the right parietal lobe and implicating the occipital was found.

Case V.—T. L. F.; the seizures occurred at very regular intervals. There was general adhesion of the membranes to the cerebral cortex, evidently from a former attack of meningitis.

Case VI.—J. L. B., with structural disease of the brain, finally dying from bulbar paralysis, was another marked example; his spasms usually occurred every fourth day.

Case VII.—E. M.; the attacks took place at intervals of from six to seven days. There was sclerosis of both frontal and occipital lobes of a microcephalic brain.

The following cases illustrative of the periodicity of the epileptic seizures are at present under treatment:

Case VIII.—W. P.; spasms were reported June 15th, 21st, 27th, July 2d, 18th, 24th. (The gap of sixteen days between July 2d and 18th may have been filled in by a night-spasm not seen by the nurse.) Again he has spasms reported for August 1st, 11th, 21st, 31st, and September 10th, when the brain-irritation seemed less intense. In this boy rapid mental decadence and the development of right hemiplegia indicated a serious brain-lesion.

Case IX.—Similar to the foregoing, but less exact in the regularity of his attacks, is the case of T. W., in whom the spasms continued for many months with intervals of about two weeks. In his case mental failure was very rapid.

I have dwelt at considerable length upon the periodicity of the occurrence of the epileptic paroxysm, because it seems an important one in aiding us to decide whether the convulsive attacks in our patients are due to simple over-excitability of the convulsive centers, which manifests itself only when special irritative conditions may exist, or whether they are due to a definite cerebral lesion, which by its constant irritation gives rise to periodic explosions.

The intervals between the convulsive seizures can, of course, be modified by imprudence in diet, excitement of any kind, or by inhibitory remedies, such as the bromides, etc.

If the paroxysm is accompanied by mania, especially if transitory mania seem at times to replace the accustomed spasm, the prognosis is grave.

Such cases should not be confounded with those in which true convulsions appear to be replaced by short periods of excitement, which in rare cases do occur, perhaps to cease in their turn as recovery advances.

In regard to the effect of long-continued epilepsy on the intelligence of the patient, our opinion must be very guarded. A few convulsions in infancy do not appear to be always detrimental to proper mental growth. In exceptional cases they may continue for years without apparent impairment of the intellect. More often the violent disturbance of the circulation and consequent nutrition of the hemispheres, or local hemorrhages, may produce early symptoms of mental incapacity, or these may develop only after a considerable period. It is difficult to understand how the central nervous system can withstand the shock of frequent epileptic paroxysms, for any continued period, without serious impairment of its normal action, and our opinion as to the future mental condition of our patients must either be given with caution or be for a time withheld.

A HINT TO THE LITERARY MEN OF THE PROFESSION.

By CHARLES PERRY FISHER,
Librarian of the College of Physicians of Philadelphia.

I have been induced to write the following from the frequent loss, both of time and patience, that as a librarian I have seen occur to many literary men of the medical profession. I take the liberty to offer a few suggestions—rules, if you will—that would occasion no additional trouble, and, if adopted, would be of great assistance and a saving of labor to all. I refer to the inaccuracy and want of regularity in making and quoting references.

In the first place, if possible, all authors should verify any reference that they wish to quote. As is very well known, a great many writers do not take the trouble to do this. I have frequently had shown to me by the more careful authors, errors in references that they wish to quote, that have been used over and over again by numerous writers, running back for many years; in one case the original was over two hundred years old, and had been quoted perhaps fifty times, and yet it was quite evident that not one had cared to take the time to seek the original. Surely what an author thinks of sufficient value to incorporate in his work should be worth both the time and trouble to verify.

In the second place, I would call attention to the desirability, in making a reference from a book or monograph, of giving the name of the author, with his initials, place of publication, date, volume—if more than one—and page. For instance: "Bell, B., Syst. of Surgery, Edin. 1791, vol. iii, p. 16;" not, as is the custom of many writers, "Bell's Surgery, vol. iii, p. 16." When making a reference

to a journal, the writer should give an accurate copy of the title, place of publication—when not included in the title—date, volume, and page. The custom of using the editor's name in quoting a journal is very objectionable. For example:

"Hays's Journal" for "Amer. Journal of the Med. Sciences."

"Chapman's Journal" for "Phila. Journal of the Med. Sciences."

"Foster's Journal" for "Journal of Physiology, London."

"Magendie's Journal" for "Journal de Physiologie, Berlin."

"Langenbeck's Archiv" for "Archiv f. klin. Chirurgie, Leipzig."

"Sajous's Annual" for "Annual of the Univ. Med. Sciences, Phila."

An editor may have been so long connected with a journal, and be so well known by his writings or otherwise, that his friends may in a complimentary way associate his name with the title of the publication with which he is concerned; but such usage is certainly incorrect and misleading. How many of the younger men of to-day in France, Germany, or even in the United States, meeting with a reference to "Chapman's Journal," would know its title, or even that it was published in Philadelphia? In all the better catalogues a reference is given to the editor's name, of course; but it must be remembered that a large number of readers have not access to such catalogues.

Another form of quoting titles, even worse than the foregoing—for one will not often find a cross-reference of the kind in catalogues—is that of transposing or dropping a word from the title; as—

"Brooklyn Annals" for "Annals of Surgery, Brooklyn."

"N. Y. Record" for "Medical Record, N. Y."

"Zeits. für Chirurgie" for "Deutsche Zeits. f. Chirurgie."

Even the single word "Centralblatt" is sometimes used, the reader being left to discover the journal referred to (there are six or seven "Centralblatts") by the subject of the paper.

The foregoing suggestions with regard to journals are just as applicable to Reports, Proceedings, and Transactions. In fact, whenever a title is quoted, let it be an exact copy of the title-page, abbreviated if necessary.

In conclusion, I would repeat what I have said in the beginning: the adoption of these suggestions will cause little or no additional trouble to writers, and will save much time and labor to many readers. I have no doubt that a great many readers will say there is nothing new in what I have stated, and that authors know how to make references; this may all be true, but I know that the "workers" will agree with me, that, although they may have such knowledge, they too frequently fail to apply it.

ORIGINAL LECTURE.

MELANCHOLIA: ITS DIAGNOSIS AND TREATMENT AT HOME.

A Clinical Lecture
Delivered at the New York Polyclinic.

By W. B. PRITCHARD, M.D.,
LECTURER ON MENTAL AND NERVOUS DISEASES.

Gentlemen: The clinic of to-day illustrates the most common type of mental disease that in general practice you will be called upon to treat. The three patients before you are examples of the condition of mental disease known as melancholia. Each of the three represents a different variety of the affection, and yet, happily, the essential identity of the three cases is quite evident. You will recall the fact that in a recent lecture I gave you a classification of insanities, with a sub-group of melancholias, practically limited to three forms: Simple melancholia; melancholia with stupor, or, in its profound form, melancholia attonita; and finally, melancholia agitata. The disease being established, the condition is one that is ordinarily easily recognized. It must not be forgotten, however, that cases of general paresis and other forms of organic insanity may present an initial stage of symptomatic melancholia. As distinguished from mania, this is a condition of mental depression, or, as Bevan Lewis has expressed it, a mental state characterized by "a rise in subject-consciousness and a loss in object-consciousness." Cerebration and mental life are dominated, to a greater or less degree, by an exaggerated tendency to introspection, and a morbid exaltation of the *ego*. As in other forms of insanity, there may or may not be illusions, hallucinations, or delusions. There are emotional disturbances of the nature of depression, representing mental or psychical pain. There may be, and usually is, impaired will-power, and in all cases there is danger of the development of a morbid propensity to self-destruction. Illusions are relatively rare; hallucinations are less so and are frequently of the auditory variety. These patients "hear voices," for example. Delusions are exceedingly common in the agitated and the stuporous forms of melancholia, and are often found in the simpler cases. I have found visceral delusions especially common. A patient "has lost his stomach," "the liver is rotten," "the blood has dried up," "the body is dead," etc.; or the delusion may be purely psychic: a terrible calamity is about to befall a patient or some one of the household. The delusion may be one of suspicion: the patient's friends wish him out of the way; they are trying to poison him, or to get possession of his property. Or the patient may be utterly depressed, in the depths of abject despair, through some imagined act done in gross violation of the laws of God and man. Punishment is constantly impending in this world, and there is an inevitable hell in the next. Such patients are said to have "the delusion of the unpardonable sin," and such a delusion involves a degree of mental torture that not even hell can rival. It is small wonder that, if uncontrolled, such

patients, as a grateful release, put an end to their lives. Certain of these mental perversions give origin to other symptoms: A delusion of poisoned food will cause a patient to refuse to eat to the point of actual starvation. Fear of an impending calamity will cause loss of sleep, the patient fearing that death will overtake him before he wakes, or that the house will burn down, or the walls fall in. Insomnia, by the way, as has been pointed out by Dr. Landon Carter Gray, is a symptom of great value in these cases, especially in the simpler forms. He has also called attention to another symptom, very common and of much diagnostic importance in such cases, a post-cervical or occipital ache or pain. I have found these two symptoms, insomnia and a post-cervical ache, pain, or other discomfort, in fully 95 per cent. of all cases observed. In the stuporous form of the disease, especially melancholia attonita, the cerebral reflexes are so obtunded that it is difficult to get an intelligent appreciation of a question or even an answer at all. Such patients will often show the presence of this pain by attempts to rest the head, or by repeatedly clasping the hands back of the neck.

To sum up, you have as symptoms of melancholia, a state of more or less profound and unreasonable mental despondency, with emotional disturbance, impaired will-power, morbid propensity (suicidal tendencies), with or without hallucinations and delusions, and with an obstinate insomnia and a post-cervical ache or pain. There are other inconstant physical symptoms in body-wasting, a sallow, dry skin, coated tongue, obstinate constipation, in women amenorrhea, etc., but these are not diagnostic or of value except by association. A peculiar pulse-rate, running up to 110, 120, or 130, is quite common, however, and is worthy of special mention. It is especially noticeable in stuporous melancholia and in that agitated, agonized form in which is found the "delusion of precordial fear."

Let us see how our patients here fit into these symptom picture-frames. The history of the first patient is as follows:

Miss D., aged twenty-four years, native of Ireland and employed as a domestic, was seen by me at her sister's home in September last. I found her crying, and she did not want to see me, insisting that she was not sick and did not need a physician, but a priest, to whom she desired to make confession of something she had done that was terribly wrong. She said she was to be punished by the law for her misdeeds and that I was an agent of the judge, sent to secure evidence to be used against her at her approaching trial. She hoped, but did not believe, that the priest could give her absolution, so grievous had been her offence. She would like to die, she said, but for the fact that she would go straight to hell. There were other delusions, but these are sufficient. I could not establish the presence of hallucinations. The patient's manner was one of intense emotional agitation of a subdued character. She was sad-visaged and anxious, crying quietly most of the time, often walking up and down the room, wringing her hands. From the sister I learned that there was no ancestral insanity and that no known cause existed for her condition. The patient had always been of a retiring, shy disposition. For two or three weeks previously to my visit she had slept badly, had lost her appetite, and her general health had run down. However, nothing was noted as wrong with her mentally except much nervousness, until two or three days before my visit, when she had been found crying in her room at night, unable to sleep, and with the delusions mentioned. At no time had she complained of her head. Under treatment she has improved, until now, ten or twelve weeks later, she is quiet, as you see—rather unnaturally so. Her skin has cleared up, her constipation has been relieved, and she sleeps well, though still dependent on hypnotics. Her delusions have almost entirely disappeared during the past three weeks, and but for the fact that she shows a rather too intense desire to go to church and confession on every possible occasion, she might be pronounced entirely free from delusions. She is, at times, somewhat emotional, cries rather easily, and likes to be alone, showing a condition of mental hyperesthesia, so to speak. Her principal complaint, however, at this time, is of a constant *headache*, located in the *occipital* region. She is not by any means well yet, and even after recovery there will be danger of a relapse if she is not carefully watched. Here you have a history quite typically illustrative of what was, when I first saw it and for some time subsequently, a case of melancholia agitata, but which, as you see it to-day, presents the picture of a simple melancholia, affording an example of that to which I have called your attention before —*i. e.*, a transition in the symptom picture from one type to another. The treatment in this patient's case was carried out at home. The sister was carefully warned of the danger of suicide, and of the necessity for constant watchfulness. The fact that this patient has never made any attempt at self-destruction is no evidence that the warning was not required, but is rather proof of the good results of its observance. The insomnia was the most conspicuous feature demanding immediate attention and to overcome it sulfonal was used in doses of fifteen grains, in milk, at bedtime. It is a very reliable, pure hypnotic, but cannot be used with advantage in certain cases because of its effect upon the circulation, depressing the heart's action. I have twice seen cyanosis and partial heart-failure from its use in moderate doses. You can combine with it, as I did in this instance, sodium or potassium bromide, though the bromides must also be carefully watched lest they add to the depression. For the general condition, I gave opium in the form of an aqueous extract, in tablets of one-fourth grain each, at first three times daily and now twice. The use of this preparation was first suggested by Dr. Gray, as having almost specific properties in melancholia. I sometimes combine with it the extract of cannabis Indica (English), in doses of one-fourth to one-third of a grain. Cannabis Indica seems to prove especially beneficial in the hypochondriacal forms of simple melancholia, with visceral delusions (hypochondriacal melancholia of Savage and others). Extract of malt for the promotion of nutrition, elixir of calisaya as an appetizer, and extract of cascara sagrada as a laxative, constituted the remaining therapeutic measures. This patient will remain under treatment for three or four weeks longer and even then she will have made a comparatively prompt recovery, the duration of such cases being from eight or ten weeks to a year or longer.

This second patient comes to the clinic for the first time to-day. She tells me that she is a widow, that she is

thirty-seven years old, that she was married seventeen years ago, and that she has four children. There is no insanity or other hereditary affection in her family history. She is, as you see, of robust physique and the picture of physical health. She comes to us for relief, she says, from obstinate headache and great nervousness, assuming the form of a constant dread that something terrible is going to happen. Her head began to trouble her five years ago, at which time also her nervous system was badly out of order, as it also is at present. She was at that time nursing a six-weeks-old baby, and attributes her symptoms to a sudden suppression of milk. "Her milk went to her head." At that time she slept badly. All her symptoms, however, improved and gradually disappeared until some four months ago. About that time her husband left home, ostensibly to attend to a business transaction in a neighboring street, and a few days later his body was found in the bay; it was supposed that he committed suicide. The shock brought back all our patient's symptoms in a more aggravated form than ever before. She cannot now sleep more than three—rarely four—hours in the twenty-four, and she has terrifying dreams when she does sleep. She is always sad and almost constantly in tears, crying, as she expresses it, for little or nothing. Her head aches all the time. It is of pain in the *back of her head* and *upper part of the neck* that she complains. She is in constant dread of some terrible calamity, and is also afraid she will take her own life. When asked if she has ever attempted suicide, she answers, with a suggestiveness to which I call your attention, "Not yet." When spoken to about her husband's death, she shows a bitterness which is utterly unreasonable. She "will never forgive him for having taken his own life—he had no right to do it." He left her a good business and a $2000 life-insurance policy, which she had much trouble in collecting, but which she admits that she finally got; but she still insists that he has treated her and his children "with unpardonable injustice." She has no hallucinations that I can discover, and there are no other delusions than those of fear and of her husband's injustice. The case, gentlemen, is one of simple melancholia, with a relapse brought on by the shock of her husband's tragic death. Under treatment the patient should make a good recovery. The duration of treatment in this case may be two months, or it may be six. She will be given the aqueous extract of opium, gr. ¼, t. d. At bedtime she will be given either thirty grains of chloralamid, a most excellent hypnotic, or twenty grains of sulfonal. For the headaches, we shall use galvanism, the positive pole over the nape of the neck, the negative over the forehead. Both electrodes should be of good size. The dose of electricity will be from one and a half to three or four milliampères, for five minutes, three times a week. In some of these cases it affords astonishingly rapid and complete relief. Occasional doses of the bromides may be required, and precautions must be observed to prevent suicide, which, however, will show a tendency to diminish in a direct ratio with recovery of sleep. You will have opportunity to see the further progress of the case at a future clinic.

The third patient, this young man, some of you, perhaps, remember to have seen some three months ago. Those of you who do remember his former appearance before the class at that time are doubtless not a little surprised at his changed appearance to-day. His case is a most interesting one. His history, as written when I first saw him, is as follows: H. M., nineteen years of age, a barber, is the oldest of three children. The second child is a stutterer, the youngest is an epileptic. The father is, and has been for years, grossly alcoholic, and is of a vicious, quarrelsome temperament. The mother is subject to attacks of major hysteria. This patient was a frequent victim of his father's alcoholic wrath and was repeatedly driven violently from home into the streets. He formed bad habits and became addicted to excessive sexual debauches. He worked away from home, and his parents saw little of him for some time previous to his attack. Nothing of value as to the primary onset of his trouble can be determined. The parents first knew of it through a note from the patient, dated in jail, to which he had been committed for attempted suicide, a policeman having fished him out of the river, into which he had jumped from a ferry-boat. He was brought home by his parents, and was under other treatment for two weeks or more before I saw him, having in this time made two attempts at self-destruction, once by swallowing sulphur match-heads, and again by attempting to jump from the window. When brought to me his condition was one of purely automatic existence. His expression was that of fixed despair. He stood in the room until gently pushed into a chair, and refused to answer a question or speak a single word during the entire visit. For several days he had not spoken a word. His eyes would fill with tears occasionally as I talked with his mother about his condition. He acted like one stunned or shocked. His mother stated that he would not eat, that he would not bathe, or dress himself when undressed, and that he passed water only when it overflowed, the patient not showing any conscious knowledge of the act at all. He would lie awake all night, his eyes wide open and fixed upon the wall, at times crying silently. There was most obstinate constipation, the tongue was coated, the skin muddy and dry, the breath foul. Recognizing in his physical condition the basis for the term melancholia—Μέλας, "black," and Χολή, "bile,"—as used by the originators of the word, I put this patient on large doses (twenty drops) of dilute nitro-muriatic acid t. d., adding strychnine gr. $\frac{1}{45}$, to each dose. I gave him twenty grains of sulfonal at night, and put him on the aqueous extract of opium, gr. ¼, four times daily. He was fed mechanically at first, after which he began to eat a little voluntarily. Galvanism to the brain was used and also to the spine—the latter, I confess, somewhat empirically. The patient emerged from a melancholia attonita and, indeed, from a condition very much like katatonia (Kohlbaum, Spitzka—a form of melancholia with stupor, catalepsy, and a tendency to repeat again and again the same words or sentences, known as "verbigeration") into a case of melancholia with stupor and thence to recovery, which is, as you may see for yourselves, perfect. This patient had illusions, hallucinations, and delusions. He would falsely interpret centrally an external object that really existed. His illusions were optical and auditory: a shadow on the wall was "a man after him;" the sound of a pump in the cellar was interpreted as his death-knell;" later on, the sound made by moving his joints, the

"cracking" we all hear at times, especially in "loose-jointed" people, he interpreted as that of a "hinge" or a foreign body in his ankle. He heard voices in a medium of absolute silence, an auditory hallucination, a false *central conception* of something having no real existence externally. His illusions and hallucinations became fixed ideas—*i. e.*, delusions. These were particularly conspicuous of the viscera. His cerebral reflexes were so exceedingly dulled that I could not determine the presence or absence of occipital or post-cervical headaches. Later, as he got better, he complained of them, though not as being severe. This young man in spite of bad heredity—which, by the way, does not in such cases necessarily mean a bad prognosis—has made a most excellent recovery. He is bright and intelligent, and, after the lecture, you will find it of interest to get from him his recollections of his sensations and impressions while in his stuporous state.

Here then, gentlemen, you have three cases illustrating as many types of the same disease, melancholia, the last case being one of melancholia with stupor, or melancholia attonita, a more profound degree of the first. The points of special emphasis are, first, as to diagnosis and particularly as to the diagnostic value and constancy of a post-cervical or occipital ache, and insomnia in association with unreasonable mental depression, as evidence of the simpler forms of the disease or the primary stages of all forms. These three conditions being present, you should be on your guard against suicide, a source of danger in *all* cases not capable of exaggeration. The favorable prognosis under proper treatment to be given in the majority of cases of melancholia is also illustrated in our clinic to-day. A final point for emphasis is with regard to the value of the aqueous extract of opium as a quasi-specific, and as to cerebral galvanism, that not only often quickly relieves the headaches, but very greatly ameliorates the state of mental depression and dependency.

HOSPITAL NOTE.

RESULTS OF THE ANTIPYRETIC TREATMENT OF ENTERIC FEVER BY MEANS OF COLD WATER EXTERNALLY.

By E. C. ELLETT, M.D.,
RESIDENT PHYSICIAN IN ST. AGNES'S HOSPITAL, PHILADELPHIA.

[Service of John K. Mitchell, M.D.]

Since the antipyretic treatment of enteric fever by means of the cold bath was brought into prominence in Philadelphia by Dr. Wilson it has been pretty thoroughly tested in most of the hospitals in the city, and all seem to have agreed as to its many advantages. Dr. Wilson's well-known article (The Medical News, December 6, 1890) shows a large percentage in favor of this plan as pursued at the German Hospital compared with the methods of treatment then in vogue at the other institutions in the city. The method advocated by Dr. Wilson is the Brand treatment, or strict cold bathing. The plan pursued in the treatment of the cases here presented was rather what Dr. Wilson calls the "antipyretic treatment," with the addition of drugs to meet other symptoms. The results are very gratifying as having reduced the mortality in this institution to 18 per cent. less than it was for the portion of the present year from January 1st to August 1st.

The mortality of enteric fever in this hospital since it was opened in April, 1888, has been somewhat above the average. For the year 1889 the death-rate was 10.5 per cent.; for 1890 it was 26.6 per cent. From January 1, 1891, to August 1, 1891, it was 24.7 per cent. By comparing the results in the following cases with the preceding figures a better idea can be gained of what the cold-water treatment has done, than by a comparison with the statistics of other institutions. Hospital statistics regarding the disease under consideration are notoriously misleading, but by such comparison tolerably credible conclusions may be drawn. It should be remembered, however, that the number of patients treated is very small to deduce generalizations from.

The cases here presented were treated during Dr. John K. Mitchell's term of service, in part of which Dr. C. W. Burr was his substitute, and to them I owe thanks for permission to publish this report.

The total number treated was thirty-one, in the months of August, September, and October of this year. Of these we lost two, giving a mortality of 6.5 per cent., which contrasts favorably with the figures above quoted. The disease was of average severity, quite severe in several cases, and well marked in all. Eight of the patients suffered relapses, none of which proved fatal. Two cases of intestinal hemorrhage occurred, but both recovered. One had hemorrhages before admission, and this was one of the patients that died. One case was complicated with acute laryngitis, but this was promptly cured. In no case did bedsores appear, this being probably due to the cleanliness attendant on frequent bathing, the healthy action of the skin thereby promoted, and the rest afforded by the bath to parts ordinarily subjected to pressure. The maximum number of baths given to one patient was sixty-five, the minimum one. The patients were mostly young adults—nineteen males and twelve females. One boy of five and another of eight were among the number. The classical symptoms of the disease were well marked in all, except that constipation presented more frequently than diarrhea. No fixed rule was observed regarding the degree of pyrexia that should indicate the bath, but generally it was given when the thermometer registered 103° F., and for the last month 102.4° F. was usually the signal. The peculiarities of each case were always considered when determining this point, thus treating the person rather than the disease.

The method of applying the bath was as follows: A portable bathtub was filled with water at the temperature at which it came from the faucet, cooled with ice during the hottest days, and warmed as the weather grew cooler, to about 70° F. This tub was rolled into the ward beside the patient's bed, and without exertion on his part he was then lifted into the bath. A cloth wet with cold water was then applied to the head, and the bath continued until the temperature fell to about 100° F. The patient was then lifted on to a blanket and wrapped in it a few minutes, until dry, when he was changed back to bed-dress and sheets. Each bath was followed by a small dose of whiskey.

The average time occupied in thus reducing the tem-

perature was about twenty minutes. Ten minutes often sufficed, while in some instances it had to be prolonged to an hour or more. Especially was this true when the temperature was over 104° F. on going into the bath. The patients, as a rule, took kindly to the bath, and while rebelling at the first one or two, soon found that the subsequent relief was ample recompense for the temporary discomfort. Marked asthenia contra-indicated the bath, and existed in but two cases, both of which recovered. Only once did intestinal hemorrhage coexist with hyperpyrexia, and then the cold pack was substituted for the bath with gratifying results. In several cases, as before mentioned, the bath was resorted to but once, the temperature remaining within reasonable limits after that. It was in these cases that the most striking effects of the treatment were seen, an artificial crisis being induced. The patient put in the tub with high temperature, dry skin, brown dry tongue, flushed face, dull expression and muttering, slept after the bath, to awaken refreshed, with cool, moist skin, clear in expression and intellect, and proceeded on to prompt recovery.

Aside from the bath the treatment was liquid diet, oil of turpentine, gtt. x, t. d., in emulsion, and whiskey, half an ounce every three hours, increasing the latter as often as a compressible pulse and loss of the muscular element of the first heart-sound indicated stimulation. About a third of the cases received no turpentine. Quinine was given to some when defervescence began, and quinine and iron were largely used during convalescence.

The histories of the two cases that died are as follows:

CASE I.—H. W., female, twenty-five years of age, married, was admitted August 30, 1891. The family history and previous personal history were good. The following facts were obtained from her husband: She had not been well since the birth of her last child, three months previously. She complained more of general weakness than of any special symptoms. A week ago she was obliged to take to bed. Since then she has had fever, some vomiting, and diarrhea. She has had two hemorrhages from the bowels. Examination showed the patient to be in stupor, from which she could not be aroused to answer questions, though she could protrude the tongue, and she took medicine and nourishment. Her position was supine, with anxious expression, somewhat restless, face flushed, tongue dry and coated, with sordes on the teeth. The abdomen showed the eruption of enteric fever, gurgling in the right iliac fossa, and tenderness was inferred from the expression when pressure was made in the same region. Temperature 104° F. She was treated by the cold pack and sponging, with free stimulation. She died the third day after admission. No autopsy.

CASE II.—P. M., male, twenty-one years of age, admitted August 31, 1891. His family and previous personal history were negative. He began to feel badly about the middle of August, with weakness, headache, pain in the back and in the bones, etc. He kept at work until August 22d, when he was obliged to take to bed. He had been working on a dredge-boat, and was laid up in a sailors' boarding-house, without any attention until he came to the hospital. On admission he complained of weakness, pains in the body, legs, and head, and diarrhea. The tongue was dry, hard, and coated; sordes were on the teeth. On examining the abdomen the characteristic eruption was found to be present. There was neither tenderness nor gurgling elicited by pressure in the right iliac fossa. The abdomen was somewhat full and tympanitic; the temperature 100°; the area of splenic dulness considerably increased. He was treated by free stimulation with whiskey, and cold baths p. r. n. He became delirious on September 2d, and remained so until he died, September 7th. Before death the temperature rose to 106.8° in the axilla. An autopsy showed extensive ulceration of the lower portion of the ileum. The mucous membrane for two inches from the ileo-cecal valve was destroyed over almost the entire circumference of the intestine, clearly showing the transverse muscular fibers. The cecum showed many ulcers. The mesenteric glands and spleen were much enlarged.

These two cases were, of course, exceedingly unfavorable for any treatment, and are samples of the class of cases that make hospital statistics so misleading as regards the efficacy of any plan of treatment on the mortality of this disease.

CLINICAL MEMORANDA.

UNIQUE CASE OF INTUSSUSCEPTION.

BY MORRIS B. MILLER, M.D.,
RESIDENT PHYSICIAN PENNSYLVANIA HOSPITAL.

THE following case of obstruction of the bowels, due to intussusception of the ileum, in which probably the whole of the invaginated portion of the bowel was discharged a week before death, presents some points of pathological interest and renders the case, on account of the rarity of similar ones, worthy of being placed on record.

The strenuous reparative efforts of nature to overcome intussusception, and its effects after the parts have become so firmly attached as to prevent reduction, were shown in this case to a remarkable degree, and the fact that death did not occur for over a month after the involution took place shows that restoration of the lumen of the bowel and consequent recovery is not impossible in these cases where the integrity of the peritoneal cavity is in any way preserved.

Mrs. E. M., aged thirty-six years, a Russian by birth, was brought to the Pennylvania Hospital, June 1, 1891, in a condition practically of collapse, due, as it soon appeared, to some intestinal obstruction.

The following history was obtained. She was a married woman and had borne several children. the youngest being twenty-two months old; her health had always been good up to five months before admission, when she commenced to have much pain at her menstrual periods, with a scanty flow. Three weeks before her admission to the hospital she began to be constipated—not very severely at first, but during the second week her bowels were only moved once despite frequent and varied doses of purgatives. Three days before admission she commenced to have numerous bowel movements, accompanied with sharp, cutting pains in the left side of the abdomen. These pains continued

throughout the next day, and toward night she developed considerable tenesmus, with small bloody stools. On the day before admission, with the idea that it might give her relief, she took a large quantity of the juice of sauer-kraut, which increased her pain, and shortly afterward her abdomen began to assume the proportions which it had when she came under observation. During this time she had had no vomiting, but when she was brought in she had some retching, with eructations of gas.

On examination she was found to be very pale, with hands and feet cold, and with a blue, pinched, anxious expression. Her tongue was slightly coated; her pulse rapid, 128 per minute, weak, and slightly irregular; temperature 99°; respirations 48. Her decubitus was dorsal with knees drawn up, but this position was not absolute. Examination of the heart and lungs was negative. The abdomen was very much distended in a pyriform shape—with rather more distention on the left side—tympanitic throughout, and exceedingly tender, especially about the umbilicus. Vaginal examination showed the uterus to be very hard and immobile, and the pelvic floor bridged over by a hard exudate, which was especially marked toward the left side. The examination was very painful. Rectal examination revealed nothing.

The treatment was stimulation, with small doses of anodyne for the pain, calomel in small doses, and turpentine stupes locally. The means employed to relieve the obstruction and the tympany were the usual ones of high enemata—soap and water, and oil—and the rectal tube, but all were without avail. Her diet was restricted to peptonized milk given often and in small quantities.

The next day her condition was better, the tympany was not so marked, her pulse was of better character, and generally she seemed improved. However, at this time there commenced a symptom which continued with a greater or less severity throughout her entire illness, viz., diarrhea, which was evidently one of irritation, the stools being numerous—as many as twenty-four in the day—small, very offensive, and of a thin pea-soup character both in color and consistency.

From the 2d to the 5th she seemed to slowly improve; her temperature remained between 99° and 100°, her pulse about 96 and of good volume, her respirations approximated 30 per minute, and pain became a much less prominent symptom. However, the abdominal distention remained and the diarrhea was still pronounced.

On the 6th it was noted that to the left and below the horizontal line of the umbilicus there was a region irregular in shape, extending downward to Poupart's ligament, over which there was more tenderness, more resistance to the hand, and having a rather lower percussion note than the rest of the abdomen.

Stimulation was reduced at this time and the calomel stopped. Efforts were made to check the diarrhea, but it continued despite all treatment, and in fact it seemed that such medication acted unfavorably on her general condition. An exploratory laparotomy was suggested, but the advice of the surgeons called in was that medical treatment could probably be continued further with greater advantage.

On the 12th it was noted that the woman's condition was distinctly worse; she had commenced to have night-sweats, she had wasted considerably, and the involved area had become more apparent and had greater resistance. Stimulation was increased and anodynes became again necessary on account of increased pain, but by the 14th she had once again improved, and it seemed as though recovery was possible.

The evening of the 15th she had much more pain coincident with an elevation of temperature of 102°, and late at night she had a large, loose movement, which contained a stringy, shreddy piece of the small intestine *twenty-seven* inches in length. This piece was an intact cylinder at one end, but much torn at the other. On holding it to the light the muscular striæ together with some of the intestinal glands could be well seen, but the mucous surface was macerated off in the greater part. The peritoneal surface showed slight flakes of lymph, but there were no evidences of peritoneal adhesions having been formed.

The next morning the woman was much weaker and seemed exhausted, but her temperature had dropped to 98.8°. The belly was much more tympanitic than before, and occasional hiccough was present.

On the 17th she passed two more pieces of bowel of the same character—one was two inches in length, the other four—and again on the 18th, a single piece of twenty-one inches, in which distinct Peyerian patches could be seen.

From this time until the 20th, when she was removed from the hospital, against our advice, by her densely ignorant husband, she grew slowly weaker, but in other respects her symptoms were unchanged.

Her death occurred five days after her discharge, and fortunately an autopsy was secured. The notes that follow render the report complete.

Post-mortem, made twenty-four hours after death: Rigor mortis firm. Upon opening the abdomen the omentum was found adherent by comparatively recent lymph to the abdominal wall to the left of the median line and below the horizontal line of the umbilicus. Upon separating this with the finger, a large cavity was opened, which evidently had recently contained pus or feces. This pocket was formed by layers of the omentum and adhesions between the coils of the intestine, and was at least two inches by seven in size. Further examination found the small intestine—evidently the ileum—considerably congested and adherent to the neighboring coils. While endeavoring to discover the position that had been the seat of the invagination, feces began to flow into the abdominal cavity and masked the appearance of the parts so that the exact location could not be determined. The cecum and the appendix were normal, as also were the ileo-cecal valve and the adjacent portion of the ileum. The colon, ascending and descending, was normal. The uterus was bound down by old inflammatory lymph and could be separated only with difficulty. After considerable research the left ovary was found; it was of normal size, but on section contained pus. The Fallopian tubes were so matted down that they could not be examined.

The examination was conducted under great difficulties, on Front Street, near Bainbridge, in a miserable

hovel, without proper light, and with the woman's husband and other relatives watching that nothing was removed.

The microscopical examination of the pieces of the bowel which were passed before death showed conclusively that they were portions of the ileum. These pieces, which have been preserved in the museum of the hospital, measured in the aggregate fifty-four inches.

I am much indebted to Dr. Morris J. Lewis, who was at the time the visiting physician to the hospital, for his kind permission to publish this case.

DEATH FROM PNEUMOTHORAX FOLLOWING ABORTION.

BY ALLEN A. JONES, M.D.,
INSTRUCTOR IN PRACTICE, MEDICAL DEPARTMENT, UNIVERSITY OF BUFFALO.

ON November 7th, a woman was brought to the General Hospital suffering from intense dyspnea, with pallor, slight cyanosis, rapid, feeble pulse, subnormal temperature, and giving evidence in every way of shock. It was hard to obtain a satisfactory history, and only in a vague way we ascertained that a few days previously the patient had had an abortion, followed by chills and fever. It was said that she had been treated for intermittent fever; however that may be, her condition was certainly alarming on her admission to the hospital, and Dr. Stockton at once set about ascertaining the cause of her extreme dyspnea. A physical examination soon confirmed the existence of pneumothorax of the right side. A moderate-sized needle was plunged into the pleural cavity, and by the aid of the Allen pump a steady volume of air was withdrawn. But in spite of our best efforts the patient received no relief, and died a few hours later.

The autopsy, by Dr. Bergtold, showed a large, well-developed woman, about thirty-three years of age, with a heavy layer of adipose. Rigor mortis was present.

The right pleural cavity was full of air, and there was a very foul odor upon opening the right chest. Two openings were found at the anterior edge of the middle lobe of the right lung, at which point rupture of a small abscess, near the surface of the lung, had occurred, rendering patent two small air-tubes, over which a portion of exudate acted as a valve, preventing any return of air from the pleural cavity. The right pleural surface was covered with inflammatory lymph; there was a small quantity of pus in the meshes of lymph about the seat of the rupture. There was collapse of the right lung, with complete atelectasis of the upper lobe. There were no large abscesses. There were evidences of recent acute bronchitis.

In the left lung small hemorrhages were scattered all over its surface, with slight edema of the lower lobe, and a small infarct in the posterior portion of the lower lobe.

There were about four ounces of fluid in the pericardial sac. The heart weighed about eleven ounces. The left ventricle was empty, and the right ventricle contained a recent clot. The aortic and pulmonary valves were competent; the right and left hearts and the aorta were normal.

There was localized pigmentation of the peritoneum. The spleen was large and soft, and, on removal, parts of its surface tore away. The gall-bladder contained about one hundred gall-stones, varying from the size of a pin-head to that of a hickory-nut. The right kidney was pale, the capsule adherent, with scars, the cortex narrow. The evidence seemed to establish an acute nephritis, superimposed upon a chronic nephritis. The left kidney was large, the capsule slightly adherent, its surface pale and injected, the cortex narrow.

The serous surfaces of the ovaries showed injection and pigmentation; the organs were of normal size. The uterus was slightly enlarged, its surface injected. The endometrium was acutely inflamed, and lined by decomposing pus and detritus. In the right uterine vein a large septic thrombus extended from the uterus the whole length of the vein, and entered the ascending vena cava for about an inch. The stomach, intestines, and pancreas seemed normal.

This case is especially interesting as one of those rare instances of sudden death from an affection of an organ most remote from the seat of primary disease. There can be no doubt that a fragment of the septic thrombus found in the uterine vein and vena cava was carried to the right heart and thence to the lung, where it set up localized suppuration, which, in turn, resulted in the destruction of the termini of the two small bronchi found patulous, so that the air was thus suddenly thrown into the pleural cavity.

Perhaps more might have been accomplished by freely opening the pleural cavity, as in Estlander's operation, but I doubt the probability of any measure saving this patient's life, when we consider the profound septicemia from which she evidently suffered.

This case preaches an eloquent sermon to those at all inclined to be negligent in the proper after-treatment of abortion.

CHLOROFORM-POISONING.

BY W. A. DEWOLF SMITH, M.D.,
SURGEON TO THE BRITISH COLUMBIA PENITENTIARY; VICE-PRESIDENT B. C. MEDICAL COUNCIL, NEW WESTMINSTER, B. C.

ON the night of the 4th of March, 1891, I was by telephone requested to see a woman at the police-station, the officer on duty informing me that the woman had poisoned herself. When I arrived at the station I found the woman in a semi-conscious condition, sitting on a bench, being supported in that position by the officer who had brought her in. I was informed that she was supposed to have taken a dose of chloroform, with suicidal intent. I at once caused her head to be lowered, and loosened her corsets and other garments. She was at this time quite unconscious, the breathing slow but shallow, the pulse rapid and weak. The conjunctivæ were insensitive. Having no stomach-pump at hand, I injected hypodermatically one-third grain of pilocarpine, which in a few minutes produced emesis. There was a very strong odor of chloroform in the vomit. After the emetic had acted the pulse slowly began to improve, and as she could not swallow I at intervals injected hypodermatically six or eight drams of brandy. She was now laid on a bed, and as she apparently felt chilly, was well wrapped up in blankets and let alone. In about two hours she began to recover consciousness, and was soon able to tell that she had had an ounce-bottle of chloroform, and desiring

to end her life had taken some of it, she did not know how much. She had been able to walk about the streets for an hour, when she was found by the officer, leaning against a building, her knees hardly able to support her. With his assistance, however, she walked to the station, and there fell into the unconscious state.

Judging by reports in the medical journals that I have at my command, poisoning by chloroform is comparatively rare, and death from it seems rarer still. In some cases respiration has had to be kept up, or stimulated, by electricity or other means, but in this case the breathing, although shallow for a time, never showed any tendency to stop.

A remarkable point in this case is the length of time the woman was able to walk about after the chloroform was taken. In another case[1] it is recorded: "T. D., aged sixty, took about half an ounce of chloroform, mistaking it for spiritus chloroformi. I was called about ten minutes after, and found him nearly insensible; five or six minutes later he was perfectiy unconscious." In another case,[2] a man is said to have walked 250 yards, and was soon after found unconscious in his bedroom, after having swallowed two ounces of the drug. In this case the quantity swallowed did not exceed one ounce, but the distance walked by the woman was nearly a mile, besides which she went over part of the distance two or three times. It is difficult to determine the fatal dose of chloroform, for one dram is said to have caused death in a child,[3] and Dr. Saunders[4] mentions a case in a man that was fatal in thirty-six hours after one ounce, and one which was fatal in forty-eight hours after six ounces

ARTIFICIAL EYES INSERTED WITHIN A WEEK AFTER ENUCLEATION.

By GEORGE M. GOULD, M.D.,
OPHTHALMOLOGIST TO THE PHILADELPHIA HOSPITAL, PHILADELPHIA.

It is commonly advised that artificial eyes should not be prescribed until three or more months after enucleation have passed. This period is a sore one for most patients, the appearance of the empty socket or the "black blinder" being equally unpleasant both to the patient and to his friends. Relying on the well-known tolerance of the orbit for foreign bodies, I have in three instances advised the insertion of the shell within a week—once on the fifth day and twice on the sixth. In another case it was put in on the tenth day. All wore the artificial eyes from the first, not only with no inconvenience or bad results, but with entire satisfaction and comfort.

MEDICAL PROGRESS.

Pancreatic Diabetes.—Dominicis (*Münchener medicin. Wochenschr.*, October 13 and 20, 1891) has conducted a series of experimental investigations, the results of which lead him to conclude that, as a result of destructive disease of the pancreas, there develops a grave form of diabetes, of which the characteristic feature is not glycosuria, but a progressively fatal marasmus. This form of diabetes is considered a constitutional derangement of nutrition, attended with increased tissue-metamorphosis, and dependent upon the removal of influences inherent in the pancreatic secretion.

Conjoined Administration of Potassic Iodide and Insufflation of Calomel.—Kanasugi (*Berlin. klin. Wochen.*, September 7, 1891) has reported a case of syphilitic laryngitis in which the conjoined internal administration of potassic iodide and insufflation of calomel were followed by acute laryngitis, with edema, dyspnea, hoarseness, and pain. It has been known that calomel, dusted on the conjunctiva in course of the administration of potassic iodide, occasions conjunctivitis. It is conceived that the action is dependent upon the local formation of an iodide of mercury.

The Sequelæ of Influenza.—In the course of a series of lectures at Gresham College, Thompson (*British Medical Journal*, October 24, 1891) called attention to the pulmonary and nervous sequelæ of influenza. The asthenic, suppurative pneumonia and pleurisy—types that ordinarily appeared only in broken-down constitutions—afforded strong evidence of the depressing influence of the disease. It was maintained that there was a sharp contrast between the nervous sequelæ of influenza and those of diphtheria. In diphtheria the paralysis was motor; in influenza it was essentially sensory. The gastric complications that, with the pulmonary, were so fatal in the latter part of the epidemic, were referred to the nervous system, as were also the cardiac complications. The especial frequency of symptoms referable to the lungs, stomach, and heart suggested the action of a toxic agent upon the pneumogastric nerve.

A Case of Extensive Syphilitic Endarteritis.—Kauders (*Wiener klin. Wochenschr.*, No. 42, 1891) has reported the case of a man, thirty-five years old, with a specific history of six years' standing, who presented symptoms of mental confusion, vertigo, and failing memory; especially was the memory of recent events impaired. The right upper and the left lower extremity were enfeebled and slightly wasted. For six months there had been no radial pulse at the right wrist, the vessel being replaced by a firm cord. Speech was slow, hesitant, and slightly ataxic. The tendon-reflexes were exaggerated; sensibility was unimpaired. Seven weeks after first coming under observation, the man suddenly lost consciousness, with the restoration of which it was observed that right hemiplegia and aphasia existed. At this time it was noticed that the terminal phalanx of the great toe of the left foot was mortifying. Sixteen weeks subsequently the man died, the urine having been diminished, together with the presence of a considerable quantity of albumin and of granular and blood casts. At the autopsy an area of softening was found in the left temporal lobe, while the artery of the fossa of Sylvius was occupied by a loose, yellowish-brown thrombus. The wall of the vessel was thickened and vitreous, but the lumen of the vessel was not narrowed. The remaining vessels of the base and convexity were normal. The basal ganglia of the left hemisphere were softened. The heart was small and atrophic; its valves were normal. The intima of the ascending aorta was greatly thickened,

[3] Guy and Ferrier.
[4] Loc. cit.

uneven, not fatty, calcareous, or ulcerated. The orifices of the coronary valves were narrowed. The upper half of the spleen was broken down into a cavity containing fluid and necrotic tissue; the lumen of the arterial branch passing to this portion of the organ was closed by enormous thickening of the intima of the vessel. The intima of the splenic artery and of its other branches was thickened, but in slighter degree. The right kidney was one-fifth of its normal size; its surface was irregular and nodular, and marked by atrophic cicatrices; the renal artery and its branches were greatly thickened and their lumen narrowed. The left kidney was of normal size, but deformed by cicatricial contraction. The right femoral vein was occluded by a yellow, softened thrombus, which extended into the inferior cava. The left femoral artery and the brachial, with their branches, were diminished in capacity by thickening of their intima; as were also the right femoral and the left brachial, though in minor degree.

Diplakusis.—Before the Berlin Society for Internal Medicine, TREITEL (*Berliner klinische Wochenschr.*, October 19, 1891,) described as diplakusis a condition in which sounds are heard differently with both ears. Two forms are recognized: diplakusis binauralis and diplakusis echotica. In the former, music, or tones, or voices are heard more distinctly with one ear than with the healthy ear, or apparently louder than they really are. The condition is commonly associated with disease of the ear. In diplakusis echotica, however, speech also is heard double. The difference between the true sound and the false sound is not always alike. It may vary in the same person, even in the course of a day. The derangement is not organic, but functional. In one of two cases the condition developed from use of the telephone; in the other, after rupture of the tympanic membrane. It is thought to be dependent upon fatigue consequent upon abnormal stimulation of the auditory muscular apparatus.

Meriatchenje is the name applied by TOKARSKI to a condition observed in Siberia, in which individuals without other abnormality involuntarily perform senseless, sometimes criminal acts, spontaneously or in obedience to commands from others, or repeat words or actions that they hear or see. In one case, the condition had existed for thirty years in a woman seventy years old, following a fall from a horse, with loss of consciousness. In a second case, in a woman thirty years old, the condition had existed for two years, since the death of her husband. In four other cases there was an irresistible tendency to imitation, induced by anger or fright. The disease affects principally the natives of eastern Siberia, but Russian immigrants do not escape. It has occasionally been observed to be epidemic. The maladies described by voyagers to Java, Singapore, and North America as lata, sapitlakar, and the jumping disease, appear to be identical with meriatchenje, the identity of which with tic convulsif, however, is disputed.—*Revue de l'Hypnotism* (*La Méd. Mod.*, No. 35, 1891).

Successful Laparotomy for Traumatic Rupture of the Small Intestine.—At a meeting of the Royal Society of Physicians of Vienna, JAHODA (*Wiener medizin. Presse*, No, 43, 1891) reported two cases of traumatic rupture of the small intestine successfully treated by laparotomy. In both a blow upon the abdomen was followed by symptoms of internal incarceration. In one case laparotomy was performed eighty hours, in the other twenty-five hours after the accident. In both, a brownish fluid was found in the abdominal cavity; the small intestines were agglutinated by fibrino-purulent adhesions; and in a loop of bowel, at the free surface opposite the attachment of the mesentery, there was a perforation. Lembert sutures were introduced, the deposits gently removed, the abdominal cavity irrigated with a one-tenth per cent. solution of salicylic acid, graduated suture of the abdominal walls performed, and drainage provided for. In one case, union took place by first intention; in the other the lower portion of the wound failed to unite primarily.

Dermoid Cyst of the Bladder.—REHM (*Wiener medizin. Presse*, No. 43, 1891) has reported the case of a man who presented the symptoms of imperfect evacuation of the contents of the bladder. The urine was normal; the left lobe of the prostate was apparently enlarged. The patient was instructed in the employment of the catheter and was sent home. A few weeks subsequently he again presented himself with the symptoms of a putrid cystitis. Examination disclosed the existence of a false passage in the membranous urethra, and thrombosis of the left femoral vein. The enlarged lobe of the prostate was sensitive. Irrigation of the bladder and drainage by perineal section failed to relieve the man's condition, so that as a last resort the bladder was entered from above the pubes. The mucous membrane was lined by phosphatic deposits. Posteriorly to the entrance of the left ureter there was a flat tumor, of the form of a cock's comb, that bled readily. Close behind the tumor there was a diverticulum occupied by a cyst that contained decomposing atheromatous matter and hairs. The cyst was removed and the man ultimately recovered.

A Sign of Pleural Effusion.—At a recent meeting of the Medical Society of Lyons, COIRAT (*Wiener medizin. Presse*, No. 41, 1891, p. 1557) reported a case of hydrothorax in a child, of which the only evidence was an absence of the breath-sounds. By compression of the base of the thorax, egophony was elicited, disappearing with the removal of the pressure. In cases of slight pleural effusion in children, except when the fluid is encapsulated, the level at which egophony is heard may be altered by moderate compression of the chest.

Celluloid Plates in the Closure of Trephine Openings.—At a recent meeting of the Royal Society of Physicians of Vienna, FILLENBAUM (*Wiener medizin. Presse*, No. 43, 1891) presented a soldier in whom a celluloid plate was used to close the opening made in trephining on account of a complicated fracture of the skull. The wound healed without suppuration. The case was the fifth of its kind thus treated.

BILLROTH added that he had at his clinic satisfactorily treated a considerable number of cases in the manner indicated. The hopes from this method in cases of traumatic epilepsy were, however, not realized.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment. When necessary to elucidate the text, illustrations will be provided without cost to the author.

Address the Editor: GEO. M. GOULD, M.D.,
1004 WALNUT STREET,
PHILADELPHIA.

Subscription Price, Including Postage in North America.

PER ANNUM, IN ADVANCE . . . . . $4.00.
SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, DECEMBER 12, 1891.

A GREAT MEDICAL DISCOVERY IGNORED.

THERE are few medical truths that have been discovered fraught with more possible and incalculable good to humanity than one that is ignored by the great body of the medical profession.

There are explanations and sufficient reasons for this anomalous fact. Among them may be noted these:

1. The discovery has come about slowly and silently. It has been made by no one man and has come with no flourish of international congressional trumpeters. So softly and slowly has it crept into scientific medicine that its own advocates are but half aware of it, and do not yet realize its almost unparalleled value.

2. It is a therapeutic measure that depends for its exercise upon an exactness of knowledge of delicate mysterious physiological and psychological functions that few possess, and upon a subtle discrimination and judgment with which, by character or education, few are endowed.

3. It has the misfortune to depend for its promulgation and practical application upon the specialist, and almost upon the specialist of a specialty—and this in a profession and in an epoch in which it is fashionable to sneer at specialism, and at the specialist who dares plead for the truth he knows—and that, at first at least, only he can know.

4. The tradition and habit and ambition of the ophthalmic specialist is to treat diseases—inflammations—or to perform operations upon the eye. The truth is that refraction-work has come into tremendous importance, and must make up nine-tenths of the routine practice of the future ophthalmologist.

Is it an exaggeration to say that the chief complaints of fully one-half of the patients that apply to the family physician, are of headache and digestional affections? Is it another exaggeration to say that fully one-half fail to get permanent relief?

Is it again an exaggeration to say that from these causes a large proportion of women have hopelessly resigned themselves to a lifetime of wretchedness?

The oculist daily has patients who have spent (to them) fortunes paying physicians and druggists; who have taken everything and done everything for ten, twenty, or thirty years, to get relief from wretchedness beyond description. No physician ever said "eyes" to them. Yet a pair of glasses relieving the compound hyperopic, perhaps unsymmetrical, astigmatism and anisometropia, give relief as if by magic.

If these things are true to anything like the extent contended for, the general standard of health is being distinctly lowered and the average vitality of the race lessened by a cause that so generally and so profoundly affects its mothers for evil. Headache—deranged function of the organ that controls vital function—and digestional abnormality—nutrition being the very source of vital power—have an evil significance impossible of over-valuation.

For twenty years the ophthalmologists have been tirelessly preaching that eye-strain due to refraction errors is the chief causational factor in the production of headache. This is a truth, and yet the truth is ignored the world over. In Europe it is hardly suspected, commonly scouted, and, so far as therapeutic application is concerned, hardly dreamed of. It is only in the United States, and even here only in one or two cities, that the truth has a comparatively adequate application. To the great majority of those of the country who are suffering from ametropically-caused disease, no word has come as to the origin of their trouble.

But this, as regards headache alone, is only half of the truth. Wherever there is headache there is nutritional disturbance. In rare cases there may be a digestional reflex neurosis without headache

and due to ocular irritation. Usually the headache precedes or accompanies. Hence it is that the full power of eye-strain to work disaster will never be realized until there is a general recognition on the part of the profession that anorexia, dyspepsia, and constipation are very, very frequently due directly to eye-strain. It is perfectly useless to sneer at hobby-riding. The sneer will not alter the fact or relieve the patient. It were better and more scientific to test the theory with a mind free of prejudice. One little proof is ready to hand: let the sneerer put on a pair of spectacles such as every oculist applies every day to correct ametropia. At most it will take but a few hours for the artificial ametropia thus produced to bring on headache, and not only anorexia, but probably vomiting. There is one other test, easily applied: paralyze the accommodation for a week or two in a young patient suffering from *possible* reflex ocular neuroses. The frequent relief will be a striking lesson in differential diagnostication.

Sick-headache, from which thousands in every community are sufferers, is usually if not always due to eye-strain, and, unless of life-long duration, is quickly curable by a pair of proper spectacles.

Anemia is, perhaps, most frequently due to the ocular irritation of uncorrected ametropia, followed by nutritional disturbance. Many cases of hysteria have the same etiology.

But possibly the worst result of eye-strain is the generally impaired nutrition, the "nervousness," the neurasthenia, the reduced vitality that so far lessens resisting power as to make the system incapable of withstanding infectious disease or exceptional strain of any type. Eye-strain is a common and great soil-exhauster for the in-rooting of a prolific crop of the weeds of general disease.

The "nervous" origin of disease is a fact becoming more recognized every day. If diabetes and albuminuria, as contended, may be of nervous origin, then diabetes, etc., may possibly be due to ametropia. Functional heart trouble, temporary anesthesia, and paralyses, localized pain, etc., may be caused by a deranged reflex from a morbid peripheral stimulus, such as that of the eye. Functional disease is the forerunner almost always of organic disease—the two are stages or phases of the same fact. Desire and physiological habit produce organs. Unhygienic habit and abnormal function wreck organs.

"But we cure headache, sick-headache, giddiness, anemia, and abnormalism of digestion by drugs alone, and every day." Willingly granted! because these affections are often, and perhaps generally, due to other than ocular causes. And more than this, powerful tonics may sometimes relieve, even when the neurosis is of ocular origin. It is an undeniable fact that some cures may be effected without touching the final and veritable causes of the disease. In stopping the one result of a reflex ocular neurosis by powerful drug-action, the reflex may be shunted elsewhere, or more probably the evil effect of forcing ametropic eyes to continue their work without correcting lenses will be to produce the local ocular evils of blunted retinal sensibility (amblyopia), ametropic choroido-retinitis, imbalance of the muscles (heterophoria), conjunctivitis, cataract, etc.

The cause of so much eye-trouble in modern life? A perfectly evident one: The eye in the animal world and in the human organism up to the present century was developed in response to definite need, that of the clearest possible distant vision. Civilization, demanding close and continued near vision, with its printing and writing and schools and commercialism, its indoor and urban life—all this is a thing of the past few dozen years. An organ produced by millions of years of reaction and habit cannot, without harm and injury, be forced in a hundred to a different usage. The tremendous importance of the eye to the organism makes Nature, with her subtle, wonderful wisdom, turn the irritational eye-strain reflex to brain or nutritive system—anywhere but to the all-important eye!—and hence it is that the eye does not feel pain, but other organs do. Inhibited reflexes produce general hyperesthesia, vertigo, and headache; switched reflexes produce neuralgia, anorexia, car-sickness, etc.

There is one other manner in which civilization may act upon the eye: the intense labor to which it puts the eye brings ocular irritation and congestion, with varying tension, that undoubtedly produce or help to produce corneal asymmetry or astigmatism, the great agent of eye-strain. The necessity for accurate vision, the slavish continuance of long ocular labor, spurs the over-sensitive ciliary muscle and nerve-centers to extraordinary exertion and, each aiding other, the vicious cycle is complete. The hyperesthetic sensibilities, the headaches, night-terrors, and anorexia of pale, early-forced, book-fed school children, are the inevitable product of far-sighted astigmatism and short-sighted ambition. The brain is forced to unwonted tasks with imperfect ocular means. A discriminating

physiologist sees that the eye is an organ fearfully overworked, bound up most intimately with every mental and physical act, most indescribably delicate in adjustment and function, and responding to a stimulus millions and millions of times more swift and more infinitesimally small than that of any other sense-mechanism of the body.

Psychologically, character and calling in life have doubtless often been changed and determined by ocular irritation. It is a truism that the disposition is entirely changed by it. The mind is almost the sole product of the function of vision, all thinking being in pictures, the very letters of the alphabet being conventionalized pictures. American morbid restlessness and hyperesthesia may to some extent be due to ocular irritation.

The practical lesson of it all is (so subtle are these beginnings and causes of evil) that every child, well or not well, should have its eyes examined to see if possible or unsuspected abnormity of the refraction exists. Especially is the possibility of an ocular origin to be suspected in all cases of mal-assimilation not clearly traceable to other causes, in all cases of headache, neuralgia, chorea, nightmare, insomnia, etc.

With this proviso and condition: That the ophthalmologist have been thoroughly trained in the very modern science and art of refraction, that a mydriatic be used, and that the refractive error be patiently and accurately worked out, not with the ophthalmoscope, but with the test-lenses, and worked out to a quarter or even to an eighth of a diopter, and that a painstaking optician fit and adjust accurately-made lenses. It is also necessary that spectacles be readjusted monthly so that they shall be kept with mathematical precision in their proper position before the eye.

CAUTION AS TO TURKISH BATHS.

A few weeks ago a young man died in convulsions in the hot-room of a Turkish bathing establishment in New York city, and last week another sudden death occurred just as the bather came from the plunge-bath. It therefore becomes a pertinent question if this form of bath may be attended with dangers, and should be surrounded with safeguards. It may be that in these cases the deaths were only indirectly or not at all due to the baths, but it cannot be denied that there is usually too injudicious and indiscriminate use of these baths on the part of the public and too much carelessness on the part of the attendants. As the business is commonly carried on, any person, well or ill, may take a bath, and may stay in the hot-rooms as long as he pleases. Very often the attendants are entirely oblivious of the bather's condition, or as to the length of his stay in the superheated apartment, because they have quite enough to do to care for each bather as he presents himself. Each bather is supposed to govern his actions according to his own private judgment. There can be little doubt that in certain forms of cardiac, arterial, and cerebral disease the bather should act only upon the advice of his physician, and there can also be little doubt that every bathing establishment should see that supervision and guidance are exercised over the bathers. The pulse-rate is immensely quickened in the hot air, and a too protracted stay has probably in many cases proved injurious.

The Turkish and Russian baths are largely supported by those prone to an excess of adipose tissue, in the belief that the bath serves to check or to lessen fleshiness. But without rigid attention to other factors, and without intelligent medical advice, the bath will have no such influence. The jockies that stay in the bath continuously for days, thereby reducing their weight five or six pounds a day, are quite as careful as regards diet, and they very speedily regain their former weight when "the races" have been run.

These baths are excellent therapeutic and hygienic agents, but their use or avoidance should be guided by professional advice, and with more discrimination than is usual; whilst on the part of attendants there should be a more watchful and intelligent supervision and guidance exercised over the bathers.

CARPETS AND INFECTION.

In the wonderful progress in the science and practice of hygiene that has come about during the last ten years, it seems strange that so little attention has been directed to carpets—an evil of which the effects can only be serious and extensive.

Not many years ago it was the pride of hospital-managers to adorn their wards with pictures, curtains, carpets, and every device of ornament now condemned; but the teachings of bacteriology so speedily made it clear how and to what extent danger lurks in beauty of this kind, that hospital-ornamentation is now a thing of the past. What is true of hospitals is certainly true, though to less extent, of the home. We know that every nook

and corner not readily reached in the daily or frequent dustings is a nidus for the lodgment, growth, and development of disease-germs, and perfect sanitation would require the reduction of these *ad minimum*.

Of all such depositories, none can be more productive of harm than carpets. Here is an excellent bed for the breeding of germs, and in the case of fluids, as, *e. g.*, expectoration, for their subsequent drying and dissemination as dust. The very warmth that commends the use of carpets is a potent factor in the preservation and multiplication of the bacterium.

This is but one aspect of the question, though a serious one. Carpets are answerable for yet other evils. Originally devised, no doubt, as much for warmth as for ornamentation, they have come to take the place of that solidity of structure that alone can secure healthful warmth. The flimsy, poorly-joined floors and doors of modern dwelling-houses make carpets a necessity for barest comfort, and have been made endurable only because of these defects. This is the serious aspect of the question in point of remedy. An uncarpeted floor means draughts, cold, and every circumstance of discomfort; and until houses are better built, no matter what elaboration of painting, staining, or polishing is bestowed upon the floors, their imperfections of structure would still make rugs or carpets a necessity.

We are not aware of any statistics to prove the unhealthfulness of carpeting, nor is it plain in what way reliable data could be obtained; yet we are none the less convinced that carpets exert an evil influence, especially in the propagation of our dreadest scourge, tuberculosis. That the sputum of phthisical persons may be dried, preserved, and disseminated in the dust of the room is a proposition that in the present state of our knowledge needs only to be stated to be believed. How often this has happened—indeed, is happening every day—and how often such infections pass for cases of family tendency and the like can only be surmised, but there can be little doubt that theory and fact are in close accord.

What can be done to remove this evil? Little, we confess; nothing without scientific agitation of the matter. Perhaps a radical cure is not to be expected, but a compromise may be effected. The necessities of our domestic architecture, the warmth insured, and the quiet that carpets secure, will effectually prevent any attempt at removal; but the same objects may be obtained from small rugs, which can be frequently dusted and at somewhat longer intervals taken to the cleaners for thorough steaming. Large carpets fastened to the floor, and to a less extent large rugs, not easily taken up for dusting, should be condemned.

A general spread of knowledge concerning the growth and diffusion of microörganisms will do much to secure the needed reform, but until public attention and fear are aroused nothing can be done.

CORRESPONDENCE.

"SENDING INVALIDS AWAY FROM HOME."

To the Editor of THE MEDICAL NEWS,

SIR: After reading Dr. Rogers's communication on "Sending Invalids Away from Home," in THE NEWS, I feel it my duty to indorse his views, and to add a word or two myself. The study of climatology and the selection of sanitaria are of great importance to the physician; but, unfortunately, they usually receive but little attention from the practitioner. How often is the advanced invalid sent far away from home, and from all that is dear to him, to be surrounded by strange sights and faces, in a strange land, whither he has been sent by a physician who had not taken the trouble to look sufficiently into the matter to qualify himself to decide the important question as to which particular climate or locality was most suitable for his patient's case.

In a paper that I read before the Philadelphia County Medical Society (February 24, 1886) there appears the following paragraph, which is so apropos that I quote it here: "How often have I met cases of advanced phthisis away from all the comforts of home and its surroundings, dying in a strange land, sustained only by hope and the fact that they were carrying out the physician's order. I wish that my words could only be made sufficiently impressive to picture to you as the subject comes up before me the many sad cases I have witnessed. It is easy for the doctor, who possibly knows that all hope is ended, and a fatal termination not very far distant, to say to his patient, Go to Algiers, go to Egypt, Australia, or Southern California. The poor unfortunate patient is at once inspired with hope; his weakened frame is sustained by the nervous energy which is brought by determination. The long journey before him is no obstacle; its discomforts are discounted, and yet he scarcely reaches his destination before nature gives way. The journey to a foreign land requires a degree of strength that is often surprising even to a man in good health. The wear and tear, the vicissitudes of temperature, the character of the cooking, the damp sheets and hard beds, are much more wearing than most of us imagine. Our Consul-General to Egypt some years ago told me that much of the business of the consulate was the caring for the baggage of the consumptives who had been sent from home in the last stages of the disease, to run down more rapidly, and

possibly die within two or three weeks of their arrival." One of the most shocking sights to the invalid travelling south is to run across the boxes with the death-certificates upon them, waiting for the northern trains. Although I have the greatest possible faith in change of air and residence in a suitable climate for those in the early stages of disease, or when a predisposition exists, or during convalescence, I am strongly opposed to the method at present adopted of recommending places in a general way, regardless of their suitability and other matters as important as the climate itself. A physician should know thoroughly the place to which he sends his patient. He should be as familiar with it as with the drugs he orders in his prescription.

Patients should be sent away in the early stages of their malady. They should remain away long enough to eradicate all traces of the disease that caused them to seek an equable climate, and, if their home is in the Middle, Eastern, or New England States, they should not return until summer has begun.

A three years' residence in Southern California has convinced me that patients must come early in their disease and remain long, otherwise their trip will prove futile, if not fatal. WILLIAM A. EDWARDS, M. D.

SAN DIEGO, CALIFORNIA.

A RATIONAL MEDICAL NOMENCLATURE.

To the Editor of THE MEDICAL NEWS,

SIR: In an editorial in THE MEDICAL NEWS of October 24, 1891, you refer to the importance of employing names descriptive of objects indicated, discountenancing the use of proper names. This evidently is the correct view to take. The sooner we change the course of this evil tendency the better. If the present mode of naming diseases, instruments, operations, and drugs be continued, medical literature will become a collection of meaningless terms, unintelligible even to the most scientific reader.

In the present advanced stage of medical science, it appears to me that our nomenclature should be technical; grave errors are frequently committed by misunderstanding terms, which could be avoided by adopting a universal technical nomenclature.

The use of proper names confuses the mind, encumbers the memory, and deforms the beauty of medical literature. Proper names should be used only from a descriptive or historic standpoint.

A recent number of one of our leading medical journals contained an article on "Supra-pubic Cystotomy," which forcibly illustrates the subject in question. It was said that "a soft catherer is inserted, and the bladder filled with eight ounces of warm *Thiersch's solution*, which is allowed to flow out through the catheter. . . . If the bladder is deeply sunk in the pelvis, the *Barnes dilator* may be inserted per rectum, filled with four to five ounces of warm water. . . . The most satisfactory instrument for removing tumors of the bladder is the *Spencer Wells* ovarian sac *clamp*. . . . The *Paquelin cautery* point may now be introduced and the base of the neoplasm seared over. . . . Temporary drainage is satisfactorily secured by the *Trendelenburg T-tube*. . . . Occasionally a small fistula may persist, which will require either to be packed with iodoformized gauze or scraped out with a *Volkmann's spoon* to insure its closure."

One may affirm, without fear of being accused of exaggeration, that the value of the article from which this extract is taken is greatly impaired by the use of proper names. H. F. SLIFER, M.D.

NORTH WALES, PA.

"PULMONARY TUBERCULOSIS AND MALARIAL FEVER."

To the Editor of THE MEDICAL NEWS,

SIR: It may be a question in the minds of some medical men whether or not pulmonary tuberculosis is ever diagnosticated malarial fever by physicians within the pale of the profession. It is my impression that the mistake is quite frequently made.

While attending the International Medical Congress at Berlin, a patient in the last stage of pulmonary tuberculosis, who had been under my care, fell into the hands of a physician who diagnosticated the case as one of marial fever, stating to the friends of the patient that he was "no death-angel," and that he would soon have the patient restored to health. Before the patient passed out of my hands there were large cavities in the apices of both lungs, and the objective symptoms were as pronounced as those described by Charles Dickens in the case of Smike: "There were times, and often too, when the sunken eye was too bright, the hollow cheek too flushed, the breath too thick and heavy in its course, the frame too feeble and exhausted, to escape regard and notice."

Notwithstanding the subjective and objective symptoms, and the fatal termination of the case, the physician believes or affects to believe that his diagnosis was correct, although "a little off" in prognosis.

Your editorial on this subject in THE MEDICAL NEWS of the 14th of November elicits the statement made above. J. F. JENKINS, M.D.

TECUMSEH, MICH., November 18, 1891.

SHOULD PHYSICIANS DISPENSE THEIR OWN MEDICINES?

To the Editor of THE MEDICAL NEWS,

SIR: Your article, "Physicians Should Dispense Their Own Medicines," will no doubt excite some discussion among physicians, and especially among pharmacists. The conscientious pharmacist cannot deny that there is a great deal in favor of this plan, although if carried out it would take the bread and butter from under his nose. At the present time every druggist must admit that cutting in prices is the increasing evil; that selling proprietary medicines at cost, and even below cost, is *indirectly* working harm to the physician as well as to his patients. Has it ever occurred to the physician that, in order to pay the large running expenses of a pharmacy in a great city, a big profit must come in somewhere? If it is not made on proprietary articles in combination with drug-trade and prescription-trade, then it must be made on the latter entirely. This intense cutting has caused unscrupulous druggists to lower their prescription rates to such an extent that in order to make any profit at all an inferior grade of drugs must be used, or an inferior class of prescription-clerks employed, and con-

sequently the life of the patient and the doctor's reputation are placed in jeopardy. It is my candid opinion that the physician whose practice is among the poorer class of people will run less risk to his reputation and put his patients in less danger by dispensing his own medicines, knowing that they are obtained from reliable laboratories; at the same time he will be striking a blow against hospital and dispensary evils and all irregular practice. Respectfully,

HENRY F. C. MÜLLER, M.D.

BROOKLYN, N. Y., November 29, 1891.

IDIOSYNCRASY.

To the Editor of THE MEDICAL NEWS,

SIR: An editorial in THE MEDICAL NEWS of November 14th impels me to record a striking instance of idiosyncrasy of which I am myself the victim. Early in my professional career, more than thirty years ago, I learned that the presence of the minutest quantity of ipecacuanha in the atmosphere was sufficient almost instantaneously to induce violent sneezing, with an attack of severe coryza, in conjunction with which asthmatic paroxysms occurred. Unwilling to surrender the use of ipecacuanha, I substituted a tincture for the powder. If in dispensing I soiled my hands with a drop or two of the tincture which I failed immediately to remove by washing, decided irritation was set up in those parts with which the soiled fingers came in contact. On each of the only occasions that I remember having taken ipecacuanha internally I suffered with excessive nausea, violent vomiting and retching, accompanied by a sense of burning pain and colic in the abdomen. In each instance I found speedy relief from the ingestion of castor oil. Yours truly,

JAMES MITCHELL, M.D.

MADISON, BOONE COUNTY, W. VA.

THE LENGTHENING OF TENDONS, ETC.

To the Editor of THE MEDICAL NEWS,

SIR: In your issue of November 28th you speak of the fact that a year ago, in ignorance of Dr. Rhoads's proposal for lengthening contracted tendons by splitting them, I published a paper describing the same operation, which was proposed to me by Dr. S. Weir Mitchell. I beg to call attention to the fact that in the *Lancet* of July 18, 1891, p. 109, Mr. Wm. Anderson, in his lectures on "Contractions of the Fingers and Toes," describes and figures precisely the same method, and he carried out the plan by operation on a young girl of seventeen, on October 18, 1889. It will be observed that while the idea seems probably to have been original with Dr. Rhoads, Mr. Anderson, and Dr. Mitchell, the first publication is certainly to be credited to Mr. Anderson. Yours, very truly,

W. W. KEEN.

NEWS ITEMS.

Dr. E. von Esmarch, son of the distinguished surgeon of Kiel, has been appointed Professor of Hygiene at Königsberg, succeeding Fränkel, who has been called to Marburg.

A new Russian Pharmacopœia is about to be published.

Gusserow recently celebrated the twenty-fifth anniversary of his accession to the chair of Gynecology at Berlin.

M. Pasteur has secured an annual subsidy from the French Government to enable poor persons living in France at a long distance from his institute to reach it in the event of their requiring his treatment.

Bamberger Fund.—The widow of the late Professor Bamberger has given a sum of eight thousand five hundred dollars, the interest of which is to be devoted for the benefit of poor, deserving students in the University of Vienna, irrespective of nationality or creed.

A Prize for African Investigations.—The King of Belgium has offered a prize of five thousand dollars, to be awarded in the year 1897, for the best presentation, from a sanitary point of view, of the meteorologic, hydrologic, and geologic conditions of equatorial Africa, together with the hygienic principles and rules to be observed in determining the mode of life, the character of nutrition, the form of occupation, the variety of clothing, and the kind of habitation. The essay must also include a consideration of the symptomatology, the etiology, and the pathology of the diseases peculiar to the country, together with the prophylactic and therapeutic measures to be adopted. Principles are to be formulated for the selection and employment of medicaments and for the establishment of hospitals and sanatoria. The investigations and the conclusions are to bear upon the conditions of life for Europeans in various parts of the Congo region. The competition is open to the world. The essays must be in the hands of the Minister of the Interior and of Public Education in Brussels by January 1, 1897.

The Adulteration of Drugs.—The Committee on Adulteration of the New York State Pharmaceutical Association recently made some investigations regarding the strength and purity of certain drugs extensively used in ordinary practice. Out of seventy-six samples of dilute acetic acid purchased in various towns between Poughkeepsie and Saratoga, only nineteen samples could be called good. The strength, which should have been 6.12 per cent., was found to vary from 0.8 to 29.8 per cent. Of forty-six specimens of Hoffmann's anodyne only five were good. Thirty prescriptions calling for stronger ether produced all sorts of make-believes; one druggist even sent a mixture of chloroform and alcohol. Only three out of fifteen samples of potassium iodide were respectable. This is heartrending. If we cannot have good iodide we might as well give up practising medicine. We think, Mr. Druggist, we shall have to come to a better understanding with you about these little matters, or else we shall have to dispense our own remedies, which custom you do not seem to approve.—*The Physician and Surgeon*, November, 1891.

VOL. LIX. SATURDAY, DECEMBER 19, 1891. NO. 25.

ORIGINAL ARTICLES.

OPERATIVE TREATMENT OF THE DEFORMITIES RESULTING FROM INFANTILE SPINAL AND CEREBRAL SPASTIC PARALYSES.

BY DEFOREST WILLARD, M.D., PH.D.,

CLINICAL PROFESSOR OF ORTHOPEDIC SURGERY, UNIVERSITY OF PENNSYLVANIA, AND SURGEON TO THE PRESBYTERIAN HOSPITAL, PHILADELPHIA.

INFANTILE spinal paralysis and cerebral spastic palsy are diseases entirely different in their pathological conditions, their symptoms, causes, and prognosis. The one is due to an anterior poliomyelitis, with changes in the anterior columns of the cord; the other to a destructive lesion of the cerebral motor-cells; but the late results demanding operation that will be considered in this article possess certain similar deformities in common, so that the two conditions may surgically be considered together. Of course, in the one case we have atrophy, loss of reflexes, paralysis of certain groups of muscles, etc., while in the other we have rigidity, paralysis with muscular spasm, irregular and uncertain contractions, but little real and sometimes no apparent wasting of the limbs, and the electrical reactions are not lost. The reflexes are also exaggerated in the cerebral type.

The permanent results obtained by operation are much better in infantile paralysis, for the reason that the disease that has occasioned the deformity, although permanent in its effects, may be said to be definitive, and without that tendency to relapse that is seen in cerebral palsy; yet even in the latter class of cases a certain degree of benefit is attainable.

In an article read before the Tenth International Congress at Berlin in 1890, I showed the results that could be obtained from surgical procedures in a large majority of cases of infantile paralyses even when they were helpless and apparently hopelessly deformed. The minor distortions were not considered, nor is it my purpose here to call attention to any but the almost desperate class of cripples in whom locomotion has become almost impossible, and who spend their lives upon the floor or upon a bed, and who are usually looked upon by physicians as beyond surgical relief. I have operated upon a large number of these cases, and am more and more convinced that those wholly beyond help are exceedingly few in number. While they cannot be made perfect and strong, yet by operation the power of locomotion can be greatly increased, and aided by the use of canes, crutches, wheeled apparatus, etc., strength of limb will be secured, greatly to the benefit of the physical, mental, and moral condition of the patient. As only the stronger muscles are divided, muscular equilibrium is assisted. The muscles operated upon are improved, and when some ability to walk is gained, increase of power by exercise is soon apparent. Let anyone who thinks that locomotion does not improve these limbs, look at the legs of a ten-year old boy with untreated club-foot, and at another similar case in which operation has been done early during this period of years, thus securing normal locomotion.

In spastic cases, of course, the improvement to be expected is far less. The disease is more centrally located, and the mental power of these individuals is decidedly defective. The improvement will be in proportion to the brain-power already existing.[1]

These children are brought to the orthopedic surgeon by parents expecting that skill can supply what Nature has denied them. I have sometimes had as many as a dozen new cases brought to my office in a single week, many of them hopeless idiots, but whose deluded parents thought them bright, intelligent children. This delusion being such a happy one, it is often unkind to attempt to explain to parents the full degree of the idiocy. While an injured brain-cell can never be replaced by a good one, yet I am fully convinced that great physical, mental, and moral benefit is to be derived from placing these individuals in the upright position upon some form of locomotive apparatus. I am very careful, however, as regards the prognosis.

Mechanical measures as preventives of deformity are exceedingly important, but for purposes of rectification they cannot take the place of surgical procedures. I consider it barbarous to attempt to rectify the deformities in this class of cases by the long and painful process of pressure, when, during a few minutes of anesthesia, surgery is capable of producing the results desired.

[1] I have been much surprised at the number of these spastic children, as in former years my experience had been largely among infantile spinal cases. I note, however, that Townsend and Zacks have found that they stand in the proportion of 39 per cent. spastic to 61 per cent. infantile. N. Y Med. Journ., May 21, 1891; Trans. Med. Soc. State of New York, 1890.

After operation, the limb is in nowise inferior in strength and development to the one afforded by mechanical measures, while the serious loss of time and money and the pain incurred in the latter slow method certainly demand consideration. No physician has a right to take money from patients by a slow, painful, and expensive method, when it is so entirely unnecessary.

When infantile cases are neglected and proper preventive apparatus has not been used, deformity follows from: 1, Degeneration of muscles; 2, atrophy; 3, contractures; 4, deficient and retarded bone-growth; 5, distortion of skeleton produced by efforts at locomotion.

The deformities of contraction are usually in the direction of flexion. Generally speaking, surgical procedures should consist in the division of all the contracted tissues, whether tendons, muscles, or fascia. The great cause of failure is in the too limited division—not from extensive section. In the majority of cases *the tenotome* is sufficient for this work. Open incision is advisable when there is great risk of injury to the bloodvessels or nerves.

In hip-contractures a tenotome with a long shank, introduced in front of the anterior spinous process, is capable of safely severing the origin of the tensor vaginæ femoris, the sartorius, the long head of the rectus, and all of the contracted fasciæ. Strong pressure will usually complete the extension of the limb and rupture the remaining fascial adhesions, provided the patient is placed upon his face and the pelvis is properly fixed.

In cases in which the psoas or iliacus has become shortened, subcutaneous incision becomes too dangerous and open incision should be performed.[1]

For all operative procedures the rule should be to bring the limb into such a position that in locomotion it will be mechanically able to support the weight of the body. In hip-contractures in which at the time of the operation this cannot be entirely obtained, it may subsequently be gained by the application of pulley-and-weight extension in the horizontal position. This extension should be continuous, and it will usually result in benefit not only to the hip, but to the accompanying lordosis. The scoliotic spinal distortions so often found in these cases are the most troublesome element in cure.

Flexion of the knee may be relieved by tenotomy of the semi-membranosus, semi-tendinosus, and biceps. In old cases the contraction of the fascia is often very great, and when it extends to the mid-popliteal region, open incision should be performed. In a recent case, even after open incision, it was impossible to elongate the popliteal nerve, which was so displaced from thickening of its sheath that in a subcutaneous incision it would have been mistaken for a tendon.

The use of extreme force in straightening the knee after deformity should be avoided, because it is liable to produce posterior displacement of the head of the tibia. Unfortunately, this is frequently acquired from long continuance of the deformity, and, as described later, more radical measures for its relief may be necessary.

Deformities at the ankle and foot are very common in infantile paralysis, which has a special tendency to implicate the muscles of the lower leg. The deviation is in the direction either of flexion, extension, inversion, or eversion. In talipes equino-varus (the most common form of deformity), the section of the tendo Achillis only is seldom sufficient. The foot should be brought into the best mechanical position; this means, that in walking the foot should be brought squarely upon its sole, and that extension beyond a right angle shall be easily performed, without undue tension upon the tendon. Section of the tibialis anticus, tibialis posticus, and plantar fascia, and, in fact, of all contracted tissues should be thorough. It is better to bring the foot straight at the time of operation than to half do the work, and then torture the patient by subsequent attempts at mechanical rectification. As the internal plantar artery is a small vessel, its division is of no consequence. All the tissues should be divided, even the lateral and plantar ligaments, if necessary. Powerful force applied over a hard sand-bag as a firm fulcrum is often necessary to secure complete rectification. On the inner side of the foot, subcutaneous division heals more quickly and leaves less deformity than open incision, but the division of all the tissues, save the skin, is nearly the same in either case.

In valgus cases the mistake is often made of supposing that only the peroneals are contracted. This is owing to the fact that the anterior part of the foot can easily be brought into such position that flexion can apparently be made decidedly beyond a right angle. The error arises from the fact that undue motion is obtained at the medio-tarsal joint, which, with the sinking of the scaphoid bone, gives the appearance of full normal flexion. A skilled examination of these cases will show that the articular facet of the calcaneus does not by any means assume its normal relation with the tibia and fibula. That which apparently was full flexion of the foot, is in reality not so at all, since the tendo Achillis is entirely too short to permit of the proper relation. The inferior calcaneo-scaphoid ligament is elongated, the result being a distortion of this articulation, a painful condition of flat-foot and a tender scaphoid that renders locomotion extremely difficult and painful. This mal-position of the os calcis, from the contracture of

[1] Had I performed myotomy subcutaneously in a recent case I would most certainly have divided the anterior crural, which lay externally to its normal position.

the calf-muscles, is very common and is often overlooked. This was markedly illustrated in a case recently under my care. The anterior part of the foot could apparently be brought far beyond the normal angle of flexion, and yet the os calcis remained decidedly in the position of extension and required fully half an inch of material in the tendo Achilis to permit a proper position to be attained. When the tendo Achillis is thus contracted, the strain in walking brought upon the calcaneo-scaphoid articulation is, as stated, very great, and its results harmful. For easy walking, flexion of the foot should be possible for from fifteen to twenty degrees beyond a right angle.

Section of the tendo Achillis, as well as of the peroneals, is, therefore, an important matter in the treatment of those cases; nor should the forcible reduction and subsequent retention of the misplaced scaphoid by gypsum be omitted. Continued retention of this misplaced bone should be secured by the use of a support placed beneath the plantar arch, which will assist in holding the bone in position, while at the same time the position of the bones of the foot should be altered by raising the inner side of the sole of the shoe so that the individual walks as upon the side of a hill. Care should be taken in the primary dressing to bring the calcaneum into its proper position.

For the primary dressings after any or all sections I prefer plaster-of-Paris. It sets rapidly, secures absolute rest, and favors healing. If swelling occurs, the cast may be slightly opened, or windowed, or if necessary removed.

In talipes calcaneus an open incision over the tendo Achillis, the removal of a section, and the suturing of the two cut ends with sterilized catgut will be helpful.

Under antiseptic conditions the subcutaneous operation is a safe one. I have performed it hundreds of times, and have never had a case of suppuration. If a surgeon operates upon a dirty foot with septic instruments he must expect poor results. Very few attendants will properly cleanse the epithelium from a deformed foot.

Open incision, with splitting and suturing the tendon, has been recommended on the ground that by the subcutaneous method we do not secure the exact amount of material required. I certainly have never experienced this difficulty, and, except in calcaneus, I see no occasion for the employment of the open method. If the foot is fixed in the proper position, Nature will supply the exact amount of material required, and the resultant tendon will be just the one necessitated by the case. I have had two and three inches inserted in a tendon and never had weakness as a result. I would expect to have such an accident if after the operation I followed the British plan of dressing the foot in the deformed position and then attempted later to rectify the deformity. Nature is perfectly capable of throwing out the one hundred parts required to bridge this gap, and will undoubtedly do so when called upon. When dressed in the deformed position possibly fifty parts are deposited which are necessarily incapable, when elongated, of filling the gap. A hundred parts could just as easily have been secured.

The question of age is of no special importance except as regards bone-distortion. Prompt healing of the tendons may be expected if careful antisepsis has been employed and subsequent rest enforced.

Resection of the knee is sometimes necessary when the displacement of bone is very great and when the distortion of the head of the condyle or of the head of the tibia is very marked. It is also sometimes desirable in a frail limb, when apparatus cannot be afforded and when a stiff knee will be of more service; also when there is a bad condition of genu-varum, valgum, or recurvatum.

In old cases resection of the astragalus or of other tibial bones is occasionally necessary, but, as a rule, thorough division of the contracted tissue and extreme force will rectify this condition.

Although sometimes justifiable, it is but rarely that amputation or osteotomy will be necessary.

Mechanical appliances. Rest should be maintained until all danger from inflammation is past. After two weeks crutches may be used and mechanical appliances employed. No rules can be given for the making of the apparatus. It must be so adjusted that it will keep the limb in the best position for walking and as accurately as possible in the normal position. Feeble muscles must be assisted by elastic or spring force, and, as necessary, a stop-joint or a locked joint employed. Every muscle should as early as possible be compelled to do its fullest possible work. In many cases with which we have to deal it is impossible to expect voluntary locomotion at first. Patients must be assisted by wheeled crutches or by crutches or canes in addition to apparatus. These appliances are as necessary to these cases as is an artificial limb to a man whose leg has been amputated. Electricity, massage, gymnastics, etc., should never be omitted.

Simple tenotomy of all the contracted flexor tendons is usually required. Myotomy of the adductors is also quite frequently necessary. The necessary operative procedures have already been described.

I present a few illustrative cases:

Case I.—J. C., seventeen years of age; infantile paralysis. Thighs flexed permanently. Has not walked for two years. Right foot equino-valgus; left, equinus. Pelvis, greatly tilted. Extreme lordosis; excessive lateral curvature of the spine with

marked rotation, protrusion posteriorly of left thorax. Arms, strong. The condition is shown in Fig. 1.

Tenotomy of the tensor vaginæ femoris, of the semi-membranosus and the semi-tendinosus on both sides; also of the tendo Achillis on both sides and of the peroneals on the right. Forcible extension and retention in plaster-of-Paris. Apparatus applied in six weeks. Legs still very helpless. Must walk on crutches for some time. Great difficulty in applying the apparatus on account of the lateral and backward tilting of the pelvis, which can never be cured, although extension and counter-extension while in bed has greatly helped the condition.

FIG. 1.

CASE II.—W. W., fourteen years of age; infantile paralysis in childhood. Has never walked since. Legs absolutely helpless. Flail legs from hip. No voluntary action in foot or toes. Excessive lordosis from tilting of the pelvis, which was raised on the right side three inches above the left. Excessive lateral curvature with rotation of the vertebræ and prominence of the left thorax posteriorly. Arms also extensively atrophied and very helpless. Flexion at thigh to a right angle; at knee nearly the same. Right foot, equino-varus; left, valgus. The whole body greatly emaciated and from insufficient food illy nourished.

The child was so feeble that after tenotomy on one side had been performed, it was necessary to wait several weeks before the other side could be operated upon.

Tenotomy of the tensor vaginæ femoris, the sartorius, and long head of the rectus, the hamstring tendons, and the tendo Achillis on both sides. The knees and feet were brought straight, but the thighs could not be put in normal position; nor could the pelvis be brought into its proper relation to the spinal column, because the latter was so greatly distorted. Long extension and counter-extension, however, added to the benefit obtained at the time of operation, but even after an apparatus with rigid joints was applied from the thorax to the feet, the arms were incapable of supporting the patient upon crutches. A wheel-crutch (see Fig. 2) was therefore constructed in order to support the weight of the body until locomotion could assist in giving some power to the legs. With this he was able to progress very well. A leather jacket encircled the body. Six months later the increase in the size of the legs was much marked, and the boy could knock them straight from the hip.

FIG. 2.

CASE III.—L. C., fourteen years of age; infantile paralysis in infancy; has never walked since except with apparatus with rigid joints. Flexion of both knees; hips and ankles are in good position; lateral curvature of the spine, with left rotation. Section of the hamstring tendons. Apparatus constructed; leather jacket; movable joints in apparatus, with elastic strings to assist all weakened muscles. With such assistance, after three months he was able to walk a mile. He was kept in plaster-of-Paris dressing for four weeks.

CASE IV.—J. M., eleven years of age; absolutely helpless from infancy; has never walked. Great flexion of hips and knees; feet but slightly distorted, as they have never been used. Tenotomy; plaster-of Paris dressing; apparatus. Walked with crutches at the end of six weeks, with cane at the end of seven months, and is still improving.

CASE V.—A. M., ten years of age; has never walked since an attack of infantile paralysis at one year of age. Hips and knees in fair condition; talipes equino-varus of left foot; equino-valgus of right foot.

Section of tendo Achillis and of the contracted fascia on the left side, and of the same tendon and of perineals on the right; plaster-of-Paris dressings; apparatus in five weeks. At the end of five months walking without cane and without fatigue for several blocks.

CASE VI.—R. C., three years old, has never walked, except upon all-fours, as shown in Fig. 3. Flexion at right angle. Section as described. Can now walk on crutches, and is gaining strength.

Fig. 3.

CEREBRAL SPASTIC CASES.

I am confident that in these cases the benefit to be derived from locomotion is not to be gained by any other means. The effect upon the physical well-being is marked; mental development occurs and is assisted by bringing the individual into contact with the world, an effect that should not be underrated. Some may say that brain-cells cannot be replaced. This is certainly true, but, as in a case of enfeebled muscles, constant exercise tends to stimulate growth and development. This action may be described as a benefit to be derived from without inward, but it is nevertheless positive. That it can produce a fully developed mind no one claims, nor can fully developed muscles be secured, but at the same time the gain derived is positive and decided.

The most common deformity in spastic cases is flexion of hip and knee, with contraction of the gastrocnemius and soleus. Adduction of the thigh is also frequent. All the deformities increase greatly as soon as the patient stands upon his feet.

In dressing these cases, I usually over-correct the equinus, them apply gypsum bandages to retain it in this position. The knee is then rigidly fixed in a straight line, and a continuous dressing from feet to perineum is applied. This permits complete and perfect abduction, to be secured by simply separating the feet.

After myotomy of the tensor vaginæ femoris and fascia, the weight of the plaster-cast is usually sufficient to lessen the hip-flexion, but weights are sometimes necessary. The hip-flexion is the one most liable to relapse when the upright position is resumed; hence I often use the wheel-crutch for a time, in order to take off the weight of the body.

Apparatus for these cases is often very complicated and expensive, and even then insufficient. I have long tried to secure a wheeled support for these unfortunates, but all those in the market are so expensive as to place them far beyond the reach of a large number of sufferers. With the valuable and helpful assistance of Dr. George E. Shoemaker, I have now constructed such a support that is both practical and cheap. To save expense we must use material that is already in the market. The running-gear of baby-coaches, or of children's express-wagons, or buckboards are utilized. These can be procured at from four to six dollars a set. For young children, or for those so feeble-minded or feeble-muscled as to require attendants, a baby-coach running-gear frame can be utilized so that it can be guided or pushed.

Upon the frame is erected a crutch-support. The crutch-head can be raised or lowered by a nut and thread. Jar is prevented by rubber washers. The width of the crutch-heads will vary with the diameter of the thorax. For very helpless cases a broad supporting belt of leather encircles the chest. For children who are strong and able to control themselves, the hind wheels are similar to the fore ones, but the latter are pivoted, as in rolling-chairs, ward-carriages, etc., thus permitting movement in any direction.

In hospitals with long halls a longer apparatus with self-steering gear, as seen in the illustration, may be employed, and is very useful in educating patients to walk. When an infantile paralytic, say fourteen years old, has never been up on his feet, it is not to be expected, even for a long time, that he will know how to use his feeble muscles. In spastic cases, many who cannot walk at all without this apparatus can by its aid make very comfortable progress.

The following are illustrative cases:

Case I.—Cerebral spastic paralysis from birth. Walks on tips of toes; toes inverted in position of talipes equino-varus; knees, thighs, and adductors flexed; moderate degree of mental impairment; marked internal strabismus; cannot walk without support, and then with the usual staggering gait.

Section of the tendo Achillis and of the adductors. Knees forcibly straightened and retained by plaster-of-Paris dressing from toes to perineum; limbs widely parted and fastened; apparatus applied. In six weeks heels well down upon the floor, although still pigeon-toed.

Case II.—G. B., nine years of age. Very low degree of mental development; unable to talk, but

can articulate a few words; unable to stand except with support. When voluntary motion is attempted, hips, arms, and legs are in a state of constant spasm.

Tenotomy of the hamstring tendons and tendo Achillis both sides; extension in bed. Wheel-crutch constructed so as to be pushed by a nurse like a baby carriage. In this manner patient is able to progress with much less spasm, and can bear considerable weight on his legs. No improvement in mental condition anticipated.

CASE III.—L. L., one year of age. Suffered injury by forceps at birth. No decided depression discovered in skull; very feeble intellect; can only stand when supported; talipes equinus in both feet.

Section of the tendo Achillis. Put upon a wheel-crutch at the end of six weeks, and with the aid of a nurse could walk with much comfort and pleasure.

CONCLUSIONS.—1. The deformities of infantile paralysis can be prevented by apparatus, but if this has been neglected and distortion has occurred, secure the best possible limb by immediate surgical procedures, and in some way make the patient walk.

2. Apparently hopelessly distorted cases can be put upon their feet. Even great deformity of limbs resulting from infantile spinal paralysis should not deter us from the attempt to straighten the limb and give the individual the power of locomotion.

3. Atrophied limbs can be straightened and can then be incorporated as a part of the locomotive apparatus.

4. Exercise is capable of developing even badly shrunken limbs, and continuous improvement may be expected.

5. In the majority of cases, easier, quicker, and better rectification is secured by surgical than by mechanical measures. In order to avoid pain and save time, immediate rectification, if possible, should be the rule.

6. After straightening, mechanical appliances in the shape of apparatus, canes, crutches, wheeled crutches, etc., are usually required and should be employed.

7. Tenotomy and myotomy do not cure the disease in either form of paralysis, but the results are most helpful in promoting the health and happiness of the individual.

8. Wheeled crutches are very helpful in getting these helpless individuals upon their feet. These supports can be made of inexpensive material and on a simple plan.

9. In spastic cases relapse is much more common than in infantile paralysis, but the great benefit to the body and mind of the individual that is secured by locomotion amply repays for the attempt at rectification.

THE DIAGNOSIS OF CEREBRAL HEMORRHAGE.[1]

BY AUGUSTUS A. ESHNER, M.D.,
INSTRUCTOR IN CLINICAL MEDICINE IN THE JEFFERSON MEDICAL COLLEGE AND IN THE PHILADELPHIA POLYCLINIC; REGISTRAR IN THE NEUROLOGICAL DEPARTMENT OF THE PHILADELPHIA HOSPITAL.

"OF all the diagnostic problems presented to the physician," says Gowers, in his work on *Nervous Diseases*, "that of cerebral hemorrhage is at once the most difficult and urgent." The diagnosis is simplified if recovery from the acute manifestations occur. It is in the grave and fulminant cases that the diagnosis is most difficult, and it is just in these cases that it is most important. Nothnagel, in *Ziemssen's Cyclopedia*, states that "the diagnosis, of hemorrhage or of embolism or of thrombosis cannot in any case be unreservedly made." With these qualifications let us endeavor to summarize and arrange side by side the special features that distinguish cerebral hemorrhage from those conditions that may simulate it. To no condition more than to cerebral hemorrhage applies with emphasis the statement that there are few pathognomonic signs in disease. Among other causes, the symptoms in this condition are due to the results of pressure, suddenly induced, and to destruction of cerebral tissue. Any other state, in which like influences are active, will be attended with similar manifestations.

In a consideration of cerebral hemorrhage all the forms of intra-cranial extravasation of blood are sometimes included. All display many symptoms in common, but there are certain features that, when present, distinguish the one from the other.

Let us first briefly pass in review the more common symptoms of intra-cranial hemorrhage. The two most prominent and characteristic are loss of consciousness and impairment of motion. Either may be present in varying degree. The second may not become evident until the first has passed away. The loss of consciousness may occur suddenly—constituting the so-called apoplectic shock—or it may set in gradually. It may be transient or protracted, and of an intensity from the slightest to the most profound. There are no true prodromata, except in cases of ingravescent apoplexy, in which the hemorrhage takes place gradually. So-called prodromata are usually due to the existence of the conditions favorable to the production of hemorrhage or to the occurrence of minute capillary hemorrhages.

In the attack, the breathing is usually slow, labored, noisy, but it may be rapid and shallow. The face is apt to be flushed, but it may be pale. The pulse is often slow, hard, and full, but it may be weak, rapid, and irregular; the carotids

[1] Read before the Northern Medical Association, June 12, 1891.

may pulsate. The pupils may be dilated or contracted, perhaps unequally, but they are usually sluggish or immobile. Perhaps even during the coma some difference between the muscular tone on the two sides of the body may be detected. The reflexes may be absent or exaggerated, but they are likely to differ on the two sides. Control of the sphincters may or may not be lost. Convulsions may occur, but are uncommon. There may have been nausea and vomiting. The head and eyes are usually turned from the side on which the paralysis occurs and toward that on which the lesion exists. The patient may die without emerging from the coma. Should consciousness return, the loss of muscular power becomes more evident. The temperature during the initial stage was perhaps subnormal, but now rises several degrees above the normal. The general symptoms gradually ameliorate, and in the course of several months there remain only those dependent upon the direct injury that the brain has suffered. The paralysis is usually of the hemiplegic type. The leg, arm, and face are paralyzed on the side opposite when the lesion is situated above the decussation of the fibers of the facial nerve, at the middle of the pons. The tongue, protruded, deviates to the paralyzed side. The lower part of the face is affected. The orbicularis palpebrarum and the occipito-frontal muscles are not involved. The face is drawn to the unparalyzed side, the angle of the mouth droops, and saliva dribbles. If the lesion is situated in the lower half of the pons the facial fibers are affected on the same side as the lesion, and the leg and arm on the opposite side. The asymmetry is evident when an attempt is made to pucker the lips, as in whistling, or in showing the teeth. Emotional movements, however, are symmetrically performed. Gradually there is some restoration of function, greatest in degree in least specialized parts and in those that participate in bilateral movements. The knee-jerk is exaggerated. Associated movements occur. Mental deterioration sets in.

The diagnosis would be easy if every case presented such a complete clinical picture; but in individual instances the symptoms are present in varying degrees of completeness. Again, cases are not always seen from the onset, and the history is frequently wanting.

In making the differential diagnosis cases of cerebral hemorrhage are to be separated: 1, from disorders due to intra-cranial lesions; 2, from conditions due to remote pathological changes. The distinction is further to be made from affections that for the want of a recognized lesion are called functional, such as epilepsy and hysteria. Probably in all of these conditions the symptoms arise from influences acting upon the cerebral cells and structure, but, on the one hand, the impression is direct and local, while, on the other, it is transmitted through the circulation as a result of changes extraneous to the cranial cavity. Let us first consider the latter.

Uremia may set in with convulsions, followed by coma. Convulsions are not common in cerebral hemorrhage. If they occur at all, they are more apt to appear late rather than as the initial symptom of an attack. As a rule, the coma in uremia is not so profound as in hemorrhage, though, as already stated, in the latter it may be of any degree of intensity. The existence of Bright's disease may have been known prior to the attack, or albumin and tube-casts may be present in the urine, but as the conditions present in Bright's disease are predisposing factors in the causation of cerebral hemorrhage, too much stress cannot be laid upon these points; besides, it is recognized that albumin appears in the urine in cases of cerebral hemorrhage uncomplicated with disease of the kidney. The temperature is at first apt to be low in uremia, as in hemorrhage, but there is no secondary elevation, unless there be a complicating inflammation.

Cerebral edema may be associated with a uremic attack, and give rise to motor symptoms, but, should the patient rally, these prove but transitory. Ophthalmoscopic examination may reveal the existence of an albuminuric retinitis. In uremia, the writer has observed that the breath and body have a peculiar musty odor, not encountered in cerebral hemorrhage.

In diabetic coma, in contradistinction to cerebral hemorrhage, the loss of consciousness is not abrupt. It may set in with somnolence. The pulse is weak and rapid. There is no paralysis. The breath may exhale an odor resembling chloroform. Then, an examination of the urine reveals the presence of sugar, while other manifestations of diabetes may also be evident.

In alcoholism the diagnosis may be embarrassed by many doubts. Examination of the urine may detect the presence of alcohol. Anstie's test consists in the production of a bright emerald-green color by the addition to fifteen minims of urine of one part of a solution of one part of chromic acid in three hundred of sulphuric. The patient, however, may have been drinking when the hemorrhage occurred, or stimulants may have been administered with the onset of the attack. The absence of the odor of alcohol in the breath and the absence of alcohol in the urine are more significant, and strengthen the probability of the existence of hemorrhage. Indulgence in alcohol, too, is an exciting cause of hemorrhage into the brain. In the stupor from alcoholism, however, the patient can be aroused by appropriate stimuli, as by ammonia or by shouting. The pulse is soft and rapid,

there is muscular relaxation, but no paralysis, and the reflexes are not altered from the normal. The pupils are dilated, the conjunctivæ injected. The temperature may be subnormal, but there is no secondary fever. Recovery, should it take place, is comparatively rapid, and may be facilitated by inhalations of ammonia or by evacuating the contents of the stomach and bowels. Edema of the brain may be present, as in uremia, increasing the difficulty of diagnosis.

In opium-poisoning the coma occurs gradually, the pupils are small, but equal, the breathing is feeble, shallow, and infrequent, and there may be vomiting. The patient, however, can be aroused, and he responds to stimuli. There is no paralysis, no elevation of temperature. If no complication exists, under appropriate treatment the return to the normal condition is rapid.

In poisoning by chloroform or by hydrocyanic acid, the odor of the breath is distinctive. In the first the heart's action is rapid and tumultuous, the pupils are dilated, and there is general anesthesia. In the second, inspiration is peculiarly short, and expiration is prolonged and labored. In the case of both, the sequelæ of cerebral hemorrhage are wanting.

In asphyxia, from whatever cause, the breathing is embarrassed, and there are all the evidences of respiratory obstruction. The face is livid and congested. Convulsions and coma ensue, and if the cause be not removed death follows. The symptoms are general, not local or unilateral.

In syncope and in cerebral anemia the conditions are much alike. The face is pallid, the pulse is rapid, feeble, fluttering, the respiration is sighing, the extremities are cold, and there may be nausea and vomiting—all of which may be improved by the exhibition of stimulants.

Cerebral congestion may be owing to fulness of the veins due to obstruction, or to deficient *vis à tergo*, or to fulness of the arteries from cardiac overaction. Should loss of consciousness occur it is of but brief duration, or only partial. Loss of power is slight or absent, and not lasting, while there are no variations of temperature and the symptoms are speedily recovered from. Most probably there have also been previous attacks of the same kind.

The facial palsy resulting from cerebral hemorrhage is to be distinguished from paralysis of the muscles supplied by the facial nerve as a result of disease of the nerve or of its nucleus, by the escape of the orbicularis palpebrarum and the occipito-frontal muscles; by the fact that associated and emotional movements of the face are symmetrically performed, and that atrophy and degenerative reactions do not follow.

Hemorrhage into the cord or spinal apoplexy also occasions paralysis, but usually in the form of paraplegia. It is most apt to occur in the young, with a history of syphilis. The patient feels a sudden, sharp, stinging pain in the back. There is no loss of consciousness, or should there be it is but passing. If the hemorrhage is into the membranes, there will be tonic convulsions of a tetanic character.

Epilepsy ought not to be confounded with cerebral hemorrhage, but, seen in the stage of unconsciousness, some doubt may arise. The diagnosis of convulsions symptomatic of intra-cranial disease is intimately connected with a recognition of the exciting cause. In so-called idiopathic epilepsy convulsions precede coma, the tongue is apt to be bitten, there is no paralysis, the temperature may be elevated, but it is not at first depressed, and there is a history of previous attacks.

Sunstroke occurs at a particular season of the year, during the heated term. If cerebral hemorrhage shows any preference for season, the larger number of cases in this climate occur in the spring. In sunstroke the temperature is from the outset high, at times exceedingly so, and the skin is dry and burning. Coma is ordinarily not protracted or profound. Headache and vesical disorders may be sequelæ—paralyses never.

It can be readily enough conceived that symptoms of cerebral hemorrhage may develop in an hysterical person; but one ought not to be deceived if he bear in mind the age of the patient, the sex, and perhaps a known menstrual derangement. A discriminating eye will be able to distinguish the feigned attack from the genuine one. On the other hand cerebral hemorrhage may occur in an hysterical individual, and the manfestations of the one should not be permitted to obscure the more grave condition.

The distinction of cerebral hemorrhage from other pathological intra-cranial conditions divides itself into the differential diagnosis of the various kinds of hemorrhage, with some reference to their location, the separation from vascular obstruction and that from other varied conditions.

Should abscess of the brain give rise to loss of consciousness, this is apt to have been preceded by other symptoms. A cause for an abscess may be found in some previous injury or contiguous inflammation, or a general pyemic condition. Chills, fever, and sweats are apt to have occurred, perhaps with symptoms of pressure. Hemorrhage may take place into an abscess, adding its own peculiar symptoms to those previously existing.

Hemiplegia or local palsies may result from tumors of the brain. These are most commonly gliomata, gummata, or tuberculomata. Their favorite situation is at the base. They are marked by intense headache and papillitis, the symptoms are slow

in onset and progressive in course, so that if loss of consciousness occurs and manifestations of an apoplectic seizure appear, they do so in the last stage of the disease. Convulsions may also occur. The existence of tumors in other parts of the body may afford material aid in the recognition of a growth in the brain.

Concussion of the brain, contusion, laceration, and compression, result from varying degrees of violence and present gradations of cerebral disturbance. Concussion occasions the symptoms of mild shock: pallid face, weak pulse, shallow respiration; the symptoms are of brief duration, unattended with the sequelæ of hemorrhage. Contusion and laceration are conditions difficult to recognize and present symptoms varying in intensity from those of concussion to those of hemorrhage. In compression, there are present conditions that give rise to some of the manifestations of hemorrhage. In all of these the diagnosis essentially depends upon the recognition or the knowledge of the antecedent causative agency.

Meningeal hemorrhage may result from traumatism or from the bursting of an aneurism; it may be a complication of thrombosis of a cerebral sinus; it may occur in infectious diseases and in general paralysis of the insane. In the newborn, it is caused by violence during labor, from the application of the forceps, or by compression of the head in its passage through a narrow birth-canal. It is doubtful whether or not it is the more common in head-last labors. In these cases of birth-palsy, the manifestations of the lesion may not become apparent until later in life. A considerable number of cases of spastic paraplegia, congenital chorea, epilepsy, and idiocy are related to this condition. They may be recognized by the fact that the manifestations are not progressive, but stationary, and that there is no history of onset subsequently to birth. As a rule, the symptoms attending meningeal hemorrhage in adults are almost identical with those of extensive intra-cerebral hemorrhage. It may be that the paralysis is more extensive, involving perhaps all four extremities. The diagnosis largely depends upon a knowledge of the preëxisting condition (aneurism) or upon a history of injury.

In cerebral embolism, the diagnosis is based upon the existence of an endocarditis, of valvular vegetations, or of vascular atheroma or other source of embolus, upon the suddenness of onset, upon the transitory character of the symptoms, the limitation of the local manifestations, and the frequent occurrence of aphasia, together with right-sided hemiplegia. Convulsions are more common in embolism than in hemorrhage. There may be vomiting and transitory delirium. The younger the patient, the stronger the probability of embolism. The recognition of emboli in other organs strengthens the diagnosis. Among the causes of occlusion of the cerebral capillaries are pigment emboli, occurring in malaria, fat emboli, leucocytes, fibrinous formations, lime deposits, and intra-vascular conditions.

Thrombosis may occur in the arteries, veins, or sinuses of the brain. It may arise in conditions of general debility, from cardiac weakness, in blood dyscrasiæ, in vessels narrowed by atheromatous or fibroid disease, or by compression from without. The symptoms are gradual in onset and progressive in course, and vary with the site of obstruction. Following are some of the points of distinction from hemorrhage: Thrombosis is more apt than hemorrhage to occur in extreme old age; considerable degeneration of the arteries of the extremities is likely to be present; the heart is dilated, its action feeble and irregular; in hemorrhage the arterial tension is usually high, and the strongly acting heart is hypertrophied, retinal hemorrhage may also be present; thrombosis is more commonly associated with depression, hemorrhage with excitement; thrombosis is attended with prodromata and there may be local convulsions; should convulsions occur in hemorrhage, they are general; in hemorrhage, the loss of consciousness is more profound and of longer duration than in thrombosis; Jacksonian epilepsy and amaurosis may follow upon vascular occlusion; when death occurs it is not apt to be so sudden as in hemorrhage, while recovery may be complete. The clinical results, however, of softening and of hemorrhage may be identical.

Obstruction of certain vessels of the brain gives rise to special symptoms. Thus in thrombosis of the longitudinal sinus the face is apt to be cyanotic, from distention of the facial veins, or there may be epistaxis. In thrombosis of the transverse sinus, there may be edema of the structures about the external ear and mastoid process. Obstruction of the cavernous sinus may give rise to hyperemia of the optic disc, to edema of the eyelids and injection of the conjunctivæ, and to paralysis of the third, the fourth, the ophthalmic branch of the fifth, and the sixth nerves. Thrombosis of the basilar artery occasions symptoms resembling those due to tumor of the pons Varolii: epileptiform convulsions, optic neuritis, high temperature, crossed paralysis.

Finally, let us make brief reference to some manifestations peculiar to hemorrhage in certain locations.

Hemorrhages into the corpus striatum, into the lenticular or the caudate nucleus are attended with motor paralysis of the face and body on the side opposite to that on which the extravasation occurs, without any alterations of sensation.

Hemorrhages into the optic thalamus occasion no motor manifestations. Lesions in certain specified

regions cause decided and permanent anesthesia, with elevation of temperature upon the opposite side of the body.

Hemorrhages into the cortex set in with convulsions. These, with the attendant sequelæ, are focal in character. Extravasations into the anterior lobe may be attended with loss of the sense of smell upon the same side.

Hemorrhages into the crus cerebri are likely to be associated with paralysis and anesthesia of the limbs on the opposite side of the body and paralysis of the third nerve on the same side as that on which the lesion occurs. The crura, however, are rarely affected alone, and the symptoms will be merged with those resulting from involvement of other parts.

There is much similarity between the symptoms of hemorrhage into the pons and those of hemorrhage into the medulla. In both the temperature soon rises unusually high, the coma is profound, and death is commonly rapid. In hemorrhages involving the pons, initial convulsions are frequent and are usually general, though sometimes affecting only the legs. Often there is anesthesia. The pupils are markedly contracted and immobile. Vomiting is frequent and there is marked disturbance of the respiration. There is paralysis of the extremities on one side and of the face upon the same or opposite side, or upon both sides.

In hemorrhages into the medulla there may be diabetes, insipidus or mellitus, and paralysis of the tongue.

Convulsions are also present in hemorrhages into the ventricles. They may be exclusively tonic, or tonic and clonic. There is deep coma, soon followed by death. Such hemorrhages are common in the extremely young and extremely old.

The corpora quadrigemina are never alone involved in hemorrhage. Such symptoms as amaurosis, immobility of pupil, muscular tremblings, and convulsions might be present in case of their involvement.

In hemorrhage into the cerebellum there is often no initial paralysis. Sometimes there is hemiplegia on the side of the lesion. The absence of paralysis, however, is of more significance than its presence. Loss of consciousness may have been but temporary. Vomiting is frequent and persistent. There is incoordination of muscular movement and there may be compelled movements. Amblyopia, amaurosis, and mydriasis may be present.

In the preparation of this paper the works of Nothnagel, Fagge, Strümpell, Gowers, and Da Costa have been freely drawn upon.

THE TREATMENT OF ABSCESSES OF POTT'S DISEASE.[1]

BY W. R. TOWNSEND, A.M., M.D.,

ASSISTANT SURGEON TO THE HOSPITAL FOR RUPTURED AND CRIPPLED; ORTHOPEDIC SURGEON, NEW YORK INFANT ASYLUM; CONSULTING SURGEON, BAYONNE HOSPITAL; LECTURER ON ORTHOPEDIC SURGERY, NEW YORK POLYCLINIC.

THE proper treatment of the various complications of any disease is a matter of fully as great importance as the treatment of the disease itself, and while opinions vary but little as to how to treat Pott's disease, such is not the case with respect to the abscesses that are such a frequent complication. Some recommend that every abscess be let alone, others that every abscess be opened. To follow blindly either extreme is certainly not good surgery, and with an endeavor to throw some little light upon the subject, I have studied during the past summer the histories of 380 consecutive cases of Pott's disease seen at the Hospital for the Ruptured and Crippled, New York, and in the private practice of Dr. Gibney and myself. In speaking of the cases no distinction is made between hospital cases and those in private practice, as the conditions varied so little. I have purposely omitted complicated cases, as of Pott's disease with hip, or knee, or ankle lesions.

Of the 380 cases, 75 were complicated by abscesses, and as the cases represented all stages of the disease, from the incipient case in which a positive diagnosis was scarcely possible to those that were convalescent and cured, we may say that about one case in five at some time during the disease develops an abscess. These figures vary somewhat from those given by Mohr, quoted by Bradford and Lovett, according to which, in 61 autopsies, there were 30 with abscesses, and in life, of 72 cases, 9 with abscesses. The abscesses were found connected with disease in the cervical region in 8 per cent. of the cases, in the dorsal region in 20 per cent., and in the lumbar region in 72 per cent. of the cases, which figures very closely correspond with those given by Michael and Parker.

We see by the foregoing that the problem most frequently presented to us is the treatment of abscesses connected with the lumbar region, and fully two-thirds of these are either in the pelvis above Poupart's ligament, or pass below the ligament and point in the thigh through Scarpa's triangle—the psoas abscesses.

Of late years the study of bacteriology has largely increased our knowledge of diseased processes, and shown that true inflammation is always caused by the presence of one or more kinds of pathogenic microbes. In other words, in acute abscess we find

---

[1] Read at the meeting of the American Orthopedic Association held in Washington, September, 1891.

pus-microbes; in a cold abscess, however, such is not the case, and I will quote briefly from Senn, *Principles of Surgery*, page 450. Speaking of tuberculous abscesses, he says: "The effect of the bacillus of tuberculosis on the tissue is to produce a chronic inflammation, which invariably results in the production of granulation-tissue. The embryonic cells furnish, as it were, a wall of protection for the surrounding healthy tissue. The characteristic pathological feature of every tuberculous product consists in the tendency of the cells of which it is composed to undergo early degenerative changes, which are caused by local anemia and the specific chemical action of the ptomaïnes of the tubercle-bacilli, and consists in coagulation-necrosis, caseation, and liquefaction of the cheesy material into an emulsion, which has always been regarded as pus, until recent investigations have shown that it is simply the product of retrograde tissue-metamorphosis, and not true pus. I believe that it can now be considered as a settled fact that the bacillus of tuberculosis is not a pyogenic microbe, and that in the absence of other microbes it produces a specific form of inflammation which invariably terminates in the production of granulation tissue, and that when true suppuration takes place in the tuberculous product it occurs in consequence of secondary infection with pus-microbes."

Accepting the pathology as given, the treatment of the abscesses of Pott's disease seems to me more simple than some would have us believe. If the abscesses could be opened, thoroughly cleansed, all tuberculous material removed, any bone-detritus washed away, with no infection of the external tissues, and with perfect asepsis, then those who advocate opening every abscess would clearly have established their point; on the other hand, could it be shown that no trouble followed from extreme conservatism, then there would be no necessity for operative procedures. But whilst some cases do well, and the abscess seems in no way to influence the final result, others do badly, and the abscess is undoubtedly the cause of the patient's death. The explanation of these various conditions seems to me to be largely due to the question of infection by the pus microbes. As long as the tuberculous or cold abscess remains purely such, but little inconvenience may result to the patient and the symptoms are insignificant; but let a mixed or a secondary infection occur, and all is changed; a condition of sepsis is added to one of tuberculosis. If the abscess has never been opened, it is noticed that the child is doing poorly, septic symptoms appear, the temperature is characteristic or at least suggestive, more severe symptoms may follow, and, if nothing is done, death ensues; but let such a case be treated scientifically: remove or do away with the source of infection, secure proper drainage, and improvement will at once be noted. The secondary infection may not occur until some time after the abscess has been opened, or it may occur at the time of opening, and it is the danger and the great frequency of this occurrence that deters us from opening these cold abscesses. We know that despite all possible precautions, and with every endeavor to be strictly and surgically aseptic, the cases become infected, and may die as a result of this infection. If the septic trouble be mild in character it is usually recovered from, but we must remember that the patient is already suffering from tuberculosis, and the conditions are not as favorable as they would otherwise be.

Caseation and absorption of the liquid contents of the abscess are a more frequent result, I believe, than is generally supposed, and this may often be aided by means of aspiration, which, of course, is done with every antiseptic precaution. The operation is often very disappointing, owing to the fact that the needle soon becomes clogged and the abscess is but very imperfectly evacuated. This difficulty can be partly overcome by using a large-sized needle, through which, if the suction-force is good, large pieces of cheesy material may be removed; and a simple expedient that I have found of value when such clogging does occur is to force through your aspiratory needle a small amount of a weak carbolic solution, thus washing back into the cavity the obstructing plug, then, changing the position of the needle, to begin aspirating again. Introduce the needle at some little distance from the abscess, so that considerable tissue intervenes between the opening and the external air. It is advisable to make the openings also at dependent points, so that if the abscess should eventually open along the track of the needle the drainage will be of the best. If possible, after the evacuation of the abscess, whether or not any fluids, such as iodoform and glycerin, or hydrogen peroxide, etc., have been injected, make pressure either by a pad and bandage, or by straps of adhesive plaster. This prevents hemorrhage from the sac-walls, and promotes absorption. Very little has been done with the injection of fluids into the abscess-cavity after evacuation in the cases here analyzed, as the results by the other method were so good. The iodoform-emulsions suggested by Bruns and Krause, seem, however, worthy of trial.

In all cases, no matter at what stage of the disease, efficient protection should be given the spine, either by plaster, paper, wooden or wire jackets, or corsets, or by some of the numerous forms of braces. This protection, combined with proper general care of the patient, will in many cases cause a disappearance of the abscess, and all that remains is a small nodule,

without fluctuation, and causing no symptoms. If the abscess is increasing rapidly in size, or is producing pressure-symptoms, aspirate, and this should be continued at intervals if the patient is doing well. If the patient is doing poorly, and symptoms indicate that this is due to the abscess, endeavor to remove the cause; open, clean out thoroughly, scrape the abscess-cavity, and, if possible, the sinus leading to the diseased bone, and also the diseased bone itself. Secure good drainage, and keep your wound aseptic, if possible. Of the many cases of abscess in the pelvis but few can be properly drained by one opening, and I believe it best to open through and through so that, standing or lying down, the drainage is always good.

Whether the cheesy mass left behind after non-operative treatment or after aspiration may cause future trouble, is a matter that is not clearly established, although we might reasonably suppose that in some cases it does.

There are also a certain number of cases in which aspiration or incision might be indicated to prevent the abscess bursting into some viscus, but none have occurred among those analyzed in this paper. The most frequent indications for opening the abscess in non-infected cases that are doing well are that they interfere with the proper application of a brace or, by their size, are impediments to locomotion. The psoas abscesses, if accompanied by much contraction of psoas and iliacus muscles, cause marked lameness, which disappears when the abscess is removed. Another reason for aspiration or incision is that, by burrowing, the abscess may enter another joint and cause further trouble.

ANALYSIS OF 75 CASES OF ABSCESSES OF POTT'S DISEASE.

No treatment but brace;	abscess disappeared	3

Deaths.

Tuberculous meningitis	2
Amyloid liver	2
Suppression of urine	1
	5

A study of the preceding analysis will show us that the cases that have been treated on the expectant plan and by aspiration have done remarkably well, and we believe this plan should be followed whenever possible. The two deaths from meningitis occurred in cases that had been aspirated, the two from amyloid liver in cases that had opened spontaneously, and the death from suppression of urine occurred in a child thirty-six hours after opening a psoas abscess in front and behind and inserting a drainage-tube. These results are immediate rather than final, and it must be clearly understood that they do not represent the true death-rate of Pott's disease complicated by abscesses. The death-rate after incision is also larger in adults than in children.

THE FUNDAMENTAL PRINCIPLES OF ANATOMICAL NOMENCLATURE.[1]

BY BURT G. WILDER, M.D.,
PROFESSOR OF PHYSIOLOGY, COMPARATIVE ANATOMY, AND ZOÖLOGY IN CORNELL UNIVERSITY, ITHACA, N. Y.

THE late honored President of the Association of American Anatomists,[2] in the preface to the second edition of his treatise on *Human Anatomy*, published less than three years ago, wrote as follows:

"As a rule, one name for an organ or part is used, and that one selected which is simplest and most expressive of its character.

"The name also, so far as may be permitted, is rendered into English.

"Many phrases in common use as names have been curtailed of what have appeared unnecessary portions, and sometimes the adjective portion of the phrase has been retained in preference to the substantive portion, where, for various reasons, it has seemed more appropriate.

"Where names of persons are applied to parts, they are generally avoided, and others, in all respects better adapted to the purpose, are used.

"A radical change would confuse, rather than facilitate, the study of anatomy."

It is not easy to determine what quality of this announcement is most impressive: the brevity and simplicity with which a complex subject is stated; the judicial and impersonal attitude respecting what too easily lends itself to controversy; the moral courage displayed by one naturally conservative and no longer young in adopting certain new "tools of thought"

[1] Read at the meeting of the Association of American Anatomists, held in Washington, September, 1891.

[2] Professor Joseph Leidy, M.D., LL.D.

in place of some that he had used and taught others to use for more than a quarter of a century; or, finally, the practical wisdom that led him to deprecate, as both needless and harmful, any sweeping re-designation of anatomical parts.

The following selections from the names used by Dr. Leidy for parts of the brain may illustrate the nature and extent of the modifications sanctioned by him, and serve as the basis for a brief further consideration of the more important principles involved:

Callosum for "corpus callosum," or "trabs cerebri."

Central fissure for "fissure of Rolando."

Chiasm for "chiasma opticum," or "chiasma nervorum opticorum."

Dura for "dura mater."

Fimbria for "corpus fimbriatum," or "tænia hippocampi."

Hippocampus for "hippocampus major," or "cornu Ammonis."

Oblongata for "medulla oblongata."

Pons for "pons Varolii."

Thalamus for "thalamus opticus," or "thalamus nervorum opticorum."

The parts designated are among those most frequently mentioned in discussing the anatomy of the brain; with them, therefore, is there most need of terminological simplification.

In one sense they are new names, but in another and more important sense they are merely familiar terms in a more convenient form.

Most of them are sufficiently appropriate etymologically, *e. g.*, *chiasm*, *fimbria*, *pons*. Some may not be superior in themselves, but are so linked with the accepted names of other parts as to have an indirect claim to perpetuity; from *hippocampus* was named the hippocampal fissure; the physiologically-interesting paracentral lobule was so called from its topographical relation to the central fissure; the great cerebral commissure might be more fitly indicated by *trabs*, a beam, than by *callosum;* but the latter word is, as it were, embalmed in *callosal* and its several compounds.

The words are euphonious, easily pronounced, and of moderate length—none over four syllables; as mere verbal forms, therefore, they are acceptable.

The words are all Latin in form, or at least in immediate derivation. Hence no national jealousies can arise, and hence, also, the name may be adopted into any modern language by the well-established methods that have been enumerated in some detail by the writer.[1]

For example, the Latin *fissura* becomes *fessura* in Italian, *fissure* in English and French (the two distinguished by pronunciation, though not in spelling), and *Fissur* in German. Each of these is a paronym of the original Latin, and from each may be formed the appropriate adjective.

From the substantives adjectives are regularly derived; *fimbrial*, *hippocampal*, and *thalamic* are beyond question; there may be room for choice between *chiasmal* and *chiasmatic*, according as one is governed by practical or classical considerations; the adjective from pons is certainly *pontile*, rather than *pontal* or *pontine*.

Callosum, *dura*, *pia*, and *oblongata* are already Latin adjectives, but that is no obstacle to the formation of secondary adjectives from them. *Callosal*, indeed, is one of the commonest of encephalic terms; *dural* and *pial* are not infrequent, and *oblongatal* has been employed.[1]

With the exception of *central fissure*, all are mononyms, or single-word terms; there is but one compound, *hippocampus*, and there are no pseudo-mononyms, verbal tandems, so to speak, such as the Germans produce by stringing together an indefinite number of single words.

The two-word term, or dionym, *central fissure*, is an example of a large number of names of parts that constitute natural groups or series. The atlas and axis have special names, but most of the vertebræ, like the ribs, are merely numbered; among the arteries, the aorta only has a mononym; among the gyri or convolutions, the cuneus, precuneus, and operculum are so distinguished; all the fissures have double names, comparable with the generic and specific names of animals and plants.

But, as with *central fissure*, the distinctive part of the name is often a single word, a mononymic adjective, and most of the other fissures and gyri may be so provided by simple verbal combinations.[2]

It will be noted that, among the terms selected from Dr. Leidy's work, only two are distinctly English rather than Latin in form, viz., *chiasm* and *central fissure*; these are the Anglo-paronyms of

[1] "Paronymy *versus* Heteronymy as Neuronymic Principles," Journal of Nervous and Mental Diseases, xii, 1885; "Anatomical Terminology," Reference Handbook of the Medical Sciences, viii, 1889.

[1] In the descriptions of the structure and functions of the two kinds of nervous tissue given in the larger treatises on Physiology, *e. g.*, that of Foster, how much space would be saved and how much wearisome repetition avoided were *alba* and *cinerea* to replace *white matter* and *gray matter*, and *albal* and *dural* the phrases commonly employed.

[2] In 1885 (*New York Medical Journal*, November 25th), the writer proposed that the commonly-accepted names for the encephalic arteries should be mononymized by replacing adjectives indicative of relative position by prefixes having the same signification; thus, *posterior cerebral* became *postcerebral*, etc. In his article, "Vessels of the Brain," in the Reference Handbook of the Medical Sciences, viii, Dr. William Browning has not only adopted these simplified names, but has applied the system to the veins and sinuses of the brain.

chiasma and *fissura centralis;* the others, as *spelled*, are either Latin or English. If intended to be regarded as Latin, then in an English page they should be italicized; but as English words they would be pronounced as such and be regarded as unchanged paronyms.

The change of Latin words by paronymy is what Dr. Leidy meant when he said that the names are "rendered into English." But there is another mode of rendering, namely, by translating into the vernacular; this would have given *bed* for *thalamus*, *bridge* for *pons*, *hard mass* for *callosum*, and *middle cleft* for *fissura centralis*. These heteronyms may be more or less acceptable as mere words, but they do not readily submit to the formation of adjectives; they rarely suggest the Latin equivalent, and are apt to be wholly unlike the corresponding vernacular terms in other languages. Heteronyms are incongruous and dissociating; paronyms are homogeneous and constitute substantial steps toward the realization of a universal scientific language.

Dr. Leidy's use of *fimbria* in place of *corpus fimbriatum* demands special comment, because it represents a group of cases in which the reduction of the polyonym to the mononym involves two distinct stages: first, the dropping of the superfluous *corpus*, leaving the neuter adjective to be used substantively, like *callosum*, *caudatum*, etc; secondly, the abandonment of the adjective in favor of the noun, *fimbria*, from which it was derived; this not only gives a shorter word, but warrants the shorter adjective, *fimbrial*. The principle is a well-established form of metaphor; it is as if a man with a lion-like head were called first *homo leontiformis*, then *leontiformis*, and finally simply *leo*, the context preventing confusion of meaning. Similarly there is no reason why *corpus lenticulare* should not become successively *lenticulare* and *lenticula; corpus restiforme*, *restiforme*, and then *restis*.

It will be remembered that Dr. Leidy's method of reducing polyonyms to mononyms was, to use his own language, by omitting superfluous words; the numerous terms beginning with *corpus* were thus lightened, literally disembodied, leaving only the spirit, the essential part. But he was not apparently prepared to convert into mononyms the very considerable number of polyonyms containing adjectives indicative of relative position, by replacing the adjectives with prefixes having the same meaning. Yet the general use of analogous compounds, for example, *prefrontal* and *postfrontal* for *anterior* and *posterior frontal*, and of *prencephalon* and *mesencephalon* for *anterior* and *middle-brain segment*, encourages the belief that in time, when the advantages of mononyms are more generally and fully recognized, there will be adopted not only Owen's *precava* and *postcava* in place of the ponderous *vena cava anterior* and *posterior*, or *ascending* and *descending vena cava*, but also many analogous names of groups of associated parts, *e. g.*, *precommissure*, *postcommissure*, *medicommissure; precornu*, *postcornu*, and *medicornu*. As Latin mononyms, all these and similar terms, while retaining the full and unmistakable significance of the original polyonyms—*commissura posterior*, etc., would gain the capacity for adjective inflection and for transportation into all modern languages without material change of form.

In brief, while honoring our anatomical predecessors by carefully regarding the terms they have transmitted to us, we should, with him who has so recently left us, bear in mind that the advancement and dissemination of our chosen science demands a simplification of its language, and we should accomplish this end, so far as practicable, by *the selection or formation of Latin mononyms, from which each nation may form the appropriate paronyms.*

Whatever principles or set of names we may adopt, there is a point of *practice*, respecting which the precept and example of Dr. Leidy are surely worthy of universal acceptance and imitation, viz., to use *only one name for an organ or part*, all others being synonyms. Even the accomplished anatomist is apt to be delayed by encountering two, three, or more names for one and the same part in different passages of the same book or article, while to the beginner it is simply bewildering. As long ago as 1885 Dr. Leidy had prepared lists of the names he thought of using in the new edition of his *Anatomy*, and the changes in detail did not prevent the maintenance of a terminological consistency which was nearly without precedent.

CLINICAL MEMORANDA.

REPORT OF A CASE OF ECTOPIC PREGNANCY.[1]

BY HENRY D. INGRAHAM, M.D.,
PROFESSOR OF GYNECOLOGY, MEDICAL DEPARTMENT NIAGARA UNIVERSITY; GYNECOLOGIST TO THE BUFFALO HOSPITAL OF THE SISTERS OF CHARITY.

MRS. A. E. P., twenty-four years old on November 5, 1890, was born in the State of New York. She menstruated first at the age of fifteen; was always regular, but suffered from dysmenorrhea until after the birth of her first child. She was married at the age of seventeen and a half years; has three children, the oldest five, the second nineteen months younger, and the youngest was one year old last December. She has had no miscarriages. Menstruation appeared regularly two months after the birth of the first child, but it was two years after the birth of the second child before its reappearance. The third child was one year old on the 16th of last December, and menstruation occurred for the first time on the 28th of that month, lasting three days, but being more pro-

[1] Read at the meeting of the Central New York Medical Association, held at Buffalo, N. Y., June 2, 1891.

fuse than normal. It appeared again on January 28th, the flow being normal. On February 28th she had a slight discharge which she thought was menstrual. While carrying the last child, after about the fourth or fifth month she had pain in the left iliac region, which was worse after the birth of the child, varying in intensity, but never entirely absent. About the 18th of last February she had the "grippe," the pains extending all over her body, but being more severe in the left side. She kept in bed for a week, after which she felt quite well, the pain in the left iliac region having nearly disappeared. Other than as already mentioned the patient never had any illness. Early in the morning of March 1st she walked one mile to assist at a confinement, being in her usual health. About 3.30 P.M. she was suddenly seized with severe pain in the left side, and fell to the floor, losing consciousness for a short time. When she recovered consciousness she felt very weak and faint, and suffered from severe pains in the abdomen, especially in the left iliac region. She described the pain in the abdomen as "terrible cramps." About an hour later she felt as though her bowels would move, and, when placed on the vessel, there was a slight movement. She fainted again, but soon rallied after being placed in bed. The desire to go to stool still remained, and vomiting occurred several times.

Dr. H. C. Buswell saw the patient one and a half hours after the attack, and found her as described, with a a very rapid, feeble pulse, and unable to raise her head. She was in a state of almost complete collapse. Dr. Buswell raised the foot of the bed, and used other restorative remedies. Vaginal examination revealed a soft, boggy mass, very tender to the touch, at the left and posterior to the uterus. There was also a slightly bloody discharge from the uterus. The diagnosis made by Dr. Buswell was ectopic pregnancy with rupture of the tube. In addition to what had already been done, morphine was administered to relieve the pain, and instructions were given to keep the patient quiet, and under no circumstances to allow her to raise her head.

The next morning she had rallied considerably, and was better in every respect. The same treatment was continued until the fourth day, when I saw the patient for the first time. I found the pulse 110, which was less frequent than it had been; the temperature was 100°. The pain and tenderness were so great that a thorough examination could not be made, yet the boggy mass at the left and posterior to the uterus could be felt. The uterus was two and three-fourths inches in depth.

I confirmed Dr. Buswell's diagnosis, and advised operation; but the husband being away, the patient wished to wait until his return. As she was improving, although slowly, and as the surroundings were the very worst, it was thought advisable to wait, carefully watching the patient, hoping that she might improve sufficiently to be moved to the hospital. She was kept quiet in bed; for two weeks her temperature was from 100° to 101°, the pulse from 100 to 110; abdominal tenderness was pronounced. At the end of two weeks the temperature was normal or nearly so most of the time, the pulse but little accelerated, yet the abdominal tenderness was quite marked, especially on the left side, and the patient was unable to sit up.

A week later, four weeks after the attack, she was removed to her mother's house, a distance of half a mile. After that she did not feel quite so well, with increased pain and febrile disturbance. For the next few days she was sometimes better, sometimes worse, the abdominal pain and tenderness, especially on the left side, being very pronounced; the pulse was rather frequent, from 85 to 90, but the temperature was nearly normal, though at times slightly raised. About April 7th she felt worse, and began to realize the force of what had been told her, that she could not get well without an operation, and on April 9th she was taken to the Buffalo Hospital of the Sisters of Charity. Up to the time of removal to the hospital I saw the patient only twice, the first time four days after rupture occurred and the next time three or four days later. The facts for the greater part of the foregoing history were furnished by Dr. Buswell, who, in addition to what I had already told the patient, explained the nature of the difficulty to her and urged the operation. But for several reasons, the principal being the absence from home of her husband, consent was not obtained until her removal to the hospital, more than five weeks after the occurrence of the rupture. After her arrival at the hospital she felt better than at any time since the rupture occurred. She was able to sit up and walk about her room and the corridors. Her appetite was good, there was no fever, and the secretions were normal, yet the left iliac region continued very sore and tender.

On April 13th, assisted by Drs. Buswell, Bentler, Colton, and Dowd, I opened the abdominal cavity and found on the left side nearly two quarts of débris, mostly clotted blood, which had the appearance of being about to suppurate. The tube of this side was ruptured in the outer half, the rent being quite large. The tube was ligated close to the uterus, and carefully removed, as was also the blood; some of this, however, was so firmly adherent to the intestines that many little particles were allowed to remain, as it was thought that their presence would produce less disturbance than would their removal. The right ovary was cystic, of the size of a hen's egg, the walls of the cyst being very thin and transparent, the fluid thin and colorless. This cyst ruptured during its removal. The abdominal cavity was carefully cleansed by sponging, but was not washed out, nor was drainage used. Reaction occurred promptly, and the patient did well, except that vomiting was very persistent, and continued fifty hours. She was carefully prepared for the operation, and, except several remedies that are supposed to control vomiting, nothing was afterward given but an occasional swallow of hot water, and later a little beef-tea, until vomiting stopped. In this case, if any medicine controlled the vomiting, it was coca wine. I think, however, that time did as much as, if not more than, all the remedies employed to relieve the vomiting.

The second day at midnight the temperature was 101°, the highest at any time, and the pulse 100. The third day at six o'clock in the evening the temperature was 100°, and the pulse 90. After that both temperature and pulse were nearly normal. The bowels moved on the third day, and every second day afterward. Convalescence was uninterrupted, and three weeks after the operation the patient left the hospital, saying that she felt better than she had in a long time. At this writing, five months after the operation, she feels better than at any time during the past two or three years.

I should state that in this case the fetus was not found, but the placenta was recognized. This is the sixth case that I have seen; five of them were operated on and recovered, and the other died before an operation could be performed.

Some of the points to which especial attention is called are these: This patient had not been sterile for any length of time, neither had she shown "a previous inaptitude for conception." There were none of the usual signs of pregnancy present, the patient not having the least idea that she was in that condition.

The feeling as though the bowels would move, which was present in this case, is said to be characteristic of rupture into the broad ligament of the left side.

Notwithstanding that the whole of both tubes and ovaries were removed, the patient continued to menstruate as regularly as ever and more profusely.

The point of especial interest is the fact that, although the rupture was intra-peritoneal, the patient did not lose her life from hemorrhage. Absorption of the blood and placenta did not take place, and to leave so large a quantity of foreign matter in the abdominal cavity any length of time is no doubt extremely dangerous. It is very fortunate that the only unfavorable consequence was the peritonitis from which the patient suffered.

The only case similar to this of which I have any knowledge is reported by Mr. Tait, in his *Diseases of Women and Abdominal Surgery*, p. 486.

PROLONGED SUBNORMAL TEMPERATURE FOLLOWING THE ADMINISTRATION OF ANTIFEBRIN.

BY F. HORTON, M.D.,
OF NEWCASTLE, WYOMING.

THE great length of time during which the temperature remained subnormal in this case, its sudden rise again, and the small number of similar cases in the literature of the subject afford, I think, sufficient excuse for this report:

On October 4, 1891, I was called to see E. L. R., a railroad laborer, twenty-two years of age. I learned that he had been confined to bed for about two weeks.

He presented the symptoms of a well-marked case of typhoid fever: the bowels were very loose; there was tenderness in the right iliac region; rose-colored spots were present; the appearance of the tongue was characteristic, etc. The pulse was 110; the temperature of the mouth was 104°. The patient's surroundings were most unhygienic. He was lying in a one-windowed room, occupied by at least a dozen men as a sleeping-apartment—the beds and room were dirty.

I prescribed two-grain doses of sulphate of quinine, combined with three grains of salol, in capsule—one to be taken every three hours. Bismuth was also given to check the bowels, and I ordered cold sponge-baths, although it was impossible for the baths to be properly given. On this treatment his condition improved, and on the next day his temperature had fallen to 101° in the morning and 102° in the evening.

From this time on until October 13th the case ran a typical course, the temperature ranging from 101° to 102.5°. On the 13th, his temperature ran up to 103°, and the following day to 104°. Being unable to have the baths properly given, I decided to give antifebrin to lower the temperature. I accordingly prescribed antifebrin grs. iv, camphor pulv. gr. ¼, in capsule—a combination I have often used.

He received a capsule at 10 A.M. on the 14th, another at 3 P.M. I saw him at 6 P.M. and found the temperature 97°, the pulse 90. I ordered the antifebrin discontinued. I saw him at 10 A.M. on the 15th, and found the temperature 95°, the pulse 84; I discontinued all treatment, and gave spiritus frumenti ʒj every hour; hot-water bottles were put to the patient's feet under cover, etc. At this time the extremities were cool, but there was no cyanosis. In the evening his condition remained unchanged. On the 16th the morning temperature was 94.6°, the pulse 80. I saw him at 7 P.M., and the temperature had suddenly jumped up to 104°. I then gave the antifebrin in divided doses—*i. e.*, 2 grains every four hours. On the 17th the temperature was 101°, and on the following day normal. From this time on the man made an uninterrupted recovery.

The most remarkable features of the case to me were: the very low temperature, continuing so long after the drug had been withdrawn—nearly forty-eight hours; the suddenness of the rise from 94.6° at 10 A.M. to 104° at 6 P.M.; its sudden decline again, with no apparent evil result. During the time the temperature was below normal the man did not complain of feeling uncomfortable, but maintained that he felt better than he had for some days, although he would feel chilly if the covers were at all removed.

The temperature was taken under the tongue, and at first I doubted the correctness of my thermometer; but, after procuring another and testing my own, I was forced to the conclusion that the instrument was not at fault.

The case was also seen by my friend, Dr. B. B. Kelly, on the morning of the 16th, and the temperature taken by him was found to correspond with my own record. He gave an unfavorable prognosis. I was somewhat alarmed at first when the temperature dropped below normal, fearing intestinal perforation. But, as no further symptoms of this complication occurred, I was inclined to attribute the depression of temperature to the antifebrin alone, given in the weakened condition of the patient.

AN INSTANCE OF CURIOUSLY MIXED EXANTHEM—MOST LIKELY SCARLATINIFORM.

BY J. MADISON TAYLOR, M.D.,
OF PHILADELPHIA.

THIS case, from an old note-book, seems worthy of a hearing.

A robust boy of nine years had, on the morning before I saw him (November 10th), been apparently in perfect health. At mid-day he came home from school complaining of having "caught cold," and feeling a slight soreness of throat. At night the mother—a very intelligent, observing woman—noted a bright rash extending over almost the entire surface of the body. On the 11th this rash was uniformly distributed over the entire surface—a vivid, dusky red. The skin felt hot, stinging, and much roughened by plainly visible papules. These papules were especially prominent upon the forehead, about the ears and the edges of their conchas, and on the neck. The pharynx was irregularly punctate and dusky.

On each of the tonsils was a dirty-yellow ulcer, just about the size and shape of a small watermelon-seed. The tongue was perfectly clean and moist, remaining so throughout the attack. The conjunctivæ were clear and free from injection. The bowels were said to act regularly and sufficiently. The urine for a day or so had been less than normal and of higher color, though voided with increased frequency.

Now, this boy had thrice before had measles, through two attacks of which I had myself guided him. He was a robust little chap of excellent Alsatian ancestry. Scarlatina he had not had. There were symptoms of an acute coryza, with slight cough. The fever was quite active (I do not recall the figures); there was also a full, bounding pulse, but undisturbed breathing. Next day the lad seemed very well, had slept well, called lustily for stouter food, and emphatically proposed going out to play. The fever had lessened markedly, the urine had increased and become of better color. The throat was almost well. Each of the papules already noted had become a tiny vesicle, and the dusky blush, though still uniform, was of a paler tint, with purplish tones. The eyes now seemed injected, and distinct complaint was made of sensitiveness to light.

The next day but one I saw the lad again. The fever had quite gone, the cough was more pronouncedly bronchitic, the eyes were no longer red, the throat was quite healed. Another day passed without my seeing the patient, and on the 16th, lo! the whole surface of the body was now fully desquamating in huge plates. Certain fingers threw off complete glove-like casts. There remained only this and a slight cough, so the family (prudent folk!) announced that my attendance was no longer needed. I saw the boy only once more, some days later, still confined to his room. There was but a patch here and there of half-detached scales on the abdomen, the toes and fingers being immaculately clean. I suspiciously searched the urine for albumin, but found none.

Undoubtedly scarlatina often shows itself as a papular eruption. It rarely exhibits the nasal and conjunctival catarrh so characteristic of measles. But the most curious feature of this case was the punctation of the pharynx—one of the most important premonitory signs of rubeola, the clean tongue, and the very early and complete desquamation.

INFLUENZA FOLLOWED BY PYEMIA.

BY WM. S. BARKER, M.D.,
FORMERLY ASSISTANT PHYSICIAN AT THE ST. LOUIS CITY HOSPITAL, ST. LOUIS, MO.

G. T., nineteen years of age, a laborer, entered the St. Louis City Hospital November 27, 1890. He had had a chill six days before, with pain in his throat and some coryza. With the persistence of the throat pain a general feeling of feverishness had prevailed. When he entered the hospital a huskiness of voice amounting almost to complete aphonia was marked, and slight delirium existed. The temperature was 104°, but was easily reduced by the ordinary antipyretics. There was a slight trace of albumin in the urine.

On laryngoscopic examination intense redness of the posterior wall of the pharynx extending to the adjacent parts of the larynx was detected. There was but little edema of the mucous membranes, and nothing like a diphtheritic exudation could be found in the upper air-passages. The patient complained of general muscular pains and fatigue, quite common in one type of influenza. No visceral lesions could be found. The case seemed to be one of severe influenza, which was somewhat epidemic at the time. The violence of the attack was first concentrated upon the mucous membrane of the pharynx and larynx, but the peculiarity of the case lay in the pyemic involvement of other and distant parts that very soon occurred. The patient's pharynx, mouth, and nasal passages were frequently syringed with hydrogen peroxide, followed by the use of a modified Dobell's solution.

On November 28th, a rather large, flat bleb was first noticed on the palm of the right hand. The contents of this blister seemed at first to be serum, not pronouncedly purulent, though it rapidly became so, and incision two days later evacuated considerable purulent matter. Other similar lesions were soon noticed in various parts, principally on the back and sides of the neck and on the buttocks. These were about the size of a split pea, and usually somewhat enlarged as they became purulent. The severe throat-affection had now moderated and the voice was partially restored. Frequent incisions were made into the lesions described, and when considerable pus could be thus removed the patient's condition seemed slightly improved. The case thus became largely a surgical one. After the incisions general antiseptic measures were employed. It became necessary to make almost daily incisions, as new lesions were constantly making their appearance. An abscess (evidently metastatic) of some depth formed in the left popliteal space. For a week or two in January the patient seemed to hold his own. His condition, however, week by week, became steadily more aggravated. A little later obstinate diarrhea set in—emaciation advanced rapidly, and death took place on January 30th.

The contents of the pustules, examined before death, were characterized by the presence of large numbers of streptococci and staphylococci. The case seemed plainly one of pyemia following influenza.

BISMUTH SUBNITRATE AS A DRESSING FOR THE UMBILICAL CORD.

BY GEORGE A. STUART, M.D.,
OF WAHU, CHINA.

FOR several years I have used bismuth subnitrate as a dressing for the umbilical cord in the newborn. The method of application is as follows: Cut a piece of lint sufficiently large to fold over and prevent the bismuth from being dispersed. Through this a hole is made small enough to fit tightly about the cord and prevent dispersion at that point. The abdomen about the cord is dusted with the bismuth, the cord is passed through the hole in the lint, and the lint pushed well down upon the abdomen. Bismuth enough to completely bury the cord is applied, the lint is folded over smoothly, and the binder applied. The advantages I claim for this mode over all others are the following:

1. Convenience. It has to be applied only once, as

the cord immediately dries up, and does not need to be disturbed until it has dropped off.

2. Cleanliness. There is absolutely no odor, and the addition, at the time of the bath, of a little bismuth to places showing evidences of moisture will keep everything dry and sweet.

3. Safety. Mothers and nurses are not meddling with the dressing, since everything goes on so satisfactorily. There is left no sloughing, discharging stump to corrode the surrounding tissues and bring on hemorrhage or predispose to hernia.

4. The cord drops off sooner than by any other method. For small cords, three days; for large ones, five—rarely exceeding six—constitute the usual time.

5. A better and firmer cicatrix is left than by any other method known to me.

Since I have been using the bismuth dressing I have had no accidents, and 100 per cent. of good results. Much depends upon the manner of dressing, and I have therefore somewhat minutely described its application.

MEDICAL PROGRESS.

External Perineal Urethrotomy.—At a meeting of the Tri-State Medical Association of Mississippi, Arkansas, and Texas, ROGERS presented a report of forty-one cases of external perineal urethrotomy performed on account of the presence of foreign bodies in the bladder and urethra, cystitis, enlarged prostate, stricture of the membranous urethra, and traumatic rupture of the urethra. Death took place in five cases. In two it was due to sepsis from preëxisting gangrene; three cases died from exhaustion. In no instance was death, directly or remotely, attributable to the operation. Five operations were performed without a guide. One case remained unimproved. In each of two cases it was necessary to leave a permanent fistula. In one other a small fistula remained, and this promised to close. When the operation was performed for uncomplicated stricture in the membranous urethra neither rigors nor reactionary fever followed, but in several instances in which these symptoms were present they disappeared immediately after the operation. In the after-treatment rigors and fever occasionally occurred at the first introduction of the sound. The chief reliance in the control of rigor and fever was placed upon morphine administered hypodermatically.

In two cases there was quite troublesome hemorrhage, occurring two and a half and seven days respectively after the operation. The bleeding, however, did not in either case come from the perineal structures, but from the bulbous urethra, where in each case urethrotomy had been performed.

In no case did pelvic cellulitis or septic symptoms follow the operation; but on the contrary the operation relieved the cellulitis when it existed, and in several instances prevented the occurrence of septic symptoms.

The Non-specificity of the Streptococcus of Erysipelas.—At a recent meeting of the Hamburg Society of Physicians, FRAENKEL (*Deutsche medicin. Wochenschr.*, No. 44, 1891) reported that from the pus contained in abscesses that had developed in the course of an attack of erysipelas he had been able to cultivate an organism that corresponded to the streptococcus of erysipelas. He had also observed a case in which the development of facial erysipelas was ascribed to infection from a felon, in the pus of which streptococci were found. In a case of extensive facial erysipelas there was also suppuration of the subcutaneous tissues of the greatly swollen eyelids, and of the inter-muscular and intramuscular tissues of the neck. In the pus and in the edematous fluid streptococci were found, microscopically and by culture. These observations were in harmony with the experimental results already obtained by Fraenkel, from which it appeared that the streptococcus, in accordance with the conditions of infection, at one time occasioned lymphangitis or a phlegmon, at another erysipelas or peritonitis. He had succeeded in inducing erysipelas by injections of streptococci pyogenes into the ears of rabbits; and he had also occasioned suppuration and peritonitis by inoculation of erysipelas-cultures. Nor were the results confined to one species of animal. Thus, some white mice failed to react to intraperitoneal injections of cultures, while others died of peritonitis in twenty-four hours.

"Pental," a New Anesthetic.—MERING, the discoverer of amylene hydrate, has succeeded in producing from the amylene radical an anesthetic, to which, from its containing five carbon-atoms, $(CH_3)_2CCHCH_3$, he has given the name pental. In its volatility and inflammability the product resembles ether; it is used in the same manner as is chloroform. In one hundred instances in which pental was employed the average quantity required in each case was three drams, the anesthesia developing in from three to four minutes. The narcosis is not profound, and is only available for minor surgery. As a rule, operations may be performed before consciousness is completely lost. The advantages of pental consist in the absence of immediate or remote unpleasant effects: it does not cause headache or vomiting; it does not disturb the respiration or the action of the heart, and the stage of anesthesia is not preceded by a stage of excitement even in alcoholic subjects. — *Allg. med. C.-Ztg.* (*Münchener medicin. Wochenschr.*, No. 41, 1891, p. 735.)

The Salts of Strontium in Albuminuria.—At a meeting of the French Society of Therapeutics, DUJARDIN-BEAUMETZ (*Le Progrès Médical*, No. 44, 1891, p. 313) reported that by the employment of strontium lactate he had succeeded in reducing one-half the proportion of albumin in the urine in a number of cases of albuminuria. He ascribed the good results to a favorable influence exerted by the medicament upon the digestion. The drug must be pure; ninety grains may be administered in the course of twenty-four hours.

Ectopia Testis.—POLLAK (*Prager medicin. Wochenschr.*, No. 41, 1891) has reported two cases, one in a lad of thirteen years and the other in an infant of three months, in which temporary displacement of one or both testicles was attended with derangement of micturition, and with pain at remote parts of the body. In both cases restoration of the displaced organs was followed by disappearance of the symptoms.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment. When necessary to elucidate the text, illustrations will be provided without cost to the author.

Address the Editor: GEO. M. GOULD, M.D.,
1004 WALNUT STREET,
PHILADELPHIA.

Subscription Price, Including Postage in North America.

PER ANNUM, IN ADVANCE . . . . . $4.00.
SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,

PHILADELPHIA.

SATURDAY, DECEMBER 19, 1891.

THE WHISKEY TRUST VERSUS THE LIVE STOCK COMMISSIONERS.

THE Live Stock Commissioners of Illinois have made themselves obnoxious to the Whiskey Trust by their efforts to prevent the sale of diseased cattle intended for the beef market in Chicago. Accordingly, the Trust brought suit against the Commissioners, in Peoria, which has ended in a disagreement of the jury. It would be made to appear that the farmers would suffer great loss and that the cattle-trade would be injured if the Commissioners were allowed to condemn beef cattle suffering from the communicable disease known as actinomycosis, or "lump-jaw." This is the same disease that was recently detected in a number of cattle in the Philadelphia stock-yards, and for which the cattle were condemned, while the dealers were bound over to answer at court for selling diseased meat. This anxious solicitude for the farmers would appear inexplicable were it not for the fact that the Whiskey Trust owns great sheds connected with its distilleries, where cattle are fattened on distillery waste for the beef market.

It is a matter of common report that the government inspectors at Montreal not very long ago condemned a considerable number of cattle suffering from actinomycosis, which had been sent to that city from distillery sheds in this country for exportation. It may or it may not be true, but it is reported that this disease is not at all uncommon among cattle in distillery stables. Whether the mode of fattening beef cattle on distillery grains renders them susceptible to this and other diseases we are not prepared to say, but the subject is of sufficient importance to call for a thorough investigation by the Bureau of Animal Industry.

It seems to be a short-sighted policy on the part of the Whiskey Trust and their allies to arraign the Live Stock Commissioners for carrying out measures designed for the protection of the public health, and which, if well performed, tend to relax the restrictions against the sale of Chicago dressed beef in other markets, and thereby broaden the trade.

The willingness of the slaughterers and shippers in Chicago, heretofore publicly announced, to submit to the most rigid and searching inspection and the appointment of State Commissioners to investigate the cattle industry, with the object of eliminating all diseased or suspicious stock, has done much to satisfy the people as to the quality of their cattle and beef. Remove these restrictions, and public confidence is shaken. The enforced sanitary inspection of the great stock-yards and slaughter-houses of Chicago is of more than local importance, and the people of a large section of the country will watch with keenest interest the outcome of the mercenary effort that is being made to baffle the authorities in their attempts to enforce the law directed against a most pernicious practice.

"ETHICS BORN OF UNWORTHY GREED."

AN article with the foregoing title, first appearing in the *Chicago Tribune*, as if from a New York correspondent, has been somewhat extensively copied in other newspapers. It illustrates again the common ruse of charging one's opponent with the identical sin of one's own heart. Controversy is thus befogged, and responsibility shifted. It is a well-known psychological habit of a certain class of minds, when they feel the stings of conscience, to cry, Devil, Devil!

The article in question, with interlarding of much personal vituperation of THE NEWS, repeats with monotonous iteration that THE MEDICAL NEWS, or its editor, in ridiculing the KEELEY cure, writes not with the thought of "the possible good of the

people, but for the mercenary benefit of himself, the motive being a monetary one."

Oh, no! The "mercenary benefit" would follow the purchase from KEELEY, for some $40,000, of a limited territory wherein to practise Keeleyism.

After commending as wise our remark as to the heinousness of advertising a remedy whilst keeping it secret and making a fortune out of the secret, this "correspondent," with characteristic inconsistency, says:

"No profession of gentlemen can turn heaven and earth simply as a charity act, but each and severally they desire to learn the working formula used at Dwight, not for the possible patient or the brother professional, but for the almighty dollar which they believe to be in it for themselves. The repeated attacks, charges of being mercenary, of being inhuman, etc., support the thought that Dr. Keeley will sooner or later seek refuge from this constant persecution by making his secret generally known. To those knowing Dr. Keeley this would be a very fallacious hope. Dr. Keeley will retain his formula into a great futurity before trusting it in the hands of his persecutors."

The advertisement—for such it plainly is (note again how the quack controls, and even fools the newspaper!)—is signed T. B. TANNER, M.D., but the *Medical and Surgical Directory of the United States* contains no such name, neither does the *Medical Register of New York*, nor the *New York City General Directory*.

MESSRS. KEELEY, TANNER & CO. (*unlimited*) may rest assured that the medical profession has not the least desire to know their version of the formula. The essential ingredients of it have been well known since science has studied the history of human delusions and gullibility. The formula, with change of menstruum, was handed down from the medicine men of the most savage tribes of primitive times; APOLLONIUS TYANÆUS, CAGLIOSTRO, HAHNEMANN, and MADAME BLAVATSKY, learned it by heart; all the "seers" and "healers," all the priests and priestesses of modern medical spiritism, faith-cure, astrology, etc. etc.; all advertising physicians; every patent-medicine man, every mountebank of the street-corners, knows all about it. It may be called bichloride of gold, compound oxygen, wizard oil, hoodoo, or *similia similibus*—it is all one!

THE MORALS AND AMENITIES OF MEDICAL CONTROVERSY.

THE *Hahnemannian* for December notifies its contributors and readers that "the editors are responsible for the maintenance of the dignity and courtesy of the journal, and that no discourteous communications will be recognized."

The same issue contains an editorial article wherein, in less than a page, the following are only a portion of the epithets, charges, and comparisons applied to the editor of THE MEDICAL NEWS: "This freak;" "A tallow candle going out with a bad smell;" "Virulence;" "Bigotry;" "Mendacity;" "Blackguardism;" "Mud of bigotry;" "Childish effusion;" "Dr. Jekyll and Mr. Hyde;" "Chameleon;" "Fawning;" "Nightmare;" "Horror;" "Dreams and hints of cut-off salary;" "Squirming;" "Wriggling;" "Crawls;" "Cries Wolf;" "Don Quixote;" "Brave(?) knight;" "Fear of a loss of sustenance;" "Gnashes his teeth;" "Cringingly begs for mercy;" "Sneakingly slurs;" "Not truthful;" "Not honest;" etc.

These gentle courtesies and samples of matchless irony are brought to an end thus: "For the sake of medical journalism, for the sake of an art and science too noble to be dragged in the mud of bigotry, self-interest, mendacity, and blackguardism, may this candle indeed go out, and forever!"

It is worthy of attention that the literary taste displayed by the editor in this exquisite illustration of his "notice" (to readers concerning editorial responsibility for dignity and courtesy) quite overtops the ethics and urbanity there exemplified. One smiles and wonders, for example, how "the little end of the horn" can "go out with a bad smell;" in what manner a "pen" can be "newly-hatched;" if the changes of the "chameleon" and of "Dr. Jekyll" are comparable; how "a bad smell" can be "forgiven," or how it can "rest in peace;" if, really, "Don Quixote" ever cried "Wolf;" how the "highest rank of initial [why *initial?*] virulence and bigotry" can also be "a childish effusion," etc. etc.

For the better understanding of any that may read these lines, and who have not seen the previous issues of THE NEWS in which homeopathic affairs have briefly and rarely been alluded to, it may be well to say that in these columns personalities have had no place. The tenets, theories, and practice of so-called Hahnemannian medicine have been discussed, but without reference to individual practitioners or editors. We have not the faintest spark of personal feeling in the matter.

Such things would not be worth notice did they not among others strikingly illustrate how pauper-

ism of argument and reason, since Euripides at least, flies to passion, objurgation, and personal abuse to hide from itself (again to quote the courteous editor of *The Hahnemannian*) its "trying position" and "sorry plight." One could not wish for an opposing counsel more to his liking. No answer is required, because the plea is quashed and *nolo contendere* ludicrously admitted by hysterics and incoherence. But the cause that is trusted to such advocates must, indeed, be weak and foredoomed.

Ὅταν δὲ δαίμων ἀνδρὶ πορσύνῃ κακά,
Τὸν νοῦν ἔβλαψε πρῶτον.

THE PRIEST-PHYSICIAN OF BAVARIA.

An interesting and instructive monograph has been published by "Sebastien Kneipp, Parish Priest of Wörishofen, Bavaria," on his method of healing disease and preserving health. It would seem that the "water-cure" has had considerable vogue, since the worthy Pfarrer himself describes the visit of Baron Rothschild to the little Bavarian village, travelling in his private car, with cook, secretary, and servants. The Baron took the medicine without flinching, the principal prescription apparently being a daily evening promenade ("to the wondering admiration of the gaping crowd"), bareheaded and barefooted, in a meadow near the railway station. This walking barefoot in the wet grass or snow is an important part of the "system," of which other parts consist in bathing with the clothing not removed, or without drying the body after a bath, the clothing put on the wet body at once, etc. Cold-water baths and mineral-water baths are emphatically condemned. Simple medicinal preparations are used, but it is evident that the chief reliance is placed on the influence of the imagination and the arousing of the will. Evidence of this is seen in the description of the priest's personal appearance:

"A white-haired old man of imposing figure, tall and commanding, and with a powerful face, to which specially dark bushy eyebrows give peculiar character. There is something positively majestic about him; the secret of his power lies in the eyes, looking out at one as they do from the shadow of these prominent brows; his eye looks as though it could penetrate the inmost workings of the soul."

The foregoing description reminds one most forcibly of the descriptions of Father Mollinger.

It is a strange fact that most people, more or less unconsciously, have confidence in what a man says if he but speak with sufficient earnestness, and if a powerful will and commanding personal appearance give added weight to the assertion. All medical miracle-mongers and quack advertisers trade upon this characteristic of human nature.

THE PROPORTION OF ALBUMIN IN URINE.

We call attention to a communication in another column of The Medical News, in which the unfortunate practice of designating the quantity of albumin present in urine by the proportionate bulk precipitated by heat is justly criticised. That this procedure is not only crude and unscientific, but in its results absolutely inaccurate, is amply demonstrated by the data presented in the letter of our correspondent. Of course, the only accurate way of determining the quantity of albumin present in urine is by careful volumetric analysis. This, however, the busy practitioner has neither time nor inclination to carry out; nor is it absolutely necessary for ordinary clinical purposes. Approximative estimates here amply suffice.

Our own method has been to have a mental standard in accordance with the density and thickness of the ring developed by the contact-method of overlaying nitric acid with the urine in which the proportion of albumin is to be determined. In our hands the application of heat to the upper half of the column of clear, acid urine in a test-tube has furnished the best results in the qualitative determination of albuminuria. When heat occasions a slight turbidity indicative of the presence of albumin, and the contact-method fails, we speak of a trace. When, however, we are able to detect a ring by the contact-method, we speak of a thirty-second, or a sixteenth, or an eighth, or a quarter, or a half (and so on) per cent., in accordance with the density and thickness of the ring of coagulated albumin. Only approximative, the method answers admirably for comparative observations, and, while not precise, it possesses the virtue of not being grossly inaccurate and of not being a means of conveying false conceptions, both of which restrictions apply to the designation of the proportion of albumin according to the bulk of the precipitate thrown down by heat. It is at least highly desirable that some uniform method of designation should be adopted.

THE U. S. MEDICAL PRACTITIONERS' PROTECTIVE ALLIANCE.

WE are indebted to the *Maryland Medical Journal* for a just word of warning concerning the medical standing of some of the officers of the U. S. Medical Practitioners' Protective Alliance. The objects of the organization, as set forth in the report, constitution, etc., are so excellent that it is a double pity — supposing true the charges as to the advertising practices, etc., of the officers—that a cause so worthy should not have found the most unexceptionable advocates and leaders. It should not be forgotten, however, that lukewarmness or indifference on the part of physicians to the *stated objects* of the Alliance still remain none the less inexcusable.

SOCIETY PROCEEDINGS.

NEW YORK ACADEMY OF MEDICINE.

SECTION OF GENERAL MEDICINE.

Stated Meeting, November 17, 1891.

DR. BEVERLEY ROBINSON read a paper entitled, "Creasote in the Treatment of Pulmonary Phthisis." Dr. Robinson stated that he considered creasote as the most valuable medicinal agent we have at the present time for treating pulmonary tuberculosis. In nearly all cases marked improvement in the symptoms follows its use. The cough is much diminished in frequency and severity; the expectoration is diminished in quantity and changed in quality; the nutrition is improved; the weight is increased; there is augmented strength and activity; costiveness of the bowels is relieved; night-sweats often disappear. Even in the advanced stages of the disease, when cavities are present, the cough is sometimes ameliorated. The temperature is often favorably influenced by the drug. In several instances the bacilli have entirely disappeared from the sputum, as proven by repeated microscopical examinations. In some cases the expectoration stopped entirely. The physical signs in these cases were also improved. The moist râles disappeared, the breathing became less harsh, and the areas of consolidation smaller. In some cases in which cavities were present at the apices, a marked degree of contraction had followed the use of the drug.

There are few contra-indications for the use of creasote and these few can usually be obviated by its careful administration. Occasionally the stomach does not tolerate it. It may produce headache, or abdominal pain. These unpleasant manifestations may be due to a too rapid increase of the dose, or to a personal idiosyncrasy of the patient. They are to be overcome by diminishing the dose or interrupting its use for awhile. If the drug occasions diarrhea, the same rules apply, or an opiate can be added to each dose. As to the effect of the drug on the kidneys, Dr. Robinson said that usually it is not present in the urine, although it is found there occasionally and in some cases he has recognized a passing albuminuria. When large doses of creasote are given the urine should be examined every few days. In cases of already existing renal trouble he has observed no ill effects from the use of the drug. In regard to hemoptysis, it is claimed that creasote in appreciable doses causes congestion of the bronchial mucous membrane and induces hemoptysis. Dr. Robinson said that nothing in his experience corroborates this view. In regard to the drug itself, the best form to use is that obtained from beech-wood. Much of the so-called creasote that is dispensed in the drug-shops is composed of impure carbolic acid. As for the dose, he begins with small quantities, from one-half to one minim three or four times a day, and later on every two or three hours, if the stomach will tolerate it. Gradually carry it up to from twenty to twenty-five drops in twenty-four hours. One of his patients had taken as much as seventy-two drops daily.

Dr. Robinson said that he had never recognized the advantages of the subcutaneous use of the drug, excepting that larger doses may possibly be administered in that way. Frequent and long inhalations of the drug he regards as extremely useful as an adjunct to its internal administration. The inhalations often improve the condition of the larynx and relieve an obstinate cough. His favorite method of inhalation is by means of the perforated zinc inhaler. For the purpose of inhalation the drug must be combined with alcohol, one dram to the ounce, to prevent irritation.

DR. WILLIAM G. THOMPSON stated that his experience with the use of creasote in pulmonary tuberculosis was so thoroughly in accord with that of Dr. Robinson that he had very little to say on the subject. He has been in the habit of selecting beech-wood creasote and prescribing it in emulsion, or in the form of an enteric pill formulated by Dr. William H. Flint. He has also used Dr. Robinson's inhaler. The drug should be pushed to the limit of physiological toleration. He has never observed any toxic symptoms follow the use of the drug, or any increase in the amount of albumin in the urine in cases in which albuminuria already existed. In conclusion he stated that creasote seemed to him to be the most satisfactory and reliable drug that we have for the treatment of ordinary cases of phthisis, especially in the first and second stages.

DR. WILLIAM H. FLINT stated that his attention was first called to the value of creasote as a therapeutic agent in phthisis by Dr. Robinson's admirable article on the subject, published some years ago in the *American Journal of the Medical Sciences*. He has used it uninterruptedly since that time and regarded it with continually increasing favor. He usually administered the drug in the form of a pill, in which form he thought larger quantities could be borne by the stomach.

DR. WEBBER stated that he has used creasote in the treatment of pulmonary tuberculosis since 1888. In one class of patients in whom well-developed bilateral lesions existed, he had failed to notice any improvement follow the use of the drug, and the patients died. In another class of cases, in which the lesion was unilateral, and in which the sputum showed but few bacilli and no spores, marked improvement in the symptoms was

noted. Dr. Webber said he had never gone beyond ten drops of the drug three times a day.

Dr. James P. Tuttle said that, according to his experience, the stomach does not bear creasote well, especially in advanced cases, where there is always more or less weakness in that direction. He has in a number of cases used the rectum as a medium for the administration of the drug, and within an hour after such an injection the odor of creasote can be detected in the patient's breath, and the patient also can taste it, showing that it is exhaled by the lungs. In making these injections he combines the creasote with sterilized oil. In this way he has carried the dose up to sixty minims in twenty-four hours, using pure beechwood creasote. The benefit of this method of administration is that the stomach is not deranged, and tonics can be given at the same time. In one case he was compelled to discontinue the use of the drug on account of a mitral lesion of the heart. With every administration of the drug the patient manifested great depression, extreme rapidity of the pulse, and a sinking condition amounting almost to fainting.

The Chairman (Dr. Francis Delafield) stated that he has used creasote in cases of pulmonary tuberculosis as a matter of routine practice for a number of years. He thought that perhaps he had not used it with sufficient enthusiasm, and that while the drug unquestionably is of service in some cases, the mortality of the disease is still a very considerable one. The good effects he had got were principally as regards the bronchitis. In many cases he thought the bronchitis was responsible for many of the symptoms, and a chronic bronchitis, with the production of mucus and pus, whether it occurs with tuberculous inflammation of the lungs, or by itself, is very favorably affected by the use of creasote. As regards its administration, he prefers the method of inhalation, keeping it up for a considerable part of the day; or the employment of enemata.

CORRESPONDENCE.

NEW YORK.

The Abuse of Medical Charity—The Office of Coroner—Arsenical Poisoning from Wall-paper.

The well-worn, but not yet threadbare, subject of the abuse of medical charity has quite recently again been brought to our notice by a vigorous article read by Dr. W. H. Bates before the Society of Medical Jurisprudence. He deals with this knotty problem in a wide-awake, practical manner, and draws a faithful pen-picture of the present condition of the medical charities in this city so true to life that no physician familiar with dispensary work can fail to find in it a record of his daily experience. Nor has the author been less painstaking in his search for the causes underlying this miserable state of affairs, as well as for the best remedy. He first calls attention to the fact that more than one-third of the population of this city ask for and obtain medical charity, and that the amount of free work done in the hospitals has increased 90 per cent. in the last decade, while the population has increased less than 50 per cent. He thought that the persons who were the proper objects of medical charity were those whose individual income was less than $500 yearly, for the reason that many such persons do actually pay their physicians. It is a well-known fact that many physicians earn the principal portion of their comfortable income from the people living in the tenement-houses, and that many leading physicians are willing to treat patients for the smallest fees, provided the appointment be arranged so as not to inconvenience the physician. The author then gives a number of instances, which I am sure from my own experience are of daily occurrence, in which people who are abundantly able to pay *something* to the physician visit the dispensaries, and perhaps after awhile, becoming disgusted with the slow progress of their case, go to some private physician and pay well for their treatment. Many dispensary patients lose half a day from their work every time they attend the dispensary; the time saved by being treated by a physician at his office would, in very many instances, enable them without difficulty to pay the physician quite fairly for his services. Investigations on an extended scale have shown that 50 per cent. of the applicants for medical charity are undeserving, and some inquiries have shown the proportion to reach as high as 80 per cent. One fact that is often overlooked in discussing this subject, is the great injury done to the *deserving* poor by overcrowding the dispensaries with those who should seek treatment elsewhere. In this way the time that can be devoted to each patient is reduced, and great haste increases the number of mistakes in diagnosis and diminishes the chances of speedy cure. It is not at all uncommon in large dispensaries for the physicians to devote on an average only one or two minutes to the examination and treatment of each case. Occasionally even the patients themselves stand aghast at the rapidity with which they are ground out of the dispensary mill. I am reminded in this connection of an incident that occurred a few weeks ago in one of our dispensaries. A man who had been to the dispensary several times before, and had always acted in a respectful and orderly manner, seemed disposed to grumble while waiting at the drug-store for his medicine. When asked what was the matter, he replied with an oath that he did not believe that any man living could tell what was the matter with him in eight seconds. It has often been claimed that systematic investigation of the circumstances of those who apply for medical charity would effectually remedy the evil, but experience does not bear out this statement, as the investigation by agents of the Charity Organization Society of suspicious cases applying at one of our dispensaries where thirty thousand new patients are treated annually, only lowered the abuse of medical charity 10 per cent., and in another dispensary, as a result of five years of work, the reduction was 25 per cent. This plan has proved impracticable on a large scale, partly on account of the great number of agents required to do the work properly, and partly because the patients, after being refused at one dispensary, learn how so to modify their story as to be more successful when they apply at another dispensary. The remedy that Dr. Bates suggests is, that every patient who applies to a dispensary shall *sign* a written statement, giving his address, total

income of the family, number in the family, and other similar details, and that it be made a misdemeanor, according to the laws of the State, for any person to make a wilful misstatement in filling out such an application. There are, of course, many objections that might be offered to this plan, most of which, however, are theoretical; and the strong point in its favor is that it has already been successfully employed by the Charity Organization Society in preventing the abuse of general charity.

Another matter that often elicits much unfavorable criticism from our physicians concerns the office of coroner. Most of us will admit that the system is not what it should be, or else that those in the office do not carry on its functions properly. How to improve this order of things was the subject of discussion at a recent meeting of the Section of Public Health at the Academy of Medicine. The discussion was opened by a paper by Dr. Stephen Smith, in which he stated that the functions of the coronor were chiefly medical and judicial, and that he thought it would be better to make the medical inquiry a part of the work of the Health Department, where the examination by medical experts would often render judicial inquiry unnecessary. The registrar of vital statistics of the Board of Health would have charge of the verification of deaths, and would discriminate between the death certificates that were entirely satisfactory and those that were not quite satisfactory. The latter class would then be personally investigated by assistants, and if there were any evidences of crime the attorney of the Board of Health, or one from the District Attorney's office, could take testimony and compel the appearance of witnesses before a court appointed to take the first proceedings in the case. Meanwhile the medical officer would make a thorough examination in a suitable place set apart for that purpose. As we have through the agency of the State Board of Health a most complete system for the verification of deaths, extending to the most remote places, and as the health officer in the country districts is generally far more competent than the man elected to act as coroner for the county, it follows that but few changes would be necessary in adopting this modified system. Mr. Clark Bell, after an exhaustive study of the subject, had come to the conclusion that no constitutional amendment would be necessary, as the needful changes could be secured by simple legislation.

In the discussion that followed the reading of this paper, Dr. Philip Donlin defended the coroner's office, and gave a sketch of the extent and character of its daily work. He suggested that by having more coroner's physicians and better accommodations at the morgue for examinations, the work of the office could be much improved, and many pathological investigations carried on that would be of lasting benefit to medical science.

Mr. Ellinger, who was formerly coroner for a period of six years, also favored having more coroner's physicians, and thought it would be an improvement to have the term of service of the coroner extended to the same length as that of a police magistrate.

After the discussion, it was recommended that the Academy of Medicine appoint a committee to confer with the medical and medico-legal societies in the city concerning needed reforms in the coroner's office.

A year has passed since the Academy took possession of its new and handsome building, and at the first anniversary meeting a popular address was delivered by Prof. Charles F. Chandler on "Arsenic in Common Life." In this address he devoted himself to the task of exploding the widely prevalent idea, both in lay and professional circles, concerning the dangers from arsenic in wall-paper. He said that he had himself believed in it without ever making any special investigation, up to the time when his duties in connection with the Board of Health required him to make it a special study. He then found that the idea had been started by a botanist, and that it was based on the most flimsy reasoning. He next made some experiments in the laboratory by passing air over sheets of paper—some moist and others dry—coated with Paris-green. Not a trace of arsenic was found in this air. Much of his address was devoted to a narration of cases that had occurred in Boston during a time when the people in that city were much excited over the supposed dangers from arsenical wall-paper. The most important case was that of an ex-mayor of Boston, who had been supposed to be suffering for a long time from this form of poisoning, but the post-mortem examination showed that he had died from cancer of the stomach. The wall-paper that had been supposed to be the source of the poisoning in his case had not been changed from 1817 to 1891. While it is quite possible that in the old-fashioned wall-paper, that the arsenical dyes were loosely attached to the paper, the arsenic might become detached and diffused through the air, the amount would ordinarily be quite insignificant; and in the wall-papers made in the last fifteen years no arsenical pigments have been used, and the presence of arsenic in these papers, as determined by delicate chemical tests, is due entirely to accidental impurities. Some of the papers that were thought to have caused poisoning had been on the walls for thirty or forty years. Supposing, for the sake of argument, that there were sixty square yards of paper in a room, each yard containing one grain of arsenic—the amount found in several of the cases quoted—and that during a period of thirty years *all* the arsenic had left the wall paper and had entered the human system without any being lost, this would be at the rate of one grain in six months, or only $\frac{1}{180}$ of a grain in each twenty-four hours. Many distinguished scientists have independently investigated this subject of poisoning from arsenical wall-paper, and they all agree in saying that there is "nothing in it."

REMARKS ON PROFESSOR GOODELL'S PAPER IN "THE MEDICAL NEWS" OF DECEMBER 5TH.

To the Editor of THE MEDICAL NEWS,

SIR: The current literature of abdominal and pelvic surgery is burdened, even cursed, with productions from those who have little natural surgical aptitude, no originality, less genius and still less wisdom born of experience. The average practitioner is forced to winnow the wheat from the chaff in such an article. He considers the source from which it emanates, and is unlikely to use a method of practice which he sees is based on theory, is dangerous, or has little or no practical utility. The

effect on the general practitioner and amateur operator is very different when he reads a production from the pen of the distinguished teacher and operator, Prof. William Goodell.

With these thoughts in mind I offer a few remarks concerning his article. I indorse much contained in this valuable paper. As an American I am deeply interested in the success of American operators. Professor Goodell makes the statement that many, perhaps the majority of American gynecologists, following the lead of Péan and Richelot, have adopted the procedure of securing the broad ligaments with forceps, and adds that there is hardly one, not excluding himself, who has not invented a special form of clamp. To me it is a matter of indifference how many operators have invented forceps. It is, however, a matter of great importance if any forceps has been invented and a principle of operating has been perfected by which the broad ligaments are first narrowed to a round mass and brought well down into the vagina so that the peritoneal lining of the pelvis can be closed above by perfect sero-serous approximation. The forceps that I use has a beak so constructed as to assist in bringing the peritoneum together above their grasp, thus securing absolute extra-peritoneal fixation of the stumps of the ligaments.[1]

Dr. Rufus B. Hall, of Cincinnati, who recently used the same forceps, writes me: "The principle of puckering up the ligaments is correct."

Of course, when ovaries and tubes are removed I prefer the silk ligature left long, but even then the peritoneal cavity must be perfectly closed (except where a small drainage-tube is inserted to remain twenty-four hours only).

Professor Goodell has less objection to the progressive silk ligature than to the forceps. In abdominal or vaginal hysterectomy I am an advocate of the silk ligature, but always aim to unite the serous membrane, so that there will be no raw surface left in the peritoneal cavity. After having seen Prof. Olshausen and other distinguished German operators use catgut, I am convinced that while experts like Olshausen and Goodell can secure faultless catgut and have ideal results with it, the average operator would have more deaths from hemorrhage and septicemia than recoveries, and would have better results with forceps constructed on proper principles, or with the silk ligature, which in itself affords capillary drainage from the tissue within its grasp. If daily subjected to tension it nearly always comes away by the end of the second week.

When serous membranes are nicely adjusted I have repeatedly found firm union in forty-eight hours, so that vaginal irrigation gave the patient relief by cleansing the wound now absolutely shut off from the peritoneal cavity and within reach of antiseptics.

I have no fears whatever of the antiseptic wash breaking up the adhesions of a serous membrane. By first puckering the broad ligament to a round mass and accurately approximating the serous surfaces I have recently had a series of twenty-one consecutive vaginal hysterectomies without a death. I am an uncompromising advocate of vaginal hysterectomy, believing it to be the best palliative treatment for cancer of the uterus, if nothing more, and for this reason I want to see all who undertake this operation enjoy the largest possible measure of success.

THE RAGE FOR NEW DRUGS.

To the Editor of THE MEDICAL NEWS,

SIR: There appeared in THE MEDICAL NEWS of November 7th an able and vigorous editorial article based upon the report of a case of poisoning by "antikamnia," calling attention to the dangers of prescribing pharmaceutical products the composition of which is unknown, and roundly denouncing manufacturers for foisting such goods upon the profession.

But the substance named is only one of hundreds of so-called new remedies, the manufacturers from the sale of which, with the aid of the medical profession, are waxing rich. These preparations are effusively lauded to physicians by their introducers, and thrust upon our notice in every conceivable way—and it is rarely the case that the extravagant and often ridiculous claims made for them are not fortified by apparently reputable medical authority. This appears to be, in fact, a *sine qua non* to "success" in the new venture.

For the real cause of this evil, however, it seems to me that we need not go so far from home as to the chemist or to the pharmacologist. It is but incidental to a far greater evil that pervades the medical profession and for which physicians themselves are responsible. I refer to the craze for therapeutic novelties—the mad rush for new remedies that has been observable for the last few years.

It is a deplorable fact that manufacturers are not more eager to sell their new, fancifully named products than physicians are to prescribe them. Scientific conservatism has been flung to the winds and a spirit of reckless experimentation seems to have taken possession of the profession. The pharmacologists and chemists are merely profiting by the occasion. The credulity and the recklessness of physicians mean dollars and cents to the manufacturers. As between the latter and the physicians who prescribe their nostrums and by whose encouragement and patronage they thrive, the manufacturers are the less culpable.

It is indeed "time to speak plainly and to act courageously." It is time for such leaders in true medical progress as THE NEWS to call a halt upon the present reckless, indiscriminate, and dangerous practice of prescribing new and untried pharmaceutical products. It is not because of this tendency, but in spite of it, that the real advance in modern therapeutics has been made. No "new remedy" should find a place in the armamentarium of the private practitioner until its physiological and therapeutic actions have been carefully studied and its value proved by observers of unquestioned competency.

MACCLENNY, FLA.

MAXIMUM PERCENTAGE OF ALBUMIN IN URINE.

To the Editor of THE MEDICAL NEWS,

SIR: In THE MEDICAL NEWS of December 5th Dr. C. S. Stewart, in a clinical report on the action of

nitro-glycerin, says that he found in his third case "fully 50 per cent. of albumin in the urine." This is not the first time that I have met with such an assertion. Many cases have been related to me in which the physicians stated that they had found from 25 to 75 per cent. of albumin. It would be interesting to know the method by which such a percentage is obtained.

Let it be supposed that 1200 c.c. of urine are on an average excreted per day; that quantity of urine would, if it contained "fully 50 per cent. of albumin," carry with it more than 600 grams of albumin. The albumin found in the urine is, in the majority of cases, serum-albumin, the escape of which from the blood into the urine is due either to a histological change in the epithelium of the kidney, or to abnormal blood-pressure.

Human blood contains about 8 per cent. of albumin, of which about 3.4 per cent. is paraglobulin, and about 4.6 per cent. serum albumin. The amount of blood in the human body is about one-thirteenth of the body-weight. Thus it may be easily calculated that, according to the foregoing assertions, the whole amount of albumin in the blood is less than the amount excreted in the urine in one day. The maximum found by Vogel (Neubauer und Vogel, *Harnanalyse*, 9th ed.) was 28.3 grams per day, or 2.35 per cent. G. M.

WORMS IN THE AUDITORY MEATUS.

To the Editor of THE MEDICAL NEWS,

SIR: On June 13, 1886, G. B., a boy, twelve years of age, was brought to my office by a gentleman, who stated that he had extracted four worms from the boy's ear. Upon examination of the ear, I found catarrh of long standing, with purulent discharge and perforation of the drum. I also readily succeeded in extracting eight more worms, making twelve in all that were dislodged from the meatus that day. They were doubtless of the variety known as the fly-worm. The green fly, being attracted by the aural discharge, deposited its ova, from which developed the grubs.

GLASGOW, DEL.

REVIEWS.

A PRACTICAL TREATISE ON THE DISEASES OF WOMEN. By T. GAILLARD THOMAS, M.D., LL.D. Sixth edition, enlarged and thoroughly revised by PAUL F. MUNDÉ, M.D. Philadelphia: Lea Brothers & Co., 1891.

THE character of the previous editions through which this book has passed insure it in its new form a hearty reception at the hands of the medical profession. The sound conservatism of the work is in no way impaired by the progressive teaching evinced in the present revision. A text-book upon the diseases of women, to be of use to students and general practioners, can meet the varied requirements only by presenting the subject in the light of knowledge possessed by an author of exceptional experience. Such an author must know what to avoid as well as what to include in his subject. Extreme ideas, because alluring to the writer, should find no place in such a text-book. If the extensive experience of the author in this instance has already entitled him to his present position as a teacher, the revision of his work by one who offers "an active experience of twenty-five years as a writer and practitioner in the same specialty" cannot fail to increase the existing confidence of the profession in such a work.

The fact, however, of the reviser, as the result of his own experience, possessing mature ideas upon those subjects in which he may hold opinions at variance with those of the author, makes it difficult for him to so far modify his own views as to offer to the reader the impression of a conclusive opinion. This difficulty is increased by the necessity of the reviser stating in brackets his own views when differing opinions exist. This appears like an interruption to the text, although the reader finds the advantage of being able, in this way, to compare the views of two writers.

In regard to the arrangement of the book we think that it would have been more scientific to have described the inflammatory and positional disorders of the uterus in juxtaposition to the neoplasms, without separating these topics by introducing the chapters on para-uterine cellulitis, pelvic peritonitis, pelvic abscess, and pelvic hematocele.

The author's views upon the significance of laceration of the cervix serve as a wholesome correction to the enthusiasm of those that at present decry trachelorrhaphy, as well as the other procedures included under the head of minor operations.

The chapter on electricity, added since the last edition, is in every way to be commended. The clearness of the descriptions and the conciseness of statement render the contents of this chapter invaluable to the student, while the conclusions of the writer, as the result of a large experience, appeal to the more experienced practitioner.

We regret that the chapter on pelvic hematocele has not dealt more fully with the question of causation, relative to ectopic gestation. In view of the recent advance in this subject the writer's views would have been interesting not only to the specialist, but of great value to the student. The critical reader will find the chapter on diseases of the Fallopian tubes well up to the standard of our knowledge at the present time, especially on the subject of drainage. The use of the clamp and cautery, although mentioned in the text, is not insisted upon; and while the chapter contains all that is essential to a thorough knowledge of the technique, simplicity of method—so universally adopted now among surgeons—is clearly advocated. The profession will receive with gratification the wholesome warning "against the indiscriminate, hasty, and routine performance" of laparotomy in the treatment of diseased appendages.

The teaching in this work is preëminently conservative and at the same time progressive. Its value to the profession lies in the fair discussion of opposite opinions and the absolute avoidance of even an appearance of dogmatism.

ESSENTIALS OF PHYSIOLOGY, ARRANGED IN THE FORM OF QUESTIONS AND ANSWERS; PREPARED ESPECIALLY FOR STUDENTS OF MEDICINE. By H. A. HARE, B.Sc., M.D., etc. Third edition. Philadelphia: W. B. Saunders, 1891.

ACCORDING to the notice on the title-page of this third edition, it has been "thoroughly revised," and in his preface the author assures us that he earnestly desires

that the depth and scope of medical education may be increased. But the volume contains much that disproves the truth of the notice and the sincerity of the assurance. There is also everywhere an incomprehensible and slovenly use or abuse of the English language. We can cite only a few of the many illustrations that have struck the attention in turning the pages. Take the first sentence: *Physiology is the study of vital phenomena, which are always present in living things be they animal or vegetable.* One can only ask, Where but in living things could vital phenomena be present? Why the word *always?* and where except in animal or vegetable things are vital phenomena seen?

If it be worth mention, why not correctly state the number of chemical elements?

What nonsense to say that "the saline taste of the blood is dependent upon the salts contained in it."

The amazing answer to the question, *What are the physical forces of the circulation?* is too long to quote.

What would a physiologist say to the statement that "the blood descending in the femoral artery shoves the blood up the corresponding vein?"

The optic nerve is said "to appreciate light," "yet light can never be said to produce activity of the nervous protoplasm by contact."

As to the function of the choroid coat, not a word is said about its true function, or its vessels, but much about its "black pigmented cells"—which do not exist. The pigment layer belongs to the retina.

"Each portion of the retina" is said "to receive different colored rays. The peripheral portion sees the red rays, etc."

Diplopia is said to be "due to the fact that each eye receives the impulse at a different time from the other."

Hypermetropia is defined as a condition "in which objects are focussed behind the retina," and the lens of the myopic eye is said to be "too convex, while in the hypermetropic eye it is not convex enough."

The function of the Eustachian tube is said to be "to equalize the pressure within and without."

The plates from Arnold's *Icones Nervorum Capitis* are most excellent.

The Surgical Treatment of Wounds and of Obstruction of the Intestines. By Edward Martin, M.D., Instructor of Operative Surgery, University of Pennsylvania, Surgeon to the Howard Hospital, Assistant Surgeon to the University Hospital, and H. A. Hare, M.D., Professor of Therapeutics, Jefferson Medical College; Attending Physician to St. Agnes Hospital. 8vo., pp. 169. Philadelphia: W. B. Saunders, 1891.

This essay was awarded the premium of the Fisk Fund by its trustees at the annual meeting of the Rhode Island Medical Society, held at Providence, June 12, 1890, and this distinction should be a sufficient guarantee of merit.

The subject of intestinal obstruction is dealt with in twelve chapters; two additional chapters are devoted to wounds of the intestines, the whole being rounded off by a very complete collection of 130 cases of celiotomy for gunshot wounds of the abdominal cavity, which are very instructively analyzed in the final summary.

The various subjects embraced under the vast and comprehensive title of intestinal obstruction are generally treated with judicious discretion and well-balanced judgment. If there is a distinctive feature that is everywhere recognizable in this essay, it is its conservatism. In all conflicting questions, in which the contending parties are liable to run to extremes, we find the authors invariably inclining toward the safe old percept *in medio tutissimus*, etc., the verdict of the authors being generally grounded on sound reason. This tendency is well illustrated in the chapter on peritonitis, in which the authors are neither exclusive advocates of purgation *à la* Tait or of opium *à la* Alonzo Clark. There are cases for opium and cases for salts, and they tell us which are the cases respectively. In the diagnosis and treatment of obstruction, the relative merits of watery enemata and gaseous insufflation are considered. Here, in opposition to distinguished authority, the authors believe in the superiority of water as an injecting medium, especially for therapeutic purposes, and while many will not be prepared to admit the full extent of their contention, none will deny, after reading the argument, that there is more good service in water in the treatment of obstruction than some recent writers would teach us to believe. In connection with rectal injection, the important subjects of heat-preservation during the injection of the large enteroclysmata required in intestinal obstruction, as well as during operation, and the effects of intra-abdominal pressure produced by forced enemata, are studied in a clear and conclusive manner. This part of the work, which is already familiar to the readers of Philadelphia medical literature, is indeed most original and commendable, and is distinctly illustrative of the value of laboratory research to the clinician.

The spirit of conservatism is again manifested in the more strictly surgical sections. For instance, simple enterostomy as distinguished from the more formidable abdominal section, receives here an amount of attention and commendation that we would scarcely find in the writings of the more aggressive class of operators who barely tolerate it and show a decided disposition to relegate it to the past rather than refer to it as an operation of the future. In justice to Senn and his followers, we believe that a more extended reference to the relative merits of enterostomy and lateral anastomosis should have been made, since modern "aided" anastomosis has as decided a claim to be considered an emergency operation as enterostomy—though clinical data upon which the comparison could be instituted are still wanting and are only available by experimentation.

Much more could be said in the matter of technica details in intestinal operations than is contained in this work, though the essential operations are sufficiently described. It is probable that in a second edition the authors will lay more stress on the positive superiority of the plate over the ring as an aid to anostomosis, and will also insist more emphatically on the greater dangers of circular enterorrhaphy as compared to lateral anastomosis in enterectomy.

The hemoglobin test, suggested by the authors, in establishing the frequently perplexing differential diagnosis between shock and hemorrhage in abdominal injuries, may prove helpful to hospital and city surgeons. The test is a fairly accurate guide to the volume of blood

lost, and with the aid of the hemoglobinometer "can be made in two minutes."

The printer's errors are few, but of these one deserves attention: in page 120, the word "enterorrhaphy" appears instead of "enterostomy," an oversight that may easily lead to confusion.

EVIDENCES OF THE COMMUNICABILITY OF CONSUMPTION. By G. A. HERON, M.D. (Glasgow), Fellow of the Royal College of Physicians of London; Physician to the City of London Hospital for Diseases of the Chest. 8vo., pp. 167. London and New York: Longmans, Green & Co. Philadelphia: P. Blakiston, Son & Co., 1890.

DR. HERON believes that the bacillus tuberculosis of Koch is the sole and efficient cause of tuberculosis; that the disease is propagated by infection chiefly through the sputum of the phthisical, but also through infected meat and milk, and in other ways. He urges that the original experiments of Koch, since abundantly confirmed; the elaborate investigations of Cornet, especially those into the fatality of tuberculosis among the nursing conventual orders of Prussia—which are here reproduced—and the accumulating clinical evidences of transmission of consumption, much of which he cites in summary in an appendix, all combine to leave no doubt as to the correctness of the position taken. He therefore advocates the utmost care to prevent transmission by sputum and by infection of rooms, clothing, and so forth, and the legal slaughter and extinction of all tuberculous animals. The alleged immunity of Jews from tuberculosis is attributed in part to their sanitary laws, such as the annual scrupulous and exhaustive house-cleaning of Passover, and more especially the rabbinic ordinances as to "kosher" meat. The increase of tuberculosis among Russian Jews in London in the last two years he attributes in part to the brutal persecutions by which Alexander the Cruel has disgraced the Christian civilization of the nineteenth century, and in part to the fact that the refugees, having been robbed of their all by Russian officials, are compelled to herd in those districts of London where poverty and vice have long been breeding disease, and as a consequence have been exposed to the infection from which their religion and its laws of cleanliness and sobriety had hitherto protected them. In this he finds an additional confirmation of the view that phthisis originates by infection, and only by infection. While the reviewer does not subscribe to the extreme view of the author, he is at one with the latter in the practical lessons of precaution taught. The work is well done. It has a good index, and to English-reading physicians will be extremely useful for reference.

TRANSACTIONS OF THE TEXAS STATE MEDICAL ASSOCIATION. Twenty-third Annual Session, held at Waco, Texas, April 28, 29, 30, and May 1, 1891. Edited by HAMILTON A. WEST, M.D., Galveston, Texas.

THIS volume of the transactions of the Texas State Medical Association contains a series of papers of considerable interest and of practical importance. It is impossible to enumerate all the names of its contributors, or even to detail the important features of its most noteworthy articles; suffice it to say that the book is a credit to the Association and to its individual contributors, and will amply repay the reader for the time spent in its perusal.

The following is a list of a few of the contributions, together with the names of the respective authors:

"The Responsibility of the Medical Profession in the Use of Alcoholic Stimulants," by W. A. Morris, M.D.; "Points of Interest in the Clinical Examination of the Urine," by J. H. Wysong, M.D.; "Some Practical Observations on the Management of Albuminuria of Pregnancy," by J. F. Y. Paine, M.D.; "Wiring of the Vertebræ as a Means of Immobilization in Fractures and Pott's Disease," by B. E. Hadra, M.D., etc.

STORIES OF A COUNTRY DOCTOR. By WILLIS P. KING, M.D. With illustrations by T. A. FITZGERALD. Philadelphia: Hummel & Parmelee, 1891.

IN the nearly four hundred pages of which this volume is made up, the trials, incidents, experiences and observations that enter into the life of a country practitioner of medicine are portrayed with a certain dash of humor. The text is not only included between pages of advertisements, but in one or two places is interleaved with them. The book is otherwise neatly printed and bound. It may meet the wants of a certain class of readers.

MASSAGE: A PRIMER FOR NURSES. By SARAH E. POST, M.D., Lectures before the Training School for Nurses connected with the Bellevue Hospital, Mt. Sinai Hospital, and St. Luke's Hospital, New York, also with the Memorial Hospital, Orange, N. J. 12mo., pp. 47. New York: Nightingale Publishing Co., 1890.

THIS little book is to be highly commended for its lucidity and brevity. It does not attempt to teach the practice of medicine nor to throw upon the operator the responsibility for deciding when and how massage is to be applied for the relief or cure of abnormal conditions. It gives, however, clear, concise, and reliable directions as to the manner in which the instructions of the physician upon these points are to be carried out.

A COMPEND OF HUMAN PHYSIOLOGY: ESPECIALLY ADAPTED FOR THE USE OF MEDICAL STUDENTS. By ALBERT P. BRUBAKER, A.M., M.D., etc. Sixth edition, revised and improved, with new illustrations, etc. Philadelphia: P. Blakiston, Son & Co., 1891.

PROFESSOR BRUBAKER meets the continued demand for his manual with revision, enlargement and new illustrations. Barring the objection to be urged against all such works, no criticism of this capital little book can be offered.

CORRECTION.

In "A HINT TO THE LITERARY MEN OF THE PROFESSION," in THE MEDICAL NEWS of December 12, on page 682, the place of publication of the *Journal de Physiologie* should have been printed Paris, and not Berlin; and that of the *Archiv für klinische Chirurgie* should have been printed Berlin, and not Leipzig.

HIP-JOINT DISEASE AND SOME NEW LATERAL-TRACTION SPLINTS FOR ITS TREATMENT.

BY A. M. PHELPS, M.D.,

PROFESSOR OF ORTHOPEDIC SURGERY IN THE UNIVERSITY OF NEW YORK AND IN THE NEW YORK POST-GRADUATE SCHOOL AND HOSPITAL; PROFESSOR OF SURGERY IN THE UNIVERSITY OF VERMONT.

THE profession of America is somewhat divided upon the subject of the treatment of hip-joint disease, and for the purpose of adding, if possible, a few facts to our knowledge of the subject I present this paper.

1. I will state that I believe that muscular spasm is always present in morbus coxarius.

2. That muscular spasm produces great intra-articular pressure.

3. That the articular pressure produced by the muscular spasm is a very serious element in bringing about the destructive changes that are so frequently and so generally seen in joints untreated or badly managed.

4. I also believe that, so far as possible, *absolute immobilization of an inflamed joint until perfectly cured should be insisted upon, and that voluntary or passive motion should be most emphatically prohibited.*

If these ideas are correct, clearly one of the most important steps to be taken in the management of hip disease is to control the spasm of the powerful muscles operating upon the joint by means of extension and fixation applied so as to antagonize the contracting muscles, and put the joint at rest. The great adductor muscles, as is well known, pass obliquely across the body from the pelvis to the femur. The great glutei muscles, the abductors of the thigh, also pass obliquely from the pelvis to the great trochanter. The rotators take the same direction. These muscles are affected by spasm in hip-joint disease, and they make traction in the line of the neck and shaft of the femur. To control the spasm of these muscles and to relieve intra-articular pressure, lateral traction must be made in a line corresponding to the axis of the neck. The flexor muscles of the thigh should be controlled by longitudinal traction, and the entire joint fixed. This will be explained later.

How long should the joint be fixed? Until it is perfectly cured. The fear of ankylosis has tended to deter the profession from adopting prolonged fixation of joints inflamed. Hence the devising of the long traction-splint, which admits of free motion of the joint. It was born of the fear of ankylosis on the one hand and the desire to give the patient exercise on the other. It is still extensively used by eminent members of the profession, notwithstanding that those who use it, as well as many of us that have used it, know that the vast majority of the cases so treated either result in ankylosis, shortening, or almost without exception, angular deformity. It is not my purpose to denounce the brilliant advance in treatment that the advent of the long traction-splint marked over the older methods in vogue at the time of its invention, but only to call attention to its defects, and, if possible, to point the way to other methods that I hope may overcome the errors of the past.

The belief that motion, by increasing the circulation, stimulates the inflamed joint to healthy action, and also the fear of ankylosis, have led eminent men to employ passive motion throughout the course of the disease.

To determine the question whether prolonged fixation of the healthy joint would result in ankylosis, with Prof. W. Gilman Thompson I performed a series of experiments in the Loomis Laboratory upon dogs. Four dogs were selected, and their legs immobilized; the joints were examined at the end of the sixth week and at the end of three and five months. At the end of six weeks, one of the dogs, the leg of which had been placed in a cramped position, so as to produce great intra-articular pressure, was killed. In this case, upon opening the joint, a dark-red spot was found upon the head of the bone that corresponded to a similar spot in the acetabulum, marking the point of contact between the head and the socket. There was also congestion of the entire head of the bone and of the ligamentum teres closely resembling the congestive stage of inflammation. The synovial membrane was normal; a section was made of the head of the femur which divided it into halves. Beneath the articular cartilage, and extending a considerable depth into the head of the bone, the cancellated structure was deeply congested and filled with coagulated blood. The other dogs were killed at the end of three and five months, and the joints were found to be normal.

The conclusions at which we arrived from these experiments were:

1. That a normal joint will not become ankylosed by simply immobilizing it for five months.

2. That motion is not necessary to preserve the normal histological character of a joint.

3. That when a healthy joint becomes ankylosed, or its normal histological character changed, it is not from prolonged rest, but from pathological causes.

4. That immobilizing a joint in such a manner as to produce and continue intra-articular pressure will result in destruction of the head of the bone and of the socket against which it presses, as is evidenced by the specimen secured in one of the cases.

5. That atrophy of the muscles of the limb will follow prolonged immobilization of the joint.

If these experiments prove that prolonged fixation will not produce ankylosis of a normal joint, that motion is not necessary for the preservation of its normal function, then the causes of ankylosis must depend upon the pathological conditions, and not upon prolonged fixation.

In the treatment of inflamed joints it is claimed that motion prevents ankylosis. This must be a mistake, because the statistics of joints so treated show that ankylosis and deformity to a greater or less extent are by far the most frequent results.

The statistics published by Shaffer and Lovett in the *New York Medical Journal* show that, in 39 cases finally reported upon in the series, there was

Ankylosis in	19
Slight motion in	6
	25
Motion of from 10 degrees to 44 degrees in	7
Motion to a right angle in	3
Motion free in	3

The three with free motion were treated during the first stage of the disease. Two were under three years old. There were only two cases without shortening.

The splint used was the long traction-splint, which admits of free motion at the hip-joint. To test this question still further, I sent a patient with knee-joint disease, whom I had nearly cured, to a distinguished masseur for treatment by massage. I had perfectly fixed her joint for one year. The apparatus was removed, and she had motion to about 35 degrees; there was no pain, and she could walk with ease. She was attended daily by the masseur. Her leg was flexed and systematically moved and rubbed. After six months I found almost complete ankylosis. A recent examination showed fibrous ankylosis and only a slight degree of motion.

The so-called "ossified man" paid a masseur to move his inflamed joints during two years of his early joint-trouble. The result was perfect bony ankylosis of all the joints that were inflamed.

The fakirs of India, after twenty years of penance, holding their limbs in one position, quickly regain the normal use of their joints after their religious frenzy has passed. (Thomas.)

I have several cases of children suffering from joint-disease that have been immobilized in a portable bed ten, twelve, and eighteen months, the joints of the lower extremities being kept perfectly quiet during the time. Recent examinations demonstrated that ankylosis had not taken place in the normal joints, while the inflamed joints are freely movable.

FIG. 1.

Fig. 1 is taken from the photograph of a child suffering from hip-joint disease that had been immobilized in a plaster-of-Paris portable bed for sixteen months. The case was perfectly cured, notwithstanding that aspiration of a quantity of pus from the joint was necessary.

I desire to place these cases on record, to stand by the side of the reported cases of ankylosis, supposed to be due to prolonged rest of joint.

In the treatment of wounds, inflamed organs and

tissues, rest is one of the most important surgical laws. The surgeon protects the wound from friction by means of proper dressings, and the ophthalmologist puts the inflamed iris at rest by the use of atropine. Since rest is a surgical law in the treatment of inflamed tissues in other parts of the body, and motion is not necessary for the normal preservation of a joint (nor can it in any way prevent ankylsi s of an inflamed joint) I believe that we should not make an inflamed joint an exception to a well-established surgical law.

The question of ankylosis is determined by the severity, the character, and the duration of the inflammation, the presence of intra-articular pressure, the subsequent cicatricial contraction of soft parts around the joints, the tissues involved, and the amount of destruction of bone and cartilage. Motion of an inflamed joint only interferes with repair, and more certainly hastens the case on to ankylosis and deformity. To prevent this calamity, when possible, absolute rest and the relief of intra-articular pressure should constitute the plan of treatment. Inflamed joints treated upon this plan furnish by far the fewest cases of ankylosis, limited motion, and deformity.

Let us now consider mechanical treatment. During the period of deformity and the acute and primary stage of the disease, nearly all cases of hip-joint disease are better treated in bed than elsewhere—for the reason that in bed the joints can be more perfectly immobilized. Here we can apply extension uninterruptedly, and at the same time fix the joint by holding the limb and body in a fixed position. No one would for a moment think of adjusting a walking splint to the fractured limb of a child, or even allow the child to go about on crutches with a splint. Still this practice is almost universally resorted to in hip-disease—a disease much more menacing to life and limb than a simple fracture of the femur.

At the Post-Graduate School and Hospital we usually put our patients to bed for a time varying from three weeks to three or four months, until the deformity is entirely overcome, and the more active stage of the disease somewhat ameliorated.

Fig. 2, from a photograph, shows a patient with the bed-dressings adjusted. A long splint is put on the well limb, and the leg and body to the axilla are enveloped in a plaster-of-Paris bandage. Adhesive plasters are applied to the limb; extension and traction are made in the line of the deformity and at right angles to that line—from six to ten pounds of longitudinal traction, from one to three pounds of lateral traction being employed, for the purpose of overcoming the spasm of the adductor and abductor muscles.

FIG. 2.

Children under three and a half years of age are treated with a plaster-of-Paris portable bed. Others are put upon crutches, with a high shoe and a lateral-traction fixation splint adjusted.

The bed-treatment, as described, relieves pain, overcomes deformity, and the symptoms subside. This suggests the perfection of mechanics. If the principle could be continued, and the patient allowed to exercise, the perfection of mechanical treatment would be attained. To accomplish this I devised the fixation lateral-traction splints.

To make the portable bed, place the child on a piece of paper; mark around him, with the limbs somewhat spread. Put this piece of paper on a board one-half inch in thickness, and cut the board to fit the pattern. Upholster the board with cotton batting, and cover with cotton cloth. A piece of rubber cloth is placed across the portable bed.

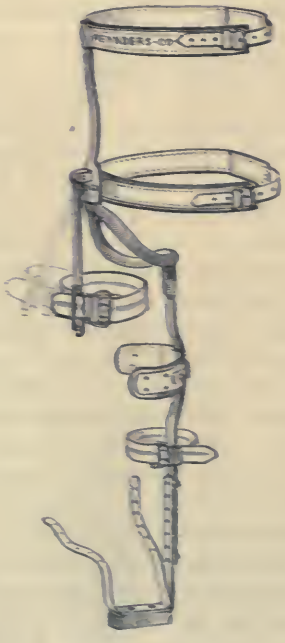
The child is laid on the board and enveloped with the plaster-of-Paris bandage from the foot to the axilla, to the thickness of one-half inch. When the plaster becomes set the front is cut away. The child is now removed; the bed is trimmed for the inside either by pasting flannel or rubber adhesive plaster over the plaster-of-Paris.

The child is placed on this and bandaged in. Extension is made to the foot-piece of the bed, and

lateral traction is made by means of the bandage passed around the leg and tied to the side. Figs. 3, 4, 5, 6, 7, 8, and 9 are representations of lateral-

FIG. 3.

FIG. 4.



traction splints, double and single; with inside and outside bars. Figs. 8 and 9 show the single and double splint adjusted.

The splint extends from the sole of the foot to the axilla, and is supplied either with an inside bar (Figs. 3 and 4) or with an outside bar (Fig. 6).

Instead of a strap passing around the perineum,

FIG. 5.

FIG. 6.

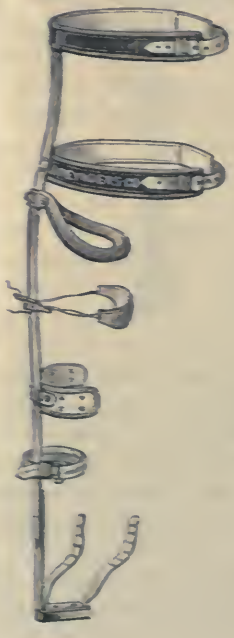


FIG. 7.

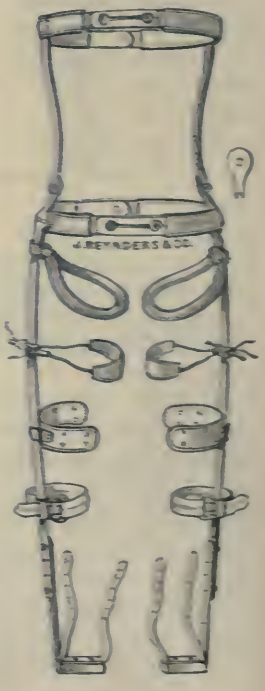

a steel ring is substituted, which catches the patient at the tuberosity of the ischium, and does not press upon the muscles.

Lateral traction is made in one splint by means of the lateral-traction lever (Figs. 3 and 4), and in the other splint by means of a strap tied to the side bar (Fig. 6); longitudinal traction is made as in the ordinary traction-splint. This splint im-

FIG. 8.

FIG. 9.

mobilizes the hip-joint, prevents the possibility of angular deformity, and applies traction so as to overcome spasm of the muscles that operate upon the thigh. The patient is never allowed to step upon this splint. Splints to immobilize the joint must extend above and below the joint. The long traction-splint stopping at the joint does not immobilize it, and the patient injures the joint by stepping upon it, as is evidenced by the almost constant increase in the deformity, observed in a considerable percentage of all cases.

It has been stated that patients wearing the splint extending up on to the thorax cannot sit down. This is certainly incorrect, as all of these patients can sit very comfortably on the side of a chair, with the diseased limb hanging over the side.

The crutches are an inconvenience; the long splint passing up on the body is an inconvenience, but the patient had better submit for a year or two to this slight inconvenience than to go through life with a deformed limb.

The Thomas splint, like the long traction-splint, only tells half the story. Thomas originally believed that the best result to be attained in hip-joint disease was ankylosis. Believing that prolonged rest would result in ankylosis, and that fixation of the hip-joint could only be accomplished by grasping the body above and below the joint (which is a fact), he devised the splint bearing his name. This splint extends from the axilla to the calf posteriorly. His patients recovered without angular deformity, but nearly all had shortening, many to a great extent, and abscesses occurred with astonishing frequency. A large number of cases presented to the British Medical Association by Mr. Sidney Jones showed that motion was present in nearly every case. Thomas's splint, not controlling muscular spasm, allows of great intra-articular pressure, resulting in destruction of the joint and the formation of abscesses.

Another serious objection to the Thomas splint is that the patient will step upon the foot. The splint, ending as it does at the calf, protects the limb only so far as the normal movements are concerned. If the splint extended below the foot, and the patient then attempted to step upon it, and if there were a perineal strap, he could not do so much damage to the joint.

My Results.

Cases received before the development of abscesses rarely develop them.

Small abscesses and effusions into the joint are frequently absorbed or heal by primary union after operation.

Discharging sinuses rapidly cease discharging unless there is extensive bone-disease.

Many cases recover with perfect motion.

All cases recover with but slight or no angular deformity.

Shortening of the limb does not increase, and cases of ankylosis I seldom see.

To conclude, my observations lead me to believe that one of the most serious elements of destruction in hip-joint disease is the trauma and pressure produced by muscular spasm; that fixation of the joint without extension is an impossibility; that the successful treatment of the joint must depend upon its absolute immobilization, which can only be produced by proper extension and fixation; that the constitutional treatment of hip-joint disease amounts to but little, independently of mechanical treatment; that mechanics is everything; that exten-

sion in the line of the axis of the shaft and in the time of deformity alone in hip-joint disease is entirely wrong; that extension should be made in a line parallel to the axis of the neck—in other words, two lines of extension—otherwise the idea of extension is not perfectly carried out; that ankylosis of the joint is not produced by immobilization, but by the severity and character of the inflammation; that the long traction hip-splints in general use neither properly extend nor immobilize the joint; that in a large percentage of cases the intra-articular pressure results in the destruction of the joint or in ankylosis, as is proved by statistics; that the results in hip-joint disease should be as good as those in knee-joint disease, and will be, provided perfect immobilization can be maintained; that patients should never be allowed to step upon any portative apparatus; that a high shoe on the well leg, and crutches, should be insisted upon until the patient is cured; finally, that the angular deformity seen in cured cases should not occur—such cases are a standing rebuke to the splint and methods employed. In other words, no patient with hip-joint disease need ever recover with angular deformity. In exceptional cases a slight degree of deformity had better be left than that resort be had to osteotomy or extensive myotomy.

SYPHILIS IN ITS RELATIONS TO THE REPAIR OF SURGICAL LESIONS.[1]

BY G. FRANK LYDSTON, M.D.,
PROFESSOR OF THE SURGICAL DISEASES OF THE GENITO-URINARY ORGANS AND OF VENEREAL DISEASES IN THE COLLEGE OF PHYSICIANS AND SURGEONS, CHICAGO.

I AM frequently asked whether a proposed surgical operation is safe, in view of the fact that the patient upon whom it is proposed to operate is suffering from more or less recent syphilis. I also find that general practitioners often advise patients that fall under my care against surgical operations, for the sole reason that said patients are affected with constitutional syphilis more or less remote.

I have been quite observant of the phenomena attending the healing of operation-wounds in syphilitic subjects, and I have come to the conclusion that *per se* syphilis has little or no effect in retarding repair. In many syphilitics I have had operation-wounds heal with exceptional promptness. An excellent illustration of the favorable course of simple incised wounds in syphilitic subjects is to be found in the excision of the primary lesion of syphilis. In a large number of cases of excision of hard chancre I have found that primary union was the rule. In mixed sores I have on several occasions seen reinfection and chancroidal ulceration following excision. I will state that these cases of mixed sores were operated upon entirely experimentally, as I do not consider it good practice to deal with such sores in this manner. In some cases —and in a far greater proportion than those that practise excision have acknowledged—induration of the cut edges will occur, but this only happens several days after primary union of the incision has occurred. If the operation be performed some days after the chancre has ceased to progress, and has become stationary, induration of the cut edges is not likely to occur. In some instances induration of the cicatrix will occur as a consequence of irritation a week or more after the incision is perfectly healed; but these untoward phenomena are not the result of imperfect repair, but are the result of a rapid proliferation of cells determined by irritation of the cicatrix after the process of ordinary tissue-repair is completed. The question of the possible local character of the chancre and reinfection of the cut surfaces enters into consideration in this connection, but does not concern us here.

In patients with latent secondary syphilis, suppuration, sloughing, and ulceration in operation-wounds are frequently attributed to the constitutional taint when the fault lies in the technique of the operation. Notwithstanding the fact that this explanation is very consoling to the surgeon, it is my opinion that a clean, aseptic operation in patients that are syphilitic, but in whom the syphilis is not in active efflorescence, will heal quite as promptly and perfectly as in entirely healthy individuals. This is not true, however, of suppurating and infected wounds; such lesions heal very slowly or not at all, until thorough and vigorous treatment of the constitutional malady is instituted. The difference between a clean, incised wound (that, when aseptically made and antiseptically dressed, is productive of little or no irritation from the first and of absolutely none after the lapse of a few hours), and pathological processes that produce continuous irritation, is very marked in syphilitic subjects. We know that the latent tendency of connective-tissue cells to proliferation and degeneration greatly exceeds the physiological limits when once the organism becomes tainted with syphilis; continuous irritation is prone to develop this latent energy of syphilized cells, with resulting prolonged suppuration, tissue-hyperplasia, ulceration, and perhaps sloughing. If we add to the irritating effects of the lesion itself the condition of sepsis, the morbid process is necessarily exaggerated.

When secondary syphilis is active and severe syphilides are present, any surgical lesion may determine a deposit of syphilized material at the particular point involved. This material may break down

[1] Read before the Chicago Academy of Medicine, July 10, 1891.

and ulceration of tissue result. So far as my observations go, it would, however, seem that this tendency is modified chiefly by the primary resistance of the patient, rather than by the severity of the syphilis, and I think it will be found that when once patients with active syphilis do badly, more reliance is to be placed upon tonics than upon vigorous anti-syphilitic measures. Virulent surgical processes, such as erysipelas, vaccinia, and chancroid, occurring in broken-down patients with constitutional syphilis, whether latent or active, are especially liable to determine a deposit of syphilitic neoplasm in the affected tissues.

With regard to the behavior of erysipelas in this respect, I will call attention to the fact that it has been recently claimed that erysipelas is curative of syphilis. I think that I am justified in being a little dogmatic regarding this particular point, as at the New York Charity Hospital, which has a number of pavilions devoted exclusively to cases of erysipelas, of which a large number are annually treated, I had exceptional opportunities for the study of erysipelas as seen in syphilitic patients. I have seen many cases of erysipelas occurring in syphilitic subjects, but I have failed to see any constitutionally curative effects from erysipelas; on the contrary, syphilitic patients that became debilitated by severe erysipelas were quite apt to be returned to the hospital within a comparatively short time suffering from an outcropping of syphilitic lesions. It was an experience so familiar as to be a matter of routine observation, that the sinus and suppurating surfaces remaining after phlegmonous erysipelas in syphilitic patients were very obdurate until constitutional treatment was instituted.

Horwitz[1] reports a case in which a patient with deep and extensive syphilitic rupia was apparently cured by a severe attack of erysipelas. The same author reports another case in which an ulcerating gumma of the leg was attacked and apparently cured by an attack of erysipelas. Neumann[2] reports two cases of a somewhat similar character. There is no question as to the accuracy of these observations. I do not admit, however, that such cases necessarily prove any antagonism between the streptococci of erysipelas and the germ of syphilis or its products. Erysipelas cures a simple ulcer, and the hard, callous ulcers of the leg, quite as readily as the syphilitic processes described by the authors mentioned. Not that I deny the possible antagonism of germs of various kinds, but I believe that in our microbic enthusiasm we are forgetting the relations of such processes as erysipelas and syphilis to tissue-nutrition. As is well known, it is not the poison of syphilis *per se* that prevents healing of syphilitic ulcers, but it is the local choking up of tissues with the syphilized cells. Erysipelas is for the time being attended by greatly exaggerated activity of the nutritive processes and a rapid breaking down and removal of the syphilitic neoplasm. Inasmuch as the syphilis has probably no directly corrosive action upon the tissues, and no effect at the site of the neoplasm other than that incidental to a heaping-up of rapidly proliferated material, the erysipelas runs essentially the same course as under ordinary circumstances. I am of the opinion that the cessation of active anti-syphilitic treatment and the substitution of the tonic and stimulant regimen so essential in erysipelas, has much to do with the beneficial effects of erysipelas in such cases as those described by Horwitz and Neumann. It is to be remembered that malignant syphilis is probably so not because of a high degree of toxicity of infection, but because of a high degree of constitutional susceptibility and lack of tissue-resistance. The effects of a germ of any variety depend on the condition of the soil in which it is implanted. To say that erysipelas is beneficial to the local process in patients suffering from syphilitic ulceration because the streptococcus of the one antagonizes the bacillus of the other—admitting for the sake of argument that syphilis has a bacillus—is the argument of *post hoc propter hoc* with a vengeance! If, however, we admit the clinical facts, and explain them by a modification of the soil, we are at least within the bounds of logic.

As to this point, although irrelevant to the immediate question in hand, it is worthy of note that in spite of all that has been said regarding the relation of the bacillus tuberculosis to consumption, and the action of the latest scientific phantasm, tuberculin, upon the disease, we are still brought face to face with the discouraging fact that we have no method of treatment to offer that is more reliable than that of our medical forefathers, who achieved their best results from measures that modify the soil in which the bacillus flourishes. There are few clinicians that, however enthusiastic they may be regarding the lymph-treatment, would not give more for measures of hyper-nutrition and super-oxygenation than for all the lymph ever manufactured. I would not pose as an iconoclast, but I think that we had better realize that there is much in the heritage of philosophy that the fathers in medicine have left us. Our hero-worship and our dalliance with strange gods is fast leading us away from the philosophical relations of medicine into the realms of medical sensationalism and fad-ism.

Vaccination of subjects recently syphilitic is apt to be followed by unpleasant results. In this connection I recall a case in which I vaccinated

[1] THE MEDICAL NEWS, March 21, 1891.
[2] Allg. Wiener med. Zeitung, 1888.

a gentleman who, for about three months, had been under treatment for syphilis. For a short time the vaccine vesicles ran their ordinary course; they finally dried, but pus formed beneath them, and ulceration progressed until a perfectly typical syphilitic ecthymatous ulcer resulted. This extended to the size of a half-dollar and did not yield until I substituted the mixed treatment for the mercury that the patient was then taking. Aside from his syphilis this patient was healthy, and as he was taking mercury in small doses, there is no question in my mind as to the relation of the syphilis to the ulceration. In this connection the question arises whether such instances do not explain many cases in which the accusation of having used impure virus is made against the physician. In children with hereditary syphilis, such a case might lead to results very embarrassing to the physician. I have in mind the case of a practitioner that narrowly escaped a malpractice suit at the hands of the parents of a child that, it was claimed, lost its eyesight as a result of a syphilitic keratitis following vaccination with impure virus. Knowing the gentleman that had vaccinated the child, and being assured by him that he had used bovine virus obtained from a reliable firm, and furthermore, being rather skeptical as to the possibility of the existence of the syphilized heifer, I took some pains to inquire into the case. I found that the vaccinia had run its usual course for about two weeks, when transformation into an ulcer occurred, and it was less than two weeks after this that the trouble with the eyes developed. This alone was enough to exculpate the physician, and if it were not, the cachectic aspect of the child, the peculiar appearance of its teeth, and the absence of axillary bubo certainly proved innocence. It required very little argument upon my part to convince the father of the child that it was best not to take his case into court.

Chancroids occurring upon syphilitic subjects are likely to become phagedenic, and gangrene is likely to occur in patients broken down in the period of sequelæ from over-treatment and the disease in combination. I am inclined to think that over-active treatment has more to do with the constitutional condition and tissue-depravity than the syphilis.

I have had a rather limited experience in fractures occurring in syphilitic subjects, but I have not noticed any difference between the rapidity and thoroughness in repair of otherwise healthy subjects with secondary syphilis and the rapidity and thoroughness of repair in absolutely healthy patients. I have in several instances observed bad results in cachectic and intemperate syphilitic subjects. Such cases seem to be especially prone to necrosis and non-union. I have seen one case of necrosis of the humerus, following a fracture in a syphilitic subject, in a man who absolutely disregarded my advice and kept himself comfortably intoxicated for some weeks following the injury. This case finally went out of my hands, and I know nothing of its subsequent history. In another instance I observed non-union of a Pott's fracture in an intemperate syphilitic subject, but in both of these cases I attributed the unfavorable result to constitutional depravity induced by dissipation rather than to the syphilis *per se*. In the period of sequelæ, or the so-called tertiary stage of syphilis, operation-wounds and surgical lesions are liable to pursue an unfavorable course as a consequence of one or all of three conditions:

1. Profound syphilitic cachexia, due to the prolonged and secondary severe stage.
2. The abuse of mercury.
3. The condition that often prevails—alcoholism.

Operations about the mouth, naso-pharynx, and fauces during the active period of syphilis have, in my experience, been attended with some disagreeable results. Clean incised wounds are rarely made in operating in these localities, and it is well-nigh impossible to keep wounds of these parts in a perfectly aseptic condition, or free from irritation. Rest is also difficult to secure. In the case of the mouth and pharynx, the contact of the food and the movements of chewing and swallowing are sufficient not only to aggravate mucous patches and ulcers, but even in perfectly healthy individuals often serve to develop ulceration in wounds of these parts. In syphilitic patients, typically specific ulceration is apt to follow surgical lesions. Excision of the tonsils in syphilitic subjects has, in my experience, several times resulted in obstinate ulceration. An illustration of this has recently come under my observation. A gentleman that had been under my care for syphilis for nearly two years, but in whom no lesions had been observed for eighteen months, came to see me in regard to several ulcers on the inner surface of the lower lip. These had the appearance of typical gummatous ulcers, one of them being quite deep and ugly-looking. On inquiry I found that these ulcers followed a blow upon the mouth that caused laceration of the mucous membrane by the teeth at the site of the ulcers.

I have seen several cases in which laceration of the gums by the dental forceps, in the careless extraction of a tooth during the active period of syphilis, had caused ulceration of a typically specific character. In one instance I noted extensive ulceration of the palate, apparently precipitated by laceration of the gums in the removal of tartar. Crushing injuries are apt in syphilitics to be followed by ulceration of a typical character. I have seen several cases of onychia syphilitica, with loss of the nail resulting from crushing of the end of the finger.

Operations upon the cartilaginous and bony structures of the nose in syphilitic subjects are apt to be followed by slow healing, and perhaps ulceration of the operation-wounds. Lack of rest and the contact of irritating secretions in all such cases afford sufficient explanation. Bruising of the periosteum and bone is likely to be the determining factor in the production of a node. Ulceration and caries or necrosis are, of course, thus more likely to result than in syphilitic nodes and osseous inflammations occurring independently of traumatism.

In broken-down syphilitic cases suffering from operation-wounds and injuries, my experience has led me to exercise great caution in the exhibition of anti-syphilitic remedies, and I have come to regard the general condition of the patient, independently of his syphilis, as of much more importance than the old constitutional infection; in other words, I find much better results from treating the patient than from treating his syphilis.

The question of the influence of the syphilitic dyscrasia upon the repair of operation-wounds was brought to my mind not long ago by the protest of a physician against my operating upon a case of syphilitic necrosis of the tibia. The physician thought that an operation was unwarrantable, and that repair of the bone and of the operation-wound would not be likely to occur until the patient had had a thorough course of mercury and iodide of potash. The patient has not yet made up his mind upon the question of operation, but most practical surgeons will bear me out in the assertion that an operation will be the surest method of treatment for the patient's general condition.

A case in point is one in which I operated for central syphilitic necrosis of the tibia involving the entire shaft of the bone for about four inches. The question arose in council as to the propriety of operation until after vigorous anti-syphilitic treatment for a few weeks. I advised immediate operation, which was finally consented to. After removal of the necrotic bone I applied a fenestrated plaster bandage, put the patient upon cod-liver oil, and allowed him to go out on crutches. Repair was quite rapid, and at the end of three months the patient was able to get about without artificial support and had gained about twenty pounds in weight.

GUMMATA OF THE BICEPS BRACHIALIS, KIDNEY, AND EPIDIDYMIS, SIMULATING MALIGNANT TUMORS.[1]

BY GEORGE NOBLE KREIDER, A.B., M.D.,
OF SPRINGFIELD, ILLINOIS.

INSTANCES of syphilis involving either muscle or the kidney are sufficiently rare to justify the report of a case involving these parts, and also affecting the epididymis. At least two members of the profession, occupying prominent positions in St. Louis and Chicago, failed to make a correct diagnosis in this case, and advised operative procedure. A case of a somewhat similar nature recently passed through one of the hospitals of Paris, France, without a correct diagnosis having been made, and the true nature of the disease only became known by the bad practice of a charlatan, who applied a salve to the tumor on the thigh, causing ulceration. The tumor became no smaller, and the ulceration increased in size; under these circumstances the patient applied to the Hôpital Saint-Louis, where the syphilitic character of the ulceration was recognized and the tumor was dissipated by proper treatment.

The history of my case is as follows:

T. D. S., thirty-four years of age, on February 15, 1891, was brought to my office for consultation by Dr. Steenberg. The patient had passed through the hands of a number of medical gentlemen, who, without benefit, had given him medicine, and several had advised operative procedure. All had pronounced his case unusual and obscure. I obtained the following history: His father served in the war, came out of service with a running sore in his side, and died with something like consumption, aged forty-five years. His mother, fifty-one years of age, is living and in good health. Brothers and sisters are all living and healthy. The man had been ailing for about four years. He complained of pains in the bowels, and had some trouble with the bladder. He was relieved by injections of morphine. After an attack of this kind, small white lumps, like cheese, came from his bladder. These white lumps could be broken down between the fingers, and he was told that they were a kind of gravel. He had gonorrhea eight or nine years ago, but denied having anything like syphilis. This clap lasted about a month. A lump in the left testicle was the first of his present troubles. That appeared before he had the attacks of gravel; at one time it broke down and discharged. He has recently had no bladder-symptoms except frequent micturition. The tumor of the kidney on the right side was second in order of appearance, and has been called floating kidney, or consumption of the kidney. The third tumor was that on his arm; it appeared about a year ago, and has slowly increased in size. His greatest trouble at this time is soreness and partial paralysis of the arm, and frequent urination. He has no distinct chills, but at times has chilly sensations. He has never had any cough; there is no flushing of the cheeks; the skin is sallow and dusky; his bowels are constipated. He is married; has one boy, nine years old; his wife miscarried seven and five years ago, and has not been pregnant since.

His present condition is: height, 5 feet 10 inches; weight, 129 pounds; pulse, 94. He weighed 150 pounds before he was taken sick. The urine is of a light-straw color, acid in reaction, and contains no albumin or sugar.

[1] Paper read at Forty-first Annual Meeting of the Illinois State Medical Society, May 21, 1891.

In the belly of the left biceps brachialis there is a sharply defined tumor, 3¼ inches long. The circumference of the left arm over the largest part of the tumor is 10 inches; of the right arm at a corresponding point, 9 inches. The measurements of the left forearm show a diminution from ½ to 1 inch in all circumferences, indicating a certain amount of atrophy from disuse, and confirming the patient's statement of partial paralysis. The tumor is smooth, firm, freely movable, and easily defined; is not painful on pressure. There is considerable disability of this arm, as the man cannot get on his coat without assistance. There are no enlarged superficial glands in the axilla or elsewhere.

About 3½ inches above the spinous process of the right ilium there is a smooth tumor lying obliquely and apparently connected with the kidney. It is dull on percussion, slightly tender to the touch, movable, and measures about 3¼ inches long by 2 inches wide. Auscultation and percussion of the lungs show them to be normal. There are no other evidences of tuberculous disease. The liver is normal in size, but tender at the lower border. On turning back the prepuce a slight scar was found, and he confessed that he had had a sore there. There are no syphilitic nodes on the tibia, and no evidences of syphilis in skin or mucous membranes. The sight and hearing are good. The left testicle shows an enlargement of about the size of a large hazel-nut, which is connected more particularly with the epididymis. It is very hard and not painful to moderate pressure. The diagnosis was made of syphilis of the muscle, kidney, and epididymis, and I recommended treatment by inunctions of blue ointment and the internal administration of anti-syphilitic remedies. The reasons for this diagnosis were: first, the scar on the penis; second, Keyes's statement that syphilis appearing in the muscles elects the left biceps brachialis; third, the absence of all signs of tuberculosis in lungs and abdomen; fourth, the absence of the cachexia of malignancy.

On my recommendation the treatment was carried out by Dr. Steenberg, and he informed me that in about thirty days the tumor on the arm had softened, and was opened with the knife. Granular matter and a yellowish syrupy substance were discharged in large quantities.

I saw the patient March 22d, five weeks after treatment was begun. The left arm then was of the same circumference as the other, and there was still some of the typical discharge. This microscopically proved not to be tuberculous or actinomycotic. The cavity was cleansed, and at the last examination there remained only a minute sinus. The tumor in the right abdominal cavity was apparently diminished in size and was less movable. At the examination made April 27th, I found that the patient had gained 12 pounds in weight, and was feeling much better in every way. He has regained the use of his left arm, and can put on his coat without assistance. The swelling of the kidney has still further diminished in size. The frequent urination has entirely disappeared. The man was at this examination confronted with the statement and proof of the character of the disease. He stated that he did have a sore and discharge twelve years ago, but was told that it was the clap. He was treated by inunctions of some blue salve. The son, first seen at this time, is rather small for his age, has a large head, dry, lifeless hair, worm-eaten teeth, and rheumatic pains in the limbs.

The conclusions from a study of this case and the results of treatment are:

1. This man was undoubtedly affected with syphilitic gummata of the muscle, kidney, and epididymis, appearing ten years after the primary infection.

2. The first development of the disease was extremely mild, and beyond a very slight scar on the penis left no marks on any part of the body.

3. That the indifferent use of specific medication served to check the disease, and during the time of temporary quietude of the poison he was married and became the father of a son.

4. The son shows only slight manifestations of hereditary disease.

5. The disease afterward developing without treatment, his wife became affected, miscarried several times, and has finally ceased to conceive.

6. Despite the fact that no correct diagnosis of his trouble was made, and that proper treatment was not applied, the disease ran rather a slow course, and now as a result of proper medication the man bids fair to make a complete recovery.

The medical literature bearing upon the subject is so scanty, that I am led to make the following synopsis of articles that I have been able to collect.

M. Feulard[1] has reported the case of a man, thirty-seven years of age, who was afflicted with an enormous gummy tumor of the left triceps femoralis, which had been entirely cured by specific treatment. The tumor had existed for two years, and followed a slight traumatism. He entered a hospital, where amputation was advised. Frightened by this, he consulted a charlatan, finally entering the Hôpital Saint-Louis, where the form of the ulceration was recognized as syphilitic and properly treated. His wife remains healthy in appearance, protected by the law of Colles-Baumés. In the first three years of marriage she had three miscarriages; the fourth child, born eighteen months after the last miscarriage, is seven years old, and is distinctly hereditarily syphilitic.

R. Kohler[2] has reported a case in which a man with a peculiar growth in the left hypochondrium was operated on by eminent surgeons. The mass was at first taken for a tumor of the spleen and then for a sarcomatous growth of the walls of the abdomen. Finally the diagnosis of syphilitic gumma was

[1] La Semaine Médicale, 1891, page 54.

[2] "Diagnostische interessante Geschwulst," Deutsche militärärztliche Zeitschrift, 1890, p. 601.

made, the patient put on proper treatment, and cured.

Neumann's[1] patient, thirty-five years of age, thirteen weeks after infection presented in the muscles gummata that were not adherent to the skin. Six different muscles were affected. Some of these gummata suppurated, some were absorbed. There was no pain and no retraction after the disappearance of the growths. The movements of the muscles were in this case completely restored. These gummata appeared very early in the disease.

Bier[2] describes 121 cases of syphilis of the muscles, and says that they offer great difficulties in diagnosis. The clinical picture is very changeable and different. The point of predilection, he says, is in the sterno-cleido-mastoid; others say the biceps brachialis. These tumors frequently start from an injury. Bier warns us not to judge too hastily when specific treatment fails to cure these cases, because they often get well after all hope has been given up, especially when they have existed for a long time without treatment.

In Kohler's[3] case there were tumors that had the appearance of syphilis of the muscles, but which also contained actinomyces. The woman died from exhaustion, but the post-mortem examination left it in doubt whether or not there was a mixed infection of syphilis and actinomycosis.

Schnitzler[4] presented to the Imperial-Royal Society of Physicians at Vienna a case of this sort, very interesting from a diagnostic point of view inasmuch as the different eminent authorities that had examined it differed widely in their views. There was a growth on the tonsil and palate that Schnitzler and others thought was cancer, but Kaposi, Billroth, and most of the members diagnosticated syphilis.

Bramann[5] presented to the Berlin Medical Society two patients with syphilitic tumors in the muscles and stated that these tumors usually appear in the latest stages of the disease, twelve to twenty years after the infection. They are often difficult of diagnosis, being near the bone, so that many think that they arise from the periosteum, but oftener they are in the middle of the muscle. In one of the cases presented there was a tumor in the side of the neck, and another in the region of the clavicle. This case presented no other signs of syphilis. In the second patient there was a so-called myositis fibrosa, the tumor extending from the base of the skull to the clavicle. The patient was forty years of age, and was infected fourteen years previously. Both were cured by specific treatment.

Köbner[1] presented to the Dermatological Society of Berlin a patient, aged fifty-eight years, suffering with syphilitic disease of the muscles that had existed for eleven years. The left sterno-cleido-mastoid was diseased in its entire length, especially near the clavicle. The muscle was prominent, hard, and painful.

Spontaneous pains, especially at night, did not exist. The corresponding muscle on the right side was only diseased in its lower third, where there was also a tumor. These tumors developed gradually. The patient had been married twenty years, and had borne nine living children. She was infected by her husband, who had a chancre twenty-three years previously, but no further evidences of the disease. She was cured in three months.

Karewski[2] states that in the muscles of the tongue, in the testicles, and in the mammæ, syphilitic tumors occur of which the diagnosis offers certain difficulties. They are especially worthy of the study of the surgeon, because they are usually mistaken for the malignant tumors that have their seat of predilection in these organs. Especially weighty is this question when the new-growths attack the muscles of the skeleton, in which, if malignant, they would require extensive operations, while, if a correct diagnosis is made, they can be easily dissipated. No muscle is free from this disease. The sterno-cleido-mastoid was affected most commonly. The diagnostic point is the well-marked border. These tumors can be accurately defined from the surrounding tissue. Exacerbations of the pain often occur at night. Traumatism often causes the growths. The disease, when seen in the tongue, is most frequently mistaken. In the testicle the differentiation from tuberculosis and cancer is not easy. Syphiloma of the mamma is the least common, but Karewski has seen an example in the male mamma, and has removed the condition by proper medication.

According to M. Mauriac,[3] syphilis can attack the kidney at all periods of its evolution. The lesions are similar to those of Bright's disease; they rarely assume the form of gummy tumors. Syphilis of the kidneys may appear early or late in the disease. When early it corresponds to the acute infectious diseases—that is, it is parenchymatous. The chronic forms are more grave and do not respond as well to treatment.

Tommasoli[4] has seen changes in the kidney dur-

ing all stages of syphilis; sometimes the symptoms of Bright's disease were present, sometimes only albuminuria. Anatomically he has also seen the greatest variety of pathological conditions, excluding amyloid degeneration. He makes two groups: one occurs in the first year of the disease, the result of an acute syphilitic intoxication; in these there is less tendency to chronicity and the prognosis is better. The second group covers the whole series of chronic interstitial inflammation of the kidneys, the course and time of appearance of which vary extremely. Mercury and potassium iodide and diet are recommended in their treatment.

O. Pinner[1] states that syphilis may occur as a distinct disease of the epididymis. The tumors that form vary from the size of a bean to that of a nut, and are as hard as cartilage. This disease is not frequent, having been observed in thirteen of 2200 cases of syphilis.

C. Schadeck[2] states that syphilitic disease of the epididymis was first described in 1861 by Engelstaedt. It occurs without involvement of the testicles and in the early as well as the late stages of the disease. It occurs most commonly from one to five years after the infection—at the same time as the other forms belonging to the condylomatous period. tact. It is seldom that orchitis is followed by epididymitis. Syphilitic epididymitis begins with a swelling that is soft; later it is hard, and attains the size of a plum. It may attack one or both sides, but seldom both. Its course is very tedious.

NOTE.—Since the foregoing was written a case of syphilitic disease of the kidneys has come under my notice and deserves to be placed on record. The man was seen in consultation with Dr. L. C. Taylor, of Auburn, Ill., August 15, 1891, and has since been under his care.

C. R., thirty-six years of age, a horse-trainer, with a good family history; he was not intemperate; the pulse and respiration were rapid. The abdomen was largely distended and respiration in consequence greatly impeded. The scrotum was edematous and as large as a child's head. The lower extremities were swollen almost to bursting. The urine was nearly solid with albumin, and a large number of tube-casts were found by both Dr. Taylor and myself. Over both tibiæ were large brown scars, with a history of chronic ulcers in the same situation some two years previously. These led to the diagnosis of syphilis, which was confirmed by the patient's confession and by a small linear scar on the dorsum of the penis. The patient had denied syphilis to Dr. Taylor, who suspected it, and so had not had specific treatment. The condition of the patient was apparently so desperate and the prognosis so unfavorable that we did not make as accurate notes as would now be desirable. The patient states that he had syphilis some fifteen years previously, and has had no secondary symptoms. The ulcers on the limbs were treated by means of potassium iodide, and were cured after a long siege, but neither he nor his medical attendant suspected syphilis. The diagnosis of specific disease being safely established, the man was put on mercurial inunctions and injections and anti-syphilitic treatment. Multiple punctures were made in the limbs and scrotum. In a few days the periosteum of the left tibia became very much swollen in two places, and incisions being made a large quantity of serum was drained off, reducing the limb to about the normal size. Only one hypodermatic injection of mercury was given, because of the condition of the skin. Mercurial inunction was faithfully kept up. Dr. Taylor informs me that the man's condition has constantly improved. The tube-casts have disappeared and the percentage of albumin has diminished until only about ten per cent. remains. His appetite is ravenous and the prognosis for a complete recovery very promising. He was about and attending to his business within sixty days after the consultation—at which time death did not seem more than a few days distant. This case proves that so-called Bright's disease of the kidneys may be of syphilitic origin, and that specific disease should be sought for in all cases of this character.

ON THE TEACHING OF ANATOMY TO ADVANCED MEDICAL STUDENTS.[1]

BY HARRISON ALLEN, M.D.,
PROFESSOR OF ZOOLOGY AND COMPARATIVE ANATOMY IN THE UNIVERSITY OF PENNSYLVANIA.

THE importance of anatomy to the physician and surgeon has caused the method of teaching this science to be largely determined by practitioners. The student is taught the elements of histology, the shapes and numbers of organs, the outlines of regions, and their mutual relations. Other facts than those named belong in a very remote degree to the needs of practice; and when the great number of medical topics is considered, which is of necessity brought to the attention of the student, it is no wonder that governing bodies are disposed to disregard all phases of instruction that do not have direct claim upon the physician's time and service.

But science is rarely pursued for practical good. The acquisition of knowledge for its own sake—the determination of general principles that reveal the existence of law—awakens and maintains pleasures and interests in the mind of the anatomist compared with which the practical uses that he can make of the knowledge appear to be poor and mean. With as much propriety one might say that navigation is the highest use that can be made of the study of

[1] Read before the Association of American Anatomists at its third annual meeting at Washington, D. C., September 24, 1891.

astronomy, as to assert that the chief end of the study of anatomy is to apply its tenets to medicine. These statements are made not to lessen the dignity and importance of practical work, but respectfully to claim that such work does not comprise all the value, or even more than a small fraction of the value, that pertains to the whole.

In his *New Atlantis*, Lord Bacon says: "We have three of our fellows that bend themselves, looking into the experiments of others, and cast about how to draw out of them things of use and practice for man's life, and knowledge, as well for works as for plain demonstration of causes, means of natural divinations, and the easy and clear discovery of the virtues and parts of the bodies. These we call dowry-men or benefactors. Lastly, we have three that raise the former discoveries by experiments into greater observations, axioms, and aphorisms. These we call the interpreters of nature."

I hear a response to the foregoing statement that the structure of animals exhibited on a broad scale is already taught to classes in the scientific schools, and that, in the scheme of a university education, the biological subjects are as well advanced as any others in the curriculum. This is an imperfect, if not misleading, presentation of the facts. It is true that the rudiments of the structure and functions of animals and plants are taught. But to students already advanced by general training and by preliminary work in natural history, little is presented that prepares them to discuss the more intricate problems.

To my mind the scheme of university work is unsatisfactory until opportunity is afforded to men, who, after completing their biological and medical training, may desire to still further advance. Conceding that the question of maintenance has been settled, either by the possession of private means or by endowment of fellowships, what courses of instruction are afforded these advanced men? As a rule, nothing, or next to nothing. It is customary for such novitiates to reside abroad for several years, where amid numerous centers of learning are found one or more masters, the disciples of whom they become. The advantages of travel being considered, it may be said that with the comparatively easy means of obtaining the best instruction the present scheme is on the whole adequate. With such a conclusion I cannot agree. If it were true, we might in reason have stopped long ago in our lines of university expansion. Independence in intellectual as well as in political life should be the object of American citizenship.

First, and always, let us remember that medical investigators are those it is desired to train. It is for men that are already imbued with the desire to pursue their researches in anatomy that I appeal. They stand in this field with what preparations can be given them for usefulness. They are medical biologists—medical anatomists. They are not restricted to the problem of the relief of suffering, and yet they are occupied with those other problems upon which the true solution of all depends.

For such instruction I would have a specially-designed museum and a specially-equipped laboratory. It may be assumed that in every great medical school, from among the large number of matriculates (men already trained and of the best quality), two or three of the type described will present themselves for an advanced course in anatomy. I am prepared for the objection that this is too large a number. But, so far as I know, no one has attempted to ascertain how many men in each class of graduates would come forward, and my impressions are based upon the number of workers in the general field of biology—some of whom, at least, would have pursued these or similar studies had any systematized course been presented to them. I will, therefore, begin with three men a year. To this number may be added as many young teachers, tutors, curators, and prosectors, who would avail themselves of the instruction. The work might be initiated in either of the halls of biology or of medicine. If the course were well established, it would be well to institute a laboratory and museum distinct from any on the university grounds. I am of the opinion that the administrative success of such separation of collections would be assured. All must approve of the ethnological collection of Harvard being distinct from the Museum of Comparative Zoology, and of both in turn being set apart from the museum in the Medical School. In like manner I assume that there is no reason why series of specimens arranged in illustration of principles that are not taught either in the preliminary or in the proper medical courses, should be necessarily connected with one or the other museum. The collections should be in the main designed to accommodate the preparations that are used in the illustration of general lectures. Museums that teach by the specimens being removed from the cases to the lecture halls are radically distinct from museums that teach by the conservation of series that are arranged and labelled for instruction as they stand, and which should be rarely, if ever, disturbed.

The following, treated in some detail, embrace the topics that occur to me at this time as appropriate subjects for instruction: The study of the human brain; especially the study of the mammalian and avian brains, both of the gross and the minute anatomy, the localization of functions, etc. The study of muscular anomalies and their homologies in the normal myology of the vertebrates. The study of animal locomotion and its

application to the morphology of the vertebrate limb, and in general the application of photographic methods in studying animal locomotion.[1] Studies in craniology, especially the comparative studies of human and mammalian crania. The study of osteological variations, with a similar application to the normal anatomy of the lower animals and the beginning of morbid processes. The study of nutritive processes on tissue as correlated to age.[2]

In addition, courses of experimental morphology might be essayed. Such investigation could be encouraged without encroaching on the domain of physiology, as the votaries of this science somewhat arbitrarily restrict it. Indeed, much of the study of animal locomotion would be experimental, as would also be the study of protoplasm in viscid media, under rotation, compression, etc. The effects of light, temperature, water in motion and at rest, etc., on organization, would naturally find a place. Experiments on mutilation of embryos might also be undertaken.

Lectures on correlation of structure, on vegetative repetition, on the relation existing between phyllogenetic and teratological processes, could be given, as well as the study of the laws of heredity, especially in attempting to answer the question of the transmittal of acquired characters.

The teeth are so responsive to the constitutional peculiarities of the individual that their peculiarities can be seen and readily detected. The method of procuring accurate impressions can be applied and the plans of preserving the form of teeth be easily accomplished.

As is known to the zoölogist, the parts involved in the act of mastication are important in the classification of the mammalia, the slightest departure in the form, number, position, and rate of development of the teeth being for the most part correlated with other variations in the economy, while the shapes of the lower jaw and of those portions of the skull that afford surfaces for attachment of the masticatory muscles are of importance. No structures of the body resemble the teeth in the character of their response to morbid impressions; no other organs are arranged in progressive series; and none other than these are evolved after birth. Hence the effects of disease and accidents to which the teeth are subjected are sure to be recorded in the shapes of the crowns and roots.

If the student of heredity were to have placed at his disposal a collection of the casts of the permanent teeth of three generations—that is to say, of the parent of the subject, the subject himself, and the children of the subject—and if a clinical history were secured of the diseases and accidents that these persons had incurred, a tenable argument might be established as to the significance of the contrasts or resemblances in the forms of the teeth.

Thus, if three generations were expressed by the letters A, B, C, and if B is the subject of an acquired character (let us say from scarlet fever or measles), the new form of structure seen in the second and third molars may be transmitted to C. But in order to prove this it is necessary to know the peculiarities of these teeth in A. Hence, the teeth of the ancestors and descendants of the person who exhibits the acquired character must be known. A somewhat similar plan of observation could be made on the teeth of the lower animals. It is strange that those teeth with endless pulps, in which growth is rapid and interference with their relations causes permanent records to be made in malformation, should not have been used in studies of nutrition.

In connection with myological studies a number of minor problems suggest themselves; such, for example, is the nature of white and red muscles. It has been noted that in ostriches that have been confined in zoölogical gardens the muscles of the leg undergo fatty degeneration and become white in color; it is also known that the pectoral muscle in many of the gallinæ is white, presumably from the fact that they are used but for short and infrequent flights. How evident is the conclusion that a systematic study of all muscles of active birds living in enforced confinement, as compared with the relatively active muscles in feral forms, might be undertaken with a fair prospect of throwing light upon the nature of the process, and with a hope that the subject of fatty degeneration (even if by this method not elucidated) may have its study placed on a broad basis by subjecting its tenets to the tests of systematized experiment and observation!

The morphological study of the results of diseased action might also be undertaken. The differences that obtain between normal individuals and those the subjects of hereditary disease must be of importance to the anatomist and the pathologist.

[1] Instantaneous photographs have given us definite conceptions of the behavior of the manus and pes in terrestrial and aërial movements. I had the honor to point out as a result of a study of the negatives taken by Mr. E. Muybridge under the auspices of the University of Pennsylvania, that the ground is touched by the outer border of the foot and is left by the inner border, and that the impact represented by this transition is expressed by an oblique line that extends from without inward (ecto-entad) across the metapodium. Prof. H. F. Osborne by studying the carpus and tarsus in extinct forms of mammalian life has found that this conclusion is of value in studying the evolution of the parts. From this we can conclude that, as a result of a photographic plant in connection with advanced anatomical work, discoveries could with some confidence be anticipated.

[2] This would form a morphological study on the nature of age, and would more particularly embrace a consideration of the immature and senile forms as compared with the typically adult, as well as the retention of juvenile characters in the adult.

The variations in the forms of the bones, as found in medical museums, are of a character that suggest their relation to inherited causes. Every clinical observer has noted the peculiar shape of the chest in families in which pulmonary phthisis is hereditary, even though the special tuberculous deposits are absent in some of its members. The clubbing of the finger-nails is a sign of the same disposition. Some writers, indeed, claim that in this class of subjects a special arrangement of the fibers of the pneumogastric nerve exists. Are these and similar morphological characters susceptible of being also gathered so as to contribute to the discussion of the transmission of acquired characters? Are not opportunities here presented for the medically trained biologist to study the subject of heredity in a line so important and, alas! with material so abundant? Other hereditary diseases, such as struma, syphilis, and gout, are less strongly marked than is the tuberculous, but even on this obscure horizon landmarks are detected that are of sufficient definiteness to guide the observer to well-defined plans of study. The animals of zoölogical gardens exhibit examples of acquired struma, the effects of which more especially distinguish the skeleton. Can any of these characteristics be transmitted? How would the skeleton of a tiger, let us say, born in captivity in the third and fourth generation differ from that of a feral type? After what manner may one expect taxonomic characters modified in these generations of prisoners?

The nature of malignant growths, it is not improbable, would find a solution in a line of research based upon a similar proposition. What proportions of malignant growths, such as the sarcomata, are met with in the feral state of quadrupeds as compared with those in the domesticated or the captive state? Can experiments be devised by which we may expect to cause these growths to appear by creating the favoring conditions? Can we study the genesis of the sarcomata to better advantage than has hitherto been done, by outlining the biography, the lineage, and to some extent possibly the destiny, of these tumors, by applying to them experimental methods of research?

Medically trained men are not apt to become pure morphologists. The underlying thought is of *function* through which *structure* is modified. In its best sense, therefore, Physiological Anatomy is the branch of science that would be most developed. Let us suppose that John Hunter had lived in 1891 and had essayed his work by all the aids of modern science, and had undertaken a plan of investigation for the continuation of his labors: might he not have accepted some such scheme as I have here feebly attempted to portray? With the admiration we feel for his genius, let us not only have Hunterian orations, but in each medical center a Hunterian laboratory and a Hunterian museum.

"I am so utterly opposed to those cloud-builders who would divorce physiology from anatomy," says Haller, "that I am persuaded that we know scarcely anything of physiology that is not learned through anatomy." (Quoted from R. Cresson Stiles's *Life and Doctrines of Haller*, New York, 1867.)

In Solomon's House in the *New Atlantis*, in which Bacon essayed a scheme for intellectual advancement, we read of "parks and enclosures of all sorts of beasts and birds, which we use not only for view or rareness, but likewise for dissection and trials, that thereby we may take light what may be wrought upon the body of man; we have also particular pools where we make trials upon fishes, as we have said before of beasts and birds."

I hear objections that this scheme is visionary and impracticable. How is the money to be obtained by which it can be rendered feasible? Where is the teaching-force to be recruited? My answer is that if the need of establishing such a course be acknowledged, the accomplishment of the end in view is no more difficult than in any other branch of pure science. A few years ago the establishment of seaside laboratories would have been thought chimerical. Now they are assured successes.

If I am told the results obtained will appeal to but few, I reply that important projects must be supported in proportion as they so appeal, until such time as they shall have proved their right to exist.

CLINICAL MEMORANDUM.

A CASE OF GLANDERS.

BY WILLIAM S. BARKER, M.D.,
FORMERLY ASSISTANT PHYSICIAN AT THE ST. LOUIS CITY HOSPITAL, ST. LOUIS, MO.

L. W., colored, eighteen years of age, has been employed removing ashes, slops, etc. He entered the City Hospital November 17th. His mental status was quite low, so that his previous history was scarcely obtainable. There was no evidence of any venereal disease, and he gave no history of injury. He stated that two weeks previously to his admission he first noticed a swelling on his forehead over the frontal sinus; that considerable coryza soon set in; that he picked at the swelling, which increased and soon involved adjacent parts. On his admission, some days later, there were irregular nodules about the central and lower parts of the forehead. These proved to be pockets of pus, the skin being intact over them. There was much edema about the eyelids, extending to the nose and cheeks. There was a small break in the skin over one of the nodules on the forehead, and, by pressing upon the swollen parts below, pus was forced through this opening above, showing rather extensive purulent infiltration. It seemed that systemic disturbance had not been very

great heretofore, but it became so now. The temperature was 101°. Two days after his admission the man complained of pain and of impaired function at the right elbow. On examination a small semi-fluctuating swelling was found on the flexor side of the right elbow. The temperature next day rose to 104°, and his condition became steadily more aggravated. Pus was found in the swelling at the right elbow. Two days later peculiar pustules appeared in various parts of the body, varying in size from that of a pin-head to that of a five-cent piece. The numerous lesions were all covered with epidermis and extended quite deeply, containing a milk-like pus. These were incised. The older lesions on the forehead and nose had now assumed a very repugnant character, the tissues all steadily sloughing away in a horrible manner. Latterly delirium was pronounced. The patient died November 28th. On post-mortem examination one lung presented an extensive purulent focus. Dr. Bremer, of St. Louis, made a microscopic study of the contents of the pustules and confirmed the diagnosis of glanders.

MEDICAL PROGRESS.

Surgical Treatment of Pulmonary Gangrene.—OEHLER (*Münchener medicin. Wochenschr.*, No. 41, 1891, p. 723) has reported the case of a robust man in which pulmonary gangrene developed in conjunction with pleuro-pneumonia. As at the end of two and a half years the man's forces were progressively failing, the dyspnea increasing, with recurring rigors, an exploratory puncture with a hollow needle was made, but with no result. Shortly afterward the patient was anesthetized and the seventh rib resected at the point at which the signs of the existence of a cavity were most distinct. In the course of the operation the pleura was opened, and pneumothorax resulted. The operation was suspended, a drainage-tube was placed in the wound, and a firm bandage was applied. The man recovered promptly, and in the course of a few days the pneumothorax had disappeared. At the end of four weeks an incision was made at the site of the first operation, the now adherent pleura and the lung to a distance of two inches entered by means of a Paquelin cautery, but further interference was interdicted by the occurrence of severe cough and asphyxia. In the course of two days pus from the pulmonary cavity began to flow through the drainage-tube placed in the wound. The cough subsided and soon ceased, the offensive odor of the sputum disappeared, and the patient steadily gained in weight and strength. The discharge of pus from the cavity gradually grew less and less, and the drainage-tube was successively made shorter and smaller; but as soon as it was removed the fistula closed, and cough and expectoration returned. Resection of a rib and enlarging the cavity were practised in the hope of effecting closure, but to no avail. The fistula persisted. The patient, however, remained strong, and was able to do light work a year and a half after the opening of the cavity.

A Modification of the Treatment of Lupus by Tuberculin.—At a recent meeting of the Hamburg Society of Physicians, UNNA (*Deutsche med. Wochenschr.*, No. 44, 1891, p. 1224) presented two cases of lupus in which he had practised a modification of the Koch method of treatment, utilizing the tuberculin necessarily present in the bodies of the patients. The affected parts were covered with plaster, preferably of a kind exerting a favorable influence upon the disease, such as zinc-sublimate-plaster gauze or salicylated-creasote-plaster gauze, and then manipulated by massage. The procedure had been employed in ten cases. In the course of twenty-four hours the manipulation was followed by pallor of the diseased area, and upon repetition of the massage the characteristic reaction of tuberculin appeared.

A Large Varix of the Left Ary-epiglottic Fold.—JUFFINGER (*Wiener klin. Wochenschr.*, No. 42, 1891) has recorded the case of a man, sixty years old, with the symptoms of catarrhal laryngitis, in whom, on laryngoscopic examination, a tumor as large as a pea was found near the middle of the free margin of the left ary-epiglottic fold. The tumor was distinctly separated from its surroundings and was provided with a short pedicle. Its surface was smooth and spherical, and bluish in color. On deep inspiration the tumor was seen to be mobile and continuous inferiorly with a large vein coursing along the lateral wall of the larynx. The tumor was removed by encircling its pedicle with a wire loop, which was cautiously tightened during the passage of a galvanic current. The subsequent hemorrhage was slight and was controlled by the use of ice pills. The tumor, when removed, proved to be a quarter by a sixth of an inch in size, and histologically to consist of a congeries of dilated veins.

"Europhen," a Substitute for Iodoform.—VULPIUS (*Deutsche medicin. Wochenschr.*, No. 44, 1891) reports the results of a tentative employment of europhen at the surgical clinic of Czerny, at Heidelberg. Europhen is a fine pulverulent body, without decided or disagreeable odor, one-fifth as heavy as coarsely-powdered and less than half as heavy as finely-powdered iodoform. The agent possesses the advantage over iodoform in being readily soluble in alcohol, ether, chloroform, and benzin, and in less degree in fats and mineral oils. Europhen is not a single body, but is constituted principally of kresol-iodide and an inconsiderable proportion of an iodine combination soluble in water. Europhen possesses distinct antiseptic properties, and is but feebly toxic. Pain or eczema only exceptionally followed its application. Like iodoform, europhen occasionally formed crusts. The powder stimulated granulation, the granulations, however, displaying an undue tendency to bleed.

Gangrene Induced by Carbolic Acid.—In an inaugural thesis FRANKENBURGER records the observation that in susceptible individuals the protracted application of carbolic acid (even in dilute solution) causes a form of dry gangrene in those parts of the skin (even though uninjured) with which the acid comes in contact. The gangrene is caused by vascular stasis and thrombosis that are dependent upon a destructive action upon the red and white blood-corpuscles.—*Münchener medicin. Wochenschr.*, No. 43, 1891, p. 767.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment. When necessary to elucidate the text, illustrations will be provided without cost to the author.

SATURDAY, DECEMBER 26, 1891.

THE TREATMENT OF INFLUENZA.

LEESON (*Brit. Med. Journ.*, December 5, 1891) urges that isolation be resorted to as a preventive measure against influenza. He claims to have been successful in excluding the disease from a colony of three hundred persons constituted by the inmates and staff of an orphanage at Twickenham. The children were not allowed to go to church, the officers were prevailed upon to keep within the walls, and all visiting was prohibited. The disease exists on all sides, but the orphanage had thus far escaped.

He quotes BOLTON in fixing the incubation-period at five days, and believes that the disease is most readily transmitted in the earlier stages, so that a week of isolation (of the sick) will be sufficient. It is evident, however, that isolation of the well —the method so successfully adopted by LEESON at Twickenham, and by TRUDEAU two years ago at Saranac—will have to be kept up during the entire epidemic period, and that it is only practicable in institutions.

LEESON'S practice of giving "antipyrin in twenty-grain doses every four hours," while it may, as he states, have "a magical effect upon the pains," carries its own condemnation in his next sentence: "The treatment for the subsequent debility during convalescence is unsatisfactory."

This treatment was exceedingly popular during the pandemic of 1889, and was successful in achieving an unprecedented mortality. It is as irrational as it is dangerous. Influenza, whether directly by the action of the infectious agent, or more probably indirectly by the action of a toxic metabolin developed and retained in the system, is a depressing disease. It lowers vital energy. The indications are to favor elimination of the noxæ by stimulating all the emunctories, and to administer such agents as will reinforce the vital energy. Antipyrin and its congeners check excretion and depress vital force. They are thus directly antagonistic to the *vis medicatrix naturæ*, and directly synergistic to the toxic agents of the disease. It can hardly be doubted that many of the sudden deaths, and much of the undue prolongation of the course of a usually rapid disease, may be ascribed to the action of these drugs. They likewise retard convalescence and increase the liability to dangerous sequelæ.

There is no specific against influenza; but the derivatives of cinchona and of salicin seem most nearly to act as specifics. Cinchonidine salicylate, in doses of five grains repeated every second, third, or fourth hour, is of decided utility. Rest is important even in the milder cases. The diet should be simple, supporting, easily digestible, and readily assimilable. Carbohydrates should be given, preferably predigested, as in peptonized milk gruel, or as alcohol. The frequency of feeding, and the quantity of food, should be governed by circumstances. The skin, kidneys, and bowels should be kept in a state of healthy activity—by simple means, if possible. Niter, sodium benzoate, and spirits of nitrous ether, are among the best diuretics and diaphoretics. In a strong patient, at the beginning of an attack, the attempt to abort by profuse diaphoresis may be made—and, if free perspiration cannot otherwise be brought about, pilocarpine guarded by digitalis or strychnine may be employed.

The heart and nervous system should be sustained with strychnine. If indications for decided stimulation of the kidneys exist, either in previous disease or in present tendency to pleural or other effusions, cocaine, digitalis, caffeine, or sparteine may be added. Cocaine may find additional indication in gastric irritability, or in a tendency to subnormal temperature.

Antipyretics have no indication. The tempera-

ture is never in itself dangerous, and rarely rises so high as to cause serious discomfort. Cool or tepid sponging will usually afford relief from such discomfort as may, in a few cases, be experienced. Should there be exceptional cases of persistent high temperature, the ice-bag or other means of applying cold could be employed. Coryza, if troublesome, may be relieved by the administration of atropine or by the topical application of cocaine or menthol.

Laryngeal inflammation is a noticeable feature of the present epidemic. Edema demands scarification and hydragogue catharsis. Simple laryngitis is best treated by inhalation from steaming water of equal parts of compound tincture of benzoin and paregoric.

Pulmonary complications are not so serious or so frequent as in the recent epidemic. Counter-irritation, the ice-bag, or the poultice, followed by the cotton or wool jacket, and the internal administration of ammonium salts or terebinthinate preparations, constitute the best method of treatment. Ammonium salicylate is especially useful. In pneumonia we have seen much benefit from inhalation of ethyl iodide, as advised by BARTHOLOW. Pleuritis, pericarditis, and endocarditis are encountered, but the general treatment needs only obvious modification to meet the special symptoms. Blisters over the heart are useful. Acute rheumatism is prevalent, and appears to be modified by the epidemic influence. Blistering around the inflamed joints and over the heart may be advised; the administration of alkalies, followed by quinine salicylate, or in anemic cases, instead of alkalies, tincture of the chloride of iron, with strychnine hypodermatically in a decided dose, once daily, is useful. In cases presenting grave symptoms of whatever nature we advise inhalation of recently-prepared oxygen.

Pain does not furnish sufficient indication for antipyrin, phenacetin, and the like, to overcome the counter-indication afforded by their depressing properties. Opium preparations, especially codeine, or cocaine, or guarana, or even sodium bromide guarded by caffeine or by guarana, will usually relieve the headache, if the general measures already detailed do not accomplish this. In addition to these drugs, cannabis indica, hyoscyamus and its derivatives, compound spirits of ether, camphor and its bromide, and cold or hot local applications will be found useful in the relief of pain, when special treatment of that symptom is necessary.

The quick relief afforded by the coal-tar products is undoubtedly a great temptation to the physician who sees only what is immediately before him; and certainly many patients escape unfortunate consequences. Nevertheless, we must repeat that there is always danger, and that some of those escaping with their lives are so depressed that convalescence is unduly protracted, and the liability to morbid epiphenomena increased. The temporary apparent good is purchased at the price of much concealed evil. The management of convalescence is no less important than skilful treatment of the attack and its complications. Undue exposure must be avoided. Strengthening food and some simple tonic, such as tincture of nux vomica, or compound tincture of cinchona or fluid extract of coca should be given; or, if indicated by anemia, an arsenical or chalybeate preparation may be used for a few days or weeks or months, according to circumstances. After a severe and complicated attack climatic change may be desirable. Individuals known or suspected to be predisposed to tuberculosis should be kept under careful observation, and appropriate measures of prophylaxis should be instituted.

INFECTIOUS DISEASES OF SWINE.

THE subject of animal sanitation is deserving of the gravest consideration. The diseases of domestic animals, especially those communicable to man and those transmissible from animal to animal, bear an important relation to the health of the people and to the agricultural prosperity of the country. A thorough knowledge of the causes of these diseases and of their mode of propagation is absolutely essential to the intelligent and effective application of measures for their prevention. The national importance of this question has led the Government to institute scientific investigations of infectious diseases of animals, occasionally by commissions and permanently by the Bureau of Animal Industry. For several years this bureau has been engaged, in connection with its other duties, in investigating infectious diseases of swine. The results of these inquiries are summed up in a special report by DR. THEOBALD SMITH, and go to show that swine-plague and hog-cholera are two independent infectious diseases, each caused by an easily-recognizable specific disease-germ.

The frequent association of both hog-cholera and swine-plague in the same herd, and the occasional coëxistence of the bacteria of both diseases, as well

as of their respective lesions, in the same animal, have surrounded the investigations with difficulties and have often led to conflicting inferences. It is now claimed to have been well established by these recent experiments that the swine-plague is due to specific bacteria, and is identical with the disease *Schweineseuche*, prevalent in Germany. LÖFFLER first discovered the bacteria of *Schweineseuche* in 1885, but it remained for SCHUETZ to establish this disease in a more definite manner by his investigations conducted in the same year. Since then it has been generally recognized as a distinct infectious disease. In this country the differentiation of swine-plague and hog-cholera as distinct infectious diseases, though made possible by the investigations of the Bureau of Animal Industry in 1887, has not been thoroughly demonstrated until the present time.

SMITH has pointed out important morphologic, biologic, and pathogenic differences between the swine-plague bacteria and hog-cholera bacilli. The lesions in swine-plague are primarily and chiefly in the lungs, though the intestines may be, and often are, affected. In hog-cholera the primary disease is in the intestines, with secondary localization in the lungs. Bacteria similar to those causing the swine-plague have been found in the upper air-passages of healthy swine, cattle, dogs, and cats, but they possess a relatively feeble influence. It is highly probable that the disease-producing power of these germs is restrained by the absence of certain essential conditions, as susceptibility of the subject, suitable nidus for development, unhealthful modes of existence, and the peculiar environment to which the swine are subjected. As to the mode of infection, it is probable that the bacteria are introduced into a herd by infected animals, since the bacteria are speedily destroyed in soil and water. When once introduced, the spread of the disease throughout the herd is rapid. The manner of keeping the animals, age, breed, feeding, and the presence of parasites, all contribute to the production of a condition of susceptibility. Atmospheric conditions and the degree of virulence of the specific bacteria also have an important influence.

The means of prevention lie in the careful selection of stock and in the observance of rigid sanitation. When the disease has actually appeared, its spread is to be prevented by the adoption of the following measures:

1. Removal of still healthy animals to uninfected grounds or pens as quickly as possible.
2. Destruction of all diseased animals.
3. Careful burial or burning of carcasses.
4. Repeated thorough disinfection of the infected premises.
5. Great cleanliness, both as to surroundings and as regards the food.

It has not been demonstrated that the flesh of animals suffering from the plague is injurious to man, and therefore the question of its extinction is at present primarily a pecuniary one. The presumption is, however, that the flesh of such diseased animals should, upon general principles, be discarded as unfit for human food, and the law should so proclaim. The investigations of the Bureau of Animal Industry have led to decided advances in our knowledge of infectious diseases of swine. It is not claimed that the subject has been exhausted by these researches, but only that sufficient information has been obtained to enable a diagnosis to be made between the two principal infectious diseases to which our swine are subject, and to aid in the further study of the subject.

REVIEWS.

HUMAN MONSTROSITIES. By BARTON COOKE HIRST, M.D., Professor of Obstetrics in the University of Pennsylvania, and GEORGE A. PIERSOL, M.D., Professor of Histology and Embryology in the University of Pennsylvania. Large folio, 13 x 17 inches. In four parts, to contain about 150 pages of text, with 39 full-page photographic plates from nature, and many engravings. Price per part, $5. Limited subscription edition. Part I, pages 1–88, plates I–VII. Philadelphia: Lea Brothers & Co., 1891.

THE first part of this superb work can call forth little but praise from the conscientious critic. As a beautiful example of the art of printing it will at once strike and hold attention. The illustrations also stand out with a clearness and precision that at once please the eye and the scientific understanding.

The subject of teratology has long needed re-shaping and re-classification by the modern scientific intelligence, and the medical profession is to be congratulated that such competent men as Professors Hirst and Piersol have put their hands to the task. Up to the present time the best works on the subject are to be found only in the French or German language. Most of the material that has here been used for illustration has been taken from the rich collection of the Wistar and Horner Museums of the Medical Department of the University of Pennsylvania. In text and illustration, therefore, the work may justly claim a high degree of originality.

The classification of Saint-Hilaire has been used as a basis, with such departures and changes as are due to the great advances in embryology made since the time of the French author.

Especially valuable seems the *résumé* of the work done by numerous investigators in experimental or artificial teratology—a subject most difficult to make clear, because of its inherent mystery, but particularly because of the incomplete and inconclusive results so far obtained. Direct mutilation disregarded, violent agitation, marked variations in temperature, and disturbance of the normal respiratory interchange are forces that tend to produce alterations in the developmental processes of the embryo. But so far, no definite correspondence or relation between the artificial abnormalism of circumstance and the resultant malformation can be shown to exist.

The most noteworthy point of criticism, perhaps the only one that exists, consists in the entire omission of all reference to maternal impressions—fright, horrid sights, etc., as possibly productive of monstrous forms of the fetus. There can be no denial of the evident truth that up to the present science gives no definite answer even as to the existence of this agency. There is a vast body of ungathered testimony that strongly goes to prove the operation of this factor, while, on the other hand, there is much that may be brought against the theory. In such a work as this, one naturally looks for some epitomization of the discussion or some judicial expression of opinion upon it. Two sets of sound-waves in opposite phase may produce silence, and the query suggests itself if here a similar result may have come about as a consequence of composite authorship.

THE MODERN ANTIPYRETICS: THEIR ACTION IN HEALTH AND DISEASE. By ISAAC OTT, M.D. 8vo., pp. 52. Easton, Penna.: E. D. Voegel, 1891.

DR. OTT'S studies upon the production of fever are well known, and the present volume worthily supplements these researches by an experimental and clinical study of the action (physiologic and therapeutic) of the coal-tar derivatives now so largely, so recklessly, and so unscientifically employed in abating a symptom—elevation of temperature. Dr. Ott well says in his preface: "It is necessary to understand what fever is before we undertake the study of the agents which reduce it." He subscribes to the doctrine that elevation of temperature is not necessarily an indication of increased heat-production, but rather of a derangement of the normal relation between heat-production and heat-loss. An observation in the human calorimeter upon a subject of malarial fever is recorded, seeming to prove that heat-production may be lessened during the progress of fever. The chemistry of the coal-tar products is studied and their physiologic action in reducing temperature apparently proved to be exerted upon the nervous system. According to the author: "Fever usually is set up by a temporary increase of heat-production beyond that of heat-dissipation, whilst antipyresis usually is set up by a temporary decrease of heat-production beyond that of dissipation. In fever neither a high temperature nor an increased production of heat is a necessary concomitant; but as the temperature mainly depends upon an altered relation of heat-production to heat-dissipation, so in antipyresis neither a low temperature nor a lessened production is a necessary associate, but the fall of temperature mainly depends upon an altered relation of heat-production to heat-dissipation."

In the lower animals some of the antipyretics act upon heat-dissipation otherwise than they do upon man.

The chemical constitution of the antipyretics is thought to indicate the different activities of these bodies. Thus, "antiseptic properties predominate in the alcohol hydrate derivatives, as in naphthol, whilst the antithermic properties are most prominent in the amidogen derivatives, as in antifebrin, thallin, kairin. A predominance of analgesic properties exists in the amidogen compounds in which an atom of hydrogen has been substituted by a molecule of a fatty radical, especially of methyl, as in antipyrin, phenacetin, and exalgin."

Each agent is separately studied under the head of therapeutics, and its uses, according to the judgment of the author, briefly stated. A special study is made of the value of antithermics in typhoid fever. The author wisely concludes that high temperature, *per se*, is not dangerous, and that cold water, after the method of Brand, is far preferable to any antipyretic drug in the management of this disease.

NEWS ITEMS.

The Visiting Nurse Society of Philadelphia.—Physicians having patients among the poorer classes, unable to pay for continuous nursing, will find it advantageous to call upon the Visiting Nurse Society for such temporary nursing as may be desirable. The Society furnishes competent nurses at a moderate price per visit, or when patients are destitute, without payment. It is a charity in the best sense of the word. The office of the Society is at No. 1203 Race street.

CORRECTION.

In the issue of December 19, p. 710, seventh line from the bottom, in the article on "The Fundamental Principles of Anatomical Nomenclature," for *prëencephalon* read *prosencephalon.*

Two new cases of filaria sanguinis hominis, 649
Typhoid fever, 297
and insanity, 253
arthritis following, 653
laparotomy for intestinal perforation in, 591
rare complications of, 153
with low temperature, 188
Tyndale, Hilgard, pre-tuberculous condition, 425
Tyson, James, report of two cases of epilepsy, with albuminuria, mistaken for uremic convulsions, 507

ULCER, gastric, cured by a diet of ice-cream, 155
rupture of a duodenal, 131
Ulcerative endocarditis; autopsy; remarks, 129
Umbilical cord, bismuth subnitrate as a dressing for the, 713
Unique case of intussusception, 686

United States Medical Practitioners' Protective Alliance, 547
Unusual mode of transmission in a case of dermatitis venenata, 484
Untrustworthiness of the lay press in medical matters, 603
Uremic convulsions, two cases of epilepsy, with albuminuria, mistaken for, 507
symptoms, morphine for the relief of, 29
Urethra and bladder, disturbances from instrumentation of, 118
stricture of, and its treatment, 672
traumatic laceration of the, 659
Urethrotomy, external perineal, 714
Urine, maximum percentage of albumin in, 721
retention of, 301
sarcinæ in, 458
the proportion of albumin in, 717
Use of morphine for relief of certain uremic symptoms, 29
Uteri, pregnancy after conservative ventral fixation of retroflexed, 72
Uterine cancer, the radical treatment of, 641
hemorrhage, method of controlling, 104
tumors, 205

VACCINATION, treatment of pulmonary tuberculosis by, 47
Vagina, strangulation of, through a ring-pessary, 514
Van Hook, Weller, laparotomy for intestinal perforation in typhoid fever, 591
Varieties of chancre, 214
Varix of the left ary-epiglotic fold, a large, 740
Venesection in cardiac and arterial disease, 5
Vermiform appendix, removal of the, from a child twenty-two months old, for suppurative appendicitis; recovery, 512
Vertebra, fracture of twelfth dorsal, 417
Vision, impairment of, public institutions as sources of, 246
Vivisection, human, 137
Vocal bands, paralysis of, and icterus, 458
Voluntary control of muscles, remarkable case of, 599
Vomiting after chloroform inhalation, 105

WALL-PAPER, detection of arsenic in, 158
Wasdin, Eugene, case of ameba dysentery, with autopsy, 656
Washburn, W. H., causes and prevention of diphtheria in cities, 262
use of morphine for relief of certain uremic symptoms, 29
Washington as a meeting-place, 396, 582, 666
drinking-water, 525, 526
Water-supply and tapeworm, 46
Weagly, T. H., self-retaining palate retractor, 271; corrected illustration of, 498
Weekly cost of care of insane in American asylums, 51
